Another interesting item is that the same firm is offering a series of small carbon reproductions of the National collection (probably printed in Germany), and are underselling the modest price hitherto asked by the Englishman here, by some 33⅓ per cent. Of course, in the "Land of the Free" all this is perfectly legitimate, but it seems to be slowly and gradually drawing on the minds of the public that far too many facilities are given here to foreign enterprise.

The question has already been before Parliament, but with abortive results. I hope on the next occasion it will be brought forward in a form that will secure its deserved attention.—I am, yours, &c., J. Liddy.

34, *Tunley-road, Craven Park, N.W.*

RE THE AFFILIATION OF PHOTOGRAPHIC SOCIETIES.

To the Editors.

Gentlemen,—May I claim space to refer to the above matter now the excitement exhibited regarding it in several quarters appears to have bubbled itself out?

The object of the movement, as I understand it, is for the benefit of those societies affiliated. Each such society elects two delegates to look after its interests. Any failure of any particular society to reap in full such benefits as are available is the failure of its own delegates to do the duty entrusted to them, any failure of the scheme as a whole, again, being simply the individual failure of each delegate.

Is it a failure as a whole? or need it be? Speaking as a delegate on behalf of the Society I have the honour to represent, I should say, certainly not. Taking up the past year, we have had, through the Affiliation scheme, at least five or six important lectures and demonstrations given us by well-known workers, and in return fifteen or sixteen lectures and lantern shows have been given by our members before other affiliated societies. These figures are well within the mark. Again, our members saved 1*l.* 5*s.* alone on admission tickets to the last Pall Mall Exhibition. Then we have had twenty-four numbers of the Royal Photographic Society's *Journal*, representing a cash value of 1*l.* 4*s.* Again, such of our members as were interested in the subjects attended the series of lectures just concluded, and paid for admission at the rate of twopence per lecture. But enough of this. Our subscription for these and other benefits is one guinea per annum. We are told in the old Book "to such as ask shall be given;" and, in regard to this scheme it is certainly no exception to the rule that "self help is the best help," and it is just this—Each society is supposed to elect representatives to do for them, viz., look after their welfare.

So far what has been said has been so said as a delegate. Now I would crave your indulgence yet a little further, that I may, as Chairman of this scheme, make one or two statements regarding it.

The series of six lectures recently given on the subject of *Photography with the Bichromate Salts* are to be published in pamphlet form, and copies will be sent each affiliated society free.

In order to extend the series of papers, lectures, &c., available for use of our societies, commissions have been placed for six fully illustrated lectures, being prepared on the following subjects:—

Pictorial Photography, by Mr. A. Horsley Hinton; Lantern Slide-making, by Mr. John A. Hodges; Negative-making; Architectural Photography, by Mr. H. W. Bennett; Intensification and Reduction, by Mr. J. McIntosh; Hand-camera Work, by Mr. W. Thomas.

These lectures, the first five at any rate of which certainly are in the hands of gentlemen eminently capable of handling their respective subjects, will be ready for circulation among affiliated societies early in October, and, as funds will allow, others will follow; but, for one year's work, twelve important lectures by experts looks somewhat unlike that moribund condition of things some would persuade the world at large exists within the camp of affiliated societies.

That there exists ample call for some such organization is clear. What we want is help. We want workers; for such there is room. Mere idle vapouring about other people's failures we have no room for, and I have taken the perhaps uncalled-for course of troubling you and your readers with this somewhat lengthy letter in order that those societies scattered about this country of ours, who only come in touch with matters of this kind through the photographic papers, may know that, if the good ship *Affiliation* is to sink, she does so "scuttled," and the gallant little band of delegates who have stood round me since my election to the chair are determined, when the end comes, if it does come, we go down with flag flying, and firing our last broadside, leaving the responsibility to attach where it should.

But are we doomed? The need for existence is still with us, and I would ask each society affiliated to see that those it elects as representatives fulfil the functions entrusted to their hands. To unaffiliated Societies at all interested in this or some similar movement I would commend the matter to their careful consideration, "for many littles make much," and with funds sufficient to work on a great deal of the trouble many societies find in providing for programmes, &c., might be lessened.

Apologising again for taking up so much of your space,—I am, yours, &c., W. Thomas, *Chairman.*

Answers to Correspondents.

*** *All matters intended for the text portion of this* Journal, *including queries, must be addressed to* "The Editors, The British Journal of Photography," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* Henry Greenwood & Co., 2, *York-street, Covent Garden, London.*

Photographs Registered:—

Mrs. J. E. Oatey, Wadebridge, Cornwall.—*Two photographs of Albert J. Henwood, Padstow, Cornwall.*

Richard Bailey, 35, Storey-square, Barrow-in-Furness, Lancashire.—*Photograph of H.M.S. "Powerful" in the Devonshire Dock, Barrow-in-Furness.*

Frank Coghlan, 31, Carlisle-road, Londonderry.—*Photograph of head and shoulders of the Rev. Denis Quigley, C.C., Londonderry. Photograph of the Rev. Denis Quigley, C.C., Londonderry. Three-quarter length cabinet.*

John Owen, 49, Broad-street, Newtown, North Wales.—*Photograph of Plas Machynlleth, with group of Royal party. Three photographs of group of Royal party at Plas Machynlleth. Photograph of the Royal procession at Machynlleth, June 25, 1896.*

George Taylor, 5, South-road, Bishop Auckland.—*Photograph of Bishop Auckland Football Team, winners of the English Association Amateur Challenge Cup, 1895-6. Photograph of Bishop Auckland Football Team and officials of the Club, winners of the Eaglish Association Amateur Challenge Cup, 1895-6.*

RECEIVED.—T. S. BRUCE; SOLIO; F. COGHLAN; and others. In our next.

A. LOMAX.—Sorry we are unable to print your letter as it stands.

A. H. CADE.—The firm, we believe, is a respectable one. Probably they are offering bromide enlargements.

ACETO asks where calcium carbide can be obtained, and the price?—In reply: Almost any dealer will procure it for you. The price ranges between 4*d.* and 1*s.* per pound.

ASSISTANTS AND THEIR GRIEVANCES.—JOHN A. RANDALL; SIDNEY LYDFORD; G. C. LAWS. We withhold your letters, as the subject has now been fully ventilated. Thanks, nevertheless.

VARNISH FOR NEGATIVES.—C. BIRD. As the varnish dries with a more or less matt surface when applied cold, try warming the plate before its application, and dry with a moderate heat.

ANILINE DYES.—W. A. T. If the colours you propose to use run, and we doubt if they will, employ those only soluble in alcohol. Why not use the colours specially sold for the purpose? there is no difficulty with them.

STRIPPING COLLODION NEGATIVES.—T. BENDON. It is quite a matter of opinion as to which is the best, French chalk or beeswax, for preparing the glass with; both answer well if properly applied. The former is perhaps the least trouble in application.

EXPIRATION OF AGREEMENT.—B. W. As the agreement was for a certain and definite term, no notice of its termination is necessary from either side. It might, however, be courteous to notify some little time ahead when it terminates, as the fact might possibly be overlooked.

SALE OF BUSINESS.—SOLD. Taking your statement as being correct, there is no doubt you have been taken in; but your difficulty will be in proving that the amount the books show was not taken, or that it was not taken as *bonâ-fide* business. If you can show that, then you will succeed in obtaining a return of the money or a portion of it.

SILVERING MIRRORS.—W. P. D. writes: "Can you inform us how to silver mirrors used in process work"—Martin's method is generally considered the best, and it is given on page 879 of the ALMANAC for the current year. Silvering mirrors is a very simple operation, though it requires some little practice to do it with certainty.

STAINED CLOTHES.—J. KINSLEY says: "Having unfortunately spilt pyrogallic acid on a light pair of trousers, will you kindly let me know which is the best means or way to remove it?"—We know of no way of taking out the stain without also interfering with the original dye of the fabric. The best way will be to send the garment to a dyer's to be dyed a darker colour.

EVELOPER.—DEVELOPER says: "I have been taking several views lately, and I cannot settle to a developer. Would you please state through your paper which developer would be the best—pyro ammonia or pyro soda—for good brisk negatives that are wanted for views?"—In reply: You had better employ whatever developer is recommended for the particular brands of plates you use.

PYROGALLIC ACID DEVELOPER FOR COLLODION NEGATIVES.—BRADFORD. Yes, wet-collodion negatives can be developed with pyrogallic acid acidified with acetic acid. Indeed, that was the developer that was always used in the early days of the process, when only iodised collodion was used. When bromo-iodised collodion was introduced, iron developer was found better, if the image was afterwards intensified with pyro and silver.

ENLARGING ON BROMIDE PAPER.—J. CARPENTER says: "Enclosed please find two bromide enlargements to show what I complain of. You will see they are of a cold and inky tone, and I can get no other. I have tried different papers, but they are all alike. I use the ferrous-oxalate developer. Can you help me with a hint or two?"—The cold tone is fully accounted for by under-exposure and forced development. Give longer exposure—double at least—and more satisfactory tones will be obtained.

A LOVERS' QUARREL.—IN A FIX says: "I had a young man and woman come to have their photographs taken together, for which the young man paid, and then the young man paid for six *cartes* of the young woman by herself. Since then they have fallen out, and the young woman forbids me giving the single photographs to the young man, and the young man demands them because he has paid for them. Will you let me know the best thing to do in the matter?"—Legally, we believe, as you did not receive payment from the young woman, you are entitled to let the young man have the photographs; but we should advise you to return the money, and decline to part with the photographs to either party until the quarrel has been smoothed over—such quarrels usually are.

PROCESS BLOCKS.—COUNTRY TYPO says: "One of my customers has supplied me with what he calls 'process blocks' to use in printing some hand bills for him at a cheap rate. I sent them in, and he has returned them, as the illustrations are so bad, and he shows me the proofs he received with the blocks, but they are printed on a very fine-surfaced and costly paper. Such impressions I find it impossible to get on the common paper I have to use. Is this the case with process blocks generally?"—Yes. Fine process blocks are quite unadapted for rough printing on common paper. It is a pity that you did not supply proofs, and explain that they were the best that the blocks would yield under the circumstances. Had your customer supplied the paper, you would have had a better case in the County Court than we fear you have now.

EMBOSSING PRINTS.—ENAMEL asks: "Where can I obtain masks or dies suitable for embossing enamelled prints? I propose to do several at one time, and use the ordinary letterpress to obtain the pressure. I do not see anything of the kind in dealers' lists, excepting so-called embossing presses, which do not meet my views either in price or practical value."—All who supply embossing presses will, doubtless, supply the masks and dies without the presses, and will, doubtless, do so cheaper than any ordinary brass-worker would make them to order. Try such houses as Marion's, Adams', Fallowfield', &c.

BOOK ON PHOTOGRAPHIC CHEMISTRY.—H. K. E. says: "I have Meldola's *Chemistry of Photography;* but, as I have not had any instruction in chemistry, I find the work too far advanced, and shall be pleased and obliged if you will recommend a suitable work that would be a 'lead up' to the one mentioned. If such a one is issued, one that will teach elementary chemistry, but principally as applied to photography, is, I think, the one I want."—In reply: There is really no book which entirely meets our correspondent's requirements. A book on the elements of organic and inorganic chemistry (to be obtained of any educational bookseller), Leaper's *Materia Photographica* (Iliffe, Coventry), Hardwich's *Photographic Chemistry* (J. & A. Churchill), will, however, probably supply between them a good introduction to Meldola's book.

MOUNTING STEREOSCOPIC SLIDES.—A. E. M. To answer your letter of eight closely written pages in detail would involve the occupation of far more space than we could spare. You had better consult the 1887 volume of the ALMANAC, where the late Mr. Traill Taylor deals with the subject of *Stereoscopic Photography* in a very full manner. In the meanwhile, the following replies to your queries suggested by the prints you enclose may be of service to you. 1. Too wide apart; you have them three and a half inches; they should not exceed three inches, and are better if only separated two and three-quarters. 2. No wonder you do not get a good effect with this slide—the picture has not been transposed in mounting. 3. Clearly the nearer the subject the nearer should be the centres of the lenses; thus, in taking portraits of a sitter removed from the camera only seven or eight feet, a separation of two and a half inches is ample. 4. Donnadieu's book has not been translated into English.

NEIGHBOURS.—AMATEUR writes as follows: "My next-door neighbour and I are not on very good terms. I have put up a studio in my garden, in which I intend, eventually, to carry on a portrait business. When I commenced to build he tried to stop the erection, but the District Council would not hear of it, as they said it was quite within their by-laws. Now my neighbour is building up his side wall, and adding another room or two to his house, which will quite stop out my principal side light, and this, he says, is his main object. Can I stop him by any process less costly than an injunction in Chancery?"—No; nor by an injunction in Chancery. Any one is entitled to erect anything he likes on his own premises, provided it does not infringe the Building Act. If your studio had been up sufficiently long—not less than twenty years—to entitle you to "Ancient Lights," the case would be different. Then the Court of Chancery would give you redress; as it is, you have none.

ANHYDROUS SODIUM SULPHITE.—C. H. C. says: "On account of the tendency of the crystallised form of sulphite of sodium to decompose by heat, and on account of the small quantities used by most amateurs, requiring frequently the loss of half-a-pound bottle or more, I have been trying for some time to use the chemical in its dried and powdered form, in which condition it seems to keep perfectly and to be unaffected by heat. It is difficult, however, to know what quantity to use in place of the crystals, and I am unable to get an answer to the query here. You will greatly oblige if you will give some definite rule or formula by which, the proper quantity of the crystals being stated, the equivalent quantity of the dry chemical can be ascertained."—We presume that our correspondent means that he is using anhydrous sodium sulphite. In that case, as, roughly speaking, the ordinary sulphite has seven parts of water of crystallisation, about half the quantity by weight of the anhydrous salt should be substituted for it.

PRINTING TROUBLES.—PAPER says: "Lately, in fact for some months past, I have been troubled with wretched ready-sensitised paper (sample enclosed), and write to ask if you will be kind enough to give your opinion on the following:—Cause of mealiness, whether it is due to sensitising or if it is, as the traveller says, 'already in the paper, when purchased by their firm?' Also, can you recommend a thorough good paper? If not, will you be kind enough to say the best means to keep paper which you make yourself, as I find mine has a decided tendency to turn yellow before the evening, when I tone? Would the bath being slightly acid help me? The paper I use takes a lot of gold and also a fearful time to tone, and the prints, when finished, are really fit only for the waste-paper basket."—Without trying the paper, in the condition it is received by the sensitisers, we cannot, of course, say whether it is their fault or that of the albumenisers, or the makers of the raw paper. It is against our rule to recommend any particular maker's wares. The sensitising bath should be decidedly acid, or the paper will not keep this weather. If the paper, both before and after printing, be stored between sheets of blotting-paper that has been moistened with a solution of carbonate of soda, and allowed to dry, its whiteness will be retained for a much longer time. The print sent seems very much as if the paper was in an abnormally dry state when it was printed; if so, that might account for the mealiness and the length of time taken in toning. Try the effect of placing the pads and backs of the frames in a damp cellar for twenty-four hours, and the paper in the same place, for a few hours before printing. That will possibly get you out of your difficulty.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1888. Vol. XLIII.—JULY 10, 1896.

Contents.

EX CATHEDRÂ.

We have received the prospectus, dated May, 1896, of the Institute of Photographic Artists "to be incorporated." The Institute, through its President, invites professional photographers to become members. The leading objects of the Institute are, briefly: To provide for (*a*) an organization of photographic artists, &c.; (*b*) the better definition and protection of the profession by the issue of certificates of membership, examination of pupils, &c.; (*c*) opportunities for intercourse, reading of papers, lectures, &c.; (*d*) the administration of a charitable fund; (*g*) and "other lawful things."

* * *

Membership is open to professional photographers, and their assistants may become "students" of the Institute. A London Fellow is asked to pay 2*l.* 2*s.* a year subscription, and 2*l.* 2*s.* as an entrance fee. Then there are Associates, who pay half these sums, and country Fellows and Associates. Fellows may put F.I.P.A. after their names; Associates, A.I.P.A. But the Institute does not intend to grant degrees. We gather from the proposed Memorandum of Association that, *inter alia*, the President and Secretary are to hold office in virtue of an agreement which has already been prepared and made between those officials and the Company.

* *

The prospectus is backed by, among other names, that of the President, Lawee Harris, Esq., F.I.A.S., whose only address is vaguely given as South Kensington; and that of the Vice-President, E. L. Toller, Esq., F.I.S.E., who just as vaguely hails from East Dulwich; while, of the Provisional Council, H. H. Robinson, Esq., F.S.I., merely dates from Brondesbury. The Standing *Council (sic)*, Bankers, Organizing Secretary, and Secretary are named, but, while the latter official is said to live at West Brompton (which, like South Kensington, is a large suburb to date from so unprecisely), the offices are set down as at 61 & 62, Chancery-lane, W.C.

* * *

We are sorry to have to point out that the ground proposed to be covered by the Institute of Photographic Artists is already occupied more or less by existing photographic bodies, so that the necessity for the foundation of the Institute has possibly not been established. We are unacquainted with the names of the gentlemen who are promoting the Institute—a fact which we state for the information of those of our readers who may have received solicitations to become members. As to the scheme itself, we decline to express any opinions; but we venture to say that, if the Institute secures a membership in the exact ratio of its intrinsic value and possibilities, nobody will have any just cause for complaint.

* * *

The presence on our table of Messrs. Sands, Hnuter, & Co.'s second-hand list of photographic apparatus gives us the opportunity of stating, in answer to some questions that have reached us this week, as well as for the benefit of our other readers, that this firm also makes a speciality of lending out cameras, lenses, &c. on hire. The charges appear to be very reasonable, and the address of Messrs. Sands, Hunter, & Co., is 20, Cranbourn-street, Leicester-square, W.C.

* * *

Last week, at the bazaar held at Queen's Hall, Regent-street, in aid of the Actors' Orphanage Fund (when, by the way, let us ask, will photographers and their assistants take the formation of a similar fund in hand?) photography of the

"while-you-wait order" was one of the means adopted by the fair organizers of the bazaar for increasing the profits. This photographic department was under the control of the charming Miss Letty Lind, with professional assistance, and a "Duplex" machine, the invention of Mr. L. Nievsky, was used. An example of the pictures thus (automatically) produced is before us, and, though the prices charged, in the name of charity, were such as would make a photographer very envious, there is no reason to be dissatisfied with the quality of the results, which are good examples of this class of tintype, the more especially as the portraits were taken in a balcony lighted from the side only.

* * *

A PROFESSIONAL reader, Mr. Frank Coghlan, of 31, Carlisle-road, Londonderry, draws our attention to the prospectus of a midsummer *fête* held in his town on June 25. Among the attractions is listed, "Artistic photography by the following ladies and gentlemen." Here are given the names of seven young ladies (they are all "misses") and eight gentlemen, who undertook to deliver photographs within one week at the prices of one shilling each for cabinets, and sixpence each for *cartes-de-visite*. We do not gather from the prospectus that the *fête* was held on behalf of any charitable institution, but we presume it was. Our correspondent thinks we should comment strongly on this matter, and condemn the principle; "if not, amateurs will shortly drive professionals out of the field." We, however, prefer to dismiss these suggestions with the remark that, as a rule, professional photographers are amply avenged by the quality of the results turned out by amateurs on these and similar occasions.

* * *

AN announcement, published in our advertisement columns last week regarding the photographing of 210 babies in seven hours with a hand camera, has brought us a communication on the subject from Mr. Owen Brooks, Photographer, of 83, Dewsbury-road, Leeds, who desires to correct Mr. Jenkinson, of Broken-hill, when he thinks no one has ever taken more babies in one day in a studio, and it would be utterly impossible with an ordinary camera. "In May of 1892, I advertised that, on the 30th and 31st, for seven hours each day (from nine to one and one till five), I would take all babies free, and give one cabinet to each mother. In the two days we took 625 babies' photographs, using an ordinary camera. For this, on June 18, 1892, I was awarded the 'Sloper Award of Merit' and the title of 'Champion Baby Photographer.'"

* * *

WE are pleased to give Mr. Brooks the opportunity of informing our readers by what feat of photographic dexterity he acquired the two distinctions that have been conferred upon him. Of course, like other champions, he must be prepared to maintain his title against all comers, and, as a result of this publicity of his powers, we should not be surprised to find that title, honourable as it is, subjected to the challenge of some ambitious rival. But, seriously, are these methods of attracting business profitable, and do they not sāvour somewhat of what our brother photographic editors in America term "Cheap John"-ism!

RÖNTGEN WORK FOR PROFIT.

So much has now been written on this topic that photographers are beginning to ask, "Is there money in it?" a sure sign of growing interest. The question, however, is one that cannot be answered with a plain "yes" or "no." Everything depends upon surroundings. At the outset it seems to be found that few "sitters" are to be had who will give a paying fee out of pure personal or scientific interest for any Röntgen picture of any limb or portion of their body. If a fee is to be had, it will simply be from those who require surgical diagnosis of injury, malformation, or disease of internal structures, such as can be given by this means alone. At present the main source of supply of "New Light" pictures is, firstly, one or other of the surgeons who have taken up the practice of Röntgen work as either an interesting study or for actual use in their profession. Secondly, there is also over the country a large number of scientific enthusiasts who have given great attention to the subject, purchased valuable apparatus, and made themselves thoroughly *au fait* in taking these electro-sciographs, and they have been utilised by resident surgeons for obtaining the desired representations of the lesions of such portions of their patient's frame as they are desirous of investigating. This is probably done without charge, and the professional photographer will be apt to imagine that they would interfere with any possible profit he might make.

Further, the use of the fluorescent screen lessens the need for photographic intervention, so many cases being at once diagnosed when the fluorescent picture is seen. It will, however, if the photographer is to make money out of the process, be just as easy for him to either let his surgeon clients observe the fluorescent picture alone, or to take a negative as a permanent record. There would need to be little or no difference in the fee to be charged, seeing that the capital expenditure is the same, and the time needed for putting the apparatus in working condition not much less in either case.

These preliminary aspects of the subject being duly considered, the photographer is in as good a position as possible for discovering for himself whether there is anything to be made out of Röntgen ray work. He has first to consider the capital expenditure involved, the cost of wear and tear, the probability of sitters. Our own opinion, given with every reserve, is that there ought to be, in fairly large centres of population, quite a sufficient number of cases to make it pay; and, of course, the mere bringing of patients as sitters would aid in stirring business. We hope that ere long there will be a sufficient number of professional workers who will be able to give us the benefit of their actual experience, and we should be very pleased to have the opportunity of publishing any remarks they could make.

The subject of outlay has already been treated by one of of our contributors, whose figures may be relied upon, and, if even we substitute for the Grove cells the more expensive well-known bichromate battery, with the removable elements, the best form of which is sold at about 4*l.*, we find 15*l.* or 16*l.* represents the needful outlay with a three-inch spark coil. This size is a really good working instrument, moderately quick in action; but, if deep structures are to be sciographed, a five or six-inch spark coil must be used, and it would increase the first outlay by from 5*l.* to 10*l.*

These sums do not include the fluorescent screen, and it cannot be doubted that the best opinion runs in favour of those made with platino-cyanide salts. These substances are just about as dear as, or probably a little dearer than, chloride of gold, and some conception of the cost will be found when it is stated that nearly an ounce would be required for a 12 × 10 screen.

The tungstates are chosen by some workers, but the ordinary

kind of calcium tungstate does not answer in the hands of many workers. Messrs. Hopkins & Williams, however, sell a special kind, at about four times the price of their ordinary description.

Mr. Edison's screens, so much talked of, do not seem to have been tried to any practical extent. In using fluorescent screens it is desirable to take the sciograph on a celluloid film, for it is the general opinion that, if the screen is placed between hand and plate, an unpleasant amount of granularity is produced; but, by placing the fluorescent tablet on the table, then the celluloid film, sensitised side towards the tablet, and, lastly, the object to be sciographed on the top, the best effect will be obtained, the thickness of the celluloid producing no appreciable diminution of sharpness. The use of the screen by the universal consensus of opinion greatly reduces the exposure.

The mode of employing the screen simply as an exhibition surface is self-explanatory so long as it is remembered that the observer should be in complete darkness when making his observations. With regard to the pattern of Crookes' tube to select, the general verdict is unanimously in favour of the Jackson pattern, both for the sharpness of image and rapidity of exposure. It must be observed, however, that already several important applications of modifications of the principle of this tube have been described, and, as time progresses, we are likely to have further improvements. If any one possess one of the older patterns of Crookes' tube, he can, of course, improve its sharpness just exactly as he would the defining power of a bad lens by the introduction of a diaphragm, which can be satisfactorily made by punching an aperture in a sheet of lead. This, as we need not observe, while increasing sharpness by reducing the emitting area, increases the exposure *pari passu*, and not at the rate of a lens diaphragm.

Finally, we would say that, in fixing his charges, the photographer must bear in mind that much time is consumed in the work, and the tubes, even apart from inevitable breakages and damages, will not last for ever; but, whether he find the adventure at once profitable or not, it would undoubtedly be a most excellent advertisement, and thus indirectly a source of profit.

DEVELOPING FORMULÆ.

It may seem rather late in the day to refer to a matter that would seem to have been thoroughly threshed out years ago, but it is probably because the subject is so apparently well understood that the desirability of once more calling attention to it arises. The circumstances that led to our now referring to the matter are as follow.

A short time back a number of negatives were submitted to us with a view to our expressing an opinion as to "what was the matter with them," and the verdict given without any hesitation was that they were much under-exposed. This was also the view of the owner of the negatives, but it was not shared by the makers of the plates, and hence the appeal to us. The plates were one of the leading brands of the highest rapidity, the exposures were all made out of doors, and were of the ordinary every-day run of snap-shot subjects, averaging about one-tenth of a second. So far there was nothing whatever to account for the results, for, with those or even much slower plates, the exposures ought to have been ample. A couple of the plates were given us to try, and under precisely similar conditions gave two faultless negatives, remarkable for the brilliancy and crispness of their detail, and their general air of "robustness," whereas those previously exhibited had been thick and muddy, and utterly devoid of any half-tone, to say nothing of shadow detail.

The conditions, we repeat, were identical, so far, at least, as choice of subjects and exposure were concerned, but development remained to be considered. The faulty negatives had been produced by means of the maker's own formula, ours were developed according to our own judgment of the treatment required under the circumstances and knowing the general characteristics of the plates. It may seem absurd to say it, but the cause of failure consisted solely in adhering too closely to the printed instructions issued with the plates.

At the present time, in the competition for the highest possible degree of rapidity attainable, it is perhaps quite true to say that more depends upon the development than upon the plate, or, at least, that the most rapid plate in reality may prove in practice much slower than it really is if not properly developed. Plate-makers therefore have worked their developing formulæ out in such a manner as to get the very utmost out of a plate under the most trying conditions. We are speaking of the ultra-rapid brands now obtainable, which in fact may be said to embody in their instructions the formulæ calculated for working the plates at high pressure, or under the least favourable conditions.

For instance, we read of plates speeded as high as 200, 300, and even 400 Hurter & Driffield, figures which, to the majority of workers, are practically meaningless, but may be faintly grasped when we say that on a bright winter day with a plate marked 50 Hurter & Driffield, and the lens working at *f*-22, we have had no difficulty in taking "instantaneous" outdoor groops in about one-tenth of a second. If we compare the value of the light in, say, January with the present time, it is almost impossible to estimate what would be the corresponding exposure requisite under similar conditions with a plate speeded at 400 Hurter & Driffield, in fact, for such work such a plate is not only unnecessary, but is actually a nuisance. The class of work for which such films are specially adapted is chiefly confined to rapid portraiture under adverse conditions of light, interiors and suchlike, when they undoubtedly prove most valuable aids, and it is in connexion with this kind of work when the full powers of the plate are required that the formulæ are calculated.

But, when plates of this degree of rapidity are applied to ordinary, every-day work, it savours somewhat of the use of the steam hammer to crack a filbert; and, though such application is perfectly possible, it necessitates something more than ordinary care to ensure success. In the case of the negatives to which we have referred, the plates were not of anything like the abnormal rapidity just spoken of, but something like 150 by the Hurter & Driffield measurement, a sufficiently high degree of rapidity, however, to require more than ordinary care when employed for well-lighted outdoor subjects, with even very short exposures; and yet, when we came to compare notes in the matter of development, we found that our unsuccessful friend had been using no less than two and a half times the quantity of alkali, and one-fourth the restraining bromide that we had ourselves employed in producing successful negatives.

The moral of this is that, although it is always a commendable practice to follow the instructions given with any make of plates, it is equally desirable that some judgment should be exercised, and in this connexion it should always be borne in mind, as has been frequently pointed out in our columns—and elsewhere—that the maker's formula generally

represents the strongest possible form of developer the plates will stand, when necessary; and that, for ordinary work, when the pressure of conditions is not great, it may be, and indeed should be, considerably modified.

Looked at from this point of view, there is scarcely a published developing formula of the present day that will not bear to have the proportion of restraining bromide at least doubled for ordinary work, and the alkali probably, at the same time, considerably curtailed. The worst that can happen, if this course be followed, is a slightly prolonged development, while, in case the exposure shall have been misjudged, there is a much wider margin for correction than would be possible if the developer were working at its utmost power.

The Guildhall Exhibition.—The loan collection of pictures in the Corporation's Art Gallery is attracting a large number of visitors, particularly on Sundays. We may remind our readers who have not yet visited the Exhibition, and intend doing so, that it closes at the end of the current month. The show is open from ten till seven on week days, and from three till seven on Sundays.

X Rays: Further Discovery.—The latest discovery, if it is possible to get "the latest" into print before a later is discovered, in connexion with the Röntgen rays, comes from Berlin. It is said that a physician there has found that the stomach and intestines can be photographed by the aid of the X rays, provided they contain solutions of metallic salts; which, he says, he finds just as impenetrable to the rays as the metals themselves. The bones, which are composed chiefly of lime, are the most impervious by the rays, of all parts of the body and it is now claimed that preparations of lime, even including lime water, are equally as opaque to them. This discovery ought, if it be as stated, to lead to further useful developments of X ray photography.

An Interesting Photograph.—Li Hung Chang is just now "the lion" on the Continent. It appears that, on his visit to that veteran statesman, Prince Bismarck, at his residence at Friedrichsruh, the two were photographed while sitting together on the terrace. The photograph has since been published in Berlin, and, we are informed, is meeting with a ready sale there. As the Celestial statesman will shortly be in this country, there is no question that enterprising portraitists here will be soliciting sittings from him, but how many will be accorded remains to be seen; also, whether the portrait will be much in demand by the British public. As a rule, the Chinese are not, or were not, much given to having themselves photographed, and generally sit with reluctance.

International Copyright.—The eighteenth congress of the International Literary and Artistic Association will be held at Berne, from August 22 to August 29. The proceedings will turn more especially on the question of literary and artistic copyright, and photography will not be overlooked. The international copyright law has been a great boon to painters, as well as photographers, in preventing the piracy of their works in foreign countries—or at least in those which are signatories to the Berne Convention of 1887, and they include the greater number on the Continent. English artists now suffer most from the piracy of their works at the hands of America. There their work is pirated in the most unscrupulous manner conceivable, as many English and Continental publishers know to their cost.

The Jackson Polar Expedition.—The steam yacht *Windward*, which started from Vardö to Franz Joseph Land one day last week, presented a very interesting appearance on her decks. In one part were stalled several teams of reindeer, in another a number of sheep, while amidships were stowed a large quantity of provender for them and stores generally. Huge ice saws and drills for clearing a way through the ice were very prominent on board. It is anticipated that the expedition will be in communication with Mr. Jackson by the end of this month or the beginning of next at the latest. It is to be hoped that this expedition, which has been so considerately planned, will be more successful, photographically and otherwise, than several that have preceded it. Many are also anxiously looking forward to the results of the balloon expedition to the Pole, as well as to the safe return of the intrepid voyagers.

The Royal Wedding.—The forthcoming wedding of the Princess Maud of Wales with Prince Charles of Denmark has been a good thing for those who have negatives of the royal pair, or of one or other of them. We are given to understand, through the trade, that the sale of the portraits has been exceedingly large ever since the announcement of the engagement was made, and still continues. This is, no doubt, due to the fact that the marriage is popular, and also that the Princess Maud, like all the Princesses of Wales, is a general favourite with the British public. It is announced that, after the wedding, there will be a grand procession of the royal party, which will include the Prince and Princess of Wales, the King and Queen of Denmark, and others of the Royal Family, from Buckingham Palace to Marlborough House, by way of St. James's-street and Piccadilly. As the time of day and season of the year will be propitious for rapid photography, there is little doubt that plenty of cameras will be seen on the route. W may call attention to the fact that cameras, even hand cameras they are seen, are not allowed in the park without a permit.

Chelsea Reach.—The London County Council does not seem to be adding to its popularity by the way it spends some, at least, of the ratepayers' money. Certainly it does not amongst artists and admirers of the picturesque generally. Just recently there was a general outcry by artists and residents in the neighbourhood, as well as the public generally, as to the way it proposed to despoil the beauties of Hampstead Heath by clearing off furze bushes, levelling up its hollows, and cutting it up with gravelled walks, according to the usual "taste" of the Council. Now it proposes to destroy the picturesqueness of Chelsea Reach, which has always been a happy hunting ground for artists, and several letters protesting against the scheme have appeared in the "dailies." Where boats and barges with their brown sails are, there can good pictures be made, even though they lie, at low water, on evil-smelling mud banks, as every photographer knows quite well. There is, however, also the question of utility, which must receive consideration. Many of our older readers will remember the picturesqueness of the Thames banks before the Victoria and Albert Embankments were constructed. The latter became necessary to preserve the great highway; but whether the same is the case with Chelsea Reach is very questionable. Baths it is considered by the Council are required at this point, and to provide them there must be an embankment, which will, of course, quite do away with the beauties of the Reach. London, and the Thames banks in its vicinity, can now ill spare any of its remaining beauty spots, and we would fain hope that this one may yet be spared us; but, in this utilitarian age, the useful generally receives more consideration than the æsthetic; though this does not always apply to the London County Council. It, in its "taste," would often destroy the latter without in any way contributing to the former—the spoliation of Hampstead Heath, to wit.

PHOTO-MECHANICAL NOTES.

THERE has always been a great deal of mystery, which, indeed, still exists, as to who was the actual inventor of the fish-glue process for half-tone printing, and what led to the use of such an odd substance. The process has been variously ascribed to Mr. F. E. Ives, Mr. Max Levy, Mr. M. Wolfe, Mr. W. H. Hyalop, Herr Heimbecker, and other American workers; but it has always been thought that Mr. Ives had the best claim to the origination of it. That gentle-

man, however, recently stated this to be a mistake, at least so far as the use of fish glue is concerned. Mr. Ives certainly did bring into use a process of burning in an "enamel" resist on copper plates in half-tone photo-engraving. He says the process was developed under his personal supervision, and was used for some years for producing blocks from his negatives before any one else adopted a similar method: it was not, however, his invention, but a modification of a French photogravure process, the formula for which was found in an old year-book. The man who did most of the work of experimenting and developing the process was an Englishman named Purton. The use of fish glue was introduced some years after the method was started, the material at first employed being a mixture of albumen and gum arabic with a little honey or glycerine to make the film hygroscopic, development being effected originally by dusting with a powdered tin salt, which prevented the formation of the hard "enamel" by heat on those parts where it adhered. The use of the tin salt was afterwards abandoned, and the washing out relied on for forming the image.

From this it appears Mr. Ives makes no claim for fish glue, nor do I believe either Mr. Levy or Mr. Wolfe, both of whose processes are understood to be on the gum basis. Either Hyslop or Heimbecker have a better claim, but I cannot say whether either were originators of the fish glue or that they only took it up after the secret leaked out. Certainly they both exploited fish glue, and their names are the only ones I have publicly heard of. Hyslop placed an "enamel" on the market, which I have tried, and do not think is anything else but a clarified fish glue, though it is essentially different in appearance to the Le Page's Clarified Fish Glue. He eventually published his formula. Heimbecker never owned up to the use of fish glue, though the stuff he supplied for the use of those who paid him for the formula was very suspiciously like it. His process was eventually exploded by one of his pupils publishing it in an American trade journal. It was the well-known formula of 2 ounces of glue, 2 whites of eggs, 4 ounces of water, and 120 grains of ammonium bichromate. About that time every half-tone worker appeared to have a secret enamel process to sell, and many were sold. This applied both to the process and to the people who bought it in many cases. I heard of one amusing case in which two operators each had an enamel process, which neither of them could work, though neither would admit it. They each believed that, if the two formulæ were compared, they would reveal something which was wanting on both sides, and eventually they agreed to exchange formulæ, upon which it turned out that both had the same thing, and both had evidently derived it from the same source viz., some trade journal.

In spite of these supposititious processes, there were on the market then, and for a year or two previous to any publication of an enamel process, some practical formulæ offered for sale by makers of screens and dealers in process appliances, and many firms, both in America and in this country, derived their earliest knowledge of the enamel process from these sources. It was found that it was not so much the formula as the manner of working it that was the valuable part of the secret, and here was where the vendors of the processes scored over the professed formulæ that were published. Many who had tried the published formulæ, and could not work them, eventually bought the instructions. The process, in fact, depended a good deal upon experience or practice, the method being so novel that operators could not be induced to shake off the habits of working and adapt themselves to the new conditions. Most of the successful enamel workers of the present day can look back on some disheartening early struggles to master the tricks of the process. They had to find out how to meet the varying viscidity and tenacity of the glue, the conditions of climatic changes, the values of bichromate in the solution, the suitability of the negative, the best methods of coating and drying, the extent to which to carry the burning in, the best method of etching, and a hundred other little things which go to make the success of the process. A great many of these points could hardly be imparted in written or printed instructions. They are just the sort of things which can only be picked up by seeing a practical man at work day by day meeting all the little difficulties as they cropped up.

Of formulæ there have been, I was going to say, hundreds published, but they hardly run to that extent. Yet the *Photographische Correspondenz*, a few months ago, tabulated comparatively twenty-four different ones, collected from various sources, and Cronenberg, in his recently published book, *Half-tone on the American Basis*, gives seven distinct formulæ. It must be seen when compared in this way that they all bear a strong family likeness. In the *Photographische Correspondenz* batch fifteen out of the twenty-four contain ordinary fish glue, three give clarified glue, and the remainder introduce a little variety with albumen (dried or fresh), gum arabic, gelatine, Cologne glue, and white glue. Sixteen formulæ give fresh egg albumen in addition to the glue, whilst only one gives albumen alone. Three give gum in addition to glue or albumen. Twenty-one formulæ out of twenty-four contain ammonium bichromate in preference to the potassium salt.

Taking the first twelve fish-glue formulæ, I find the average components to be about as follows:—

Fish glue (ordinary)	500 parts.
Egg albumen	400 „
Ammonium bichromate	37 „
Water	1000 „

This comes to pretty much the same thing as the practical formulæ in general use. There is no standard formula, because a standard would be impossible when it is well known that the glue varies in viscidity, and that sometimes it will take a larger proportion of bichromate than at other times.

A typical formula for the gum process is the following, published in 1893 along with perhaps the first fish-glue formula seen in print:—

Gum arabic (finest)	1 ounce.
Saturated sol. bichromate of ammonia	1 „
Chromic acid	10 grains.
Water	10 ounces.

The glue formula given was:—

Glue	2 ounces.
Eggs (whites)	2 „
Water	4 „
Bichromate of ammonia	120 grains.

These were published in the American *Artist Printer*, and have been extensively copied therefrom by various publications.

A modification introduced by A. C. Austin, under the title of the Adamantine Process, consisted simply of introducing well-ground lamp-black into the bichromate fish-glue solution. Others have introduced aniline dye into the solution, but this did not improve the printing quality, and it washed out before development was complete The best way has always been to stain the image with the aniline dye in the course of development.

It may be mentioned that the gum process has never been considered suitable for zinc etching, on account of the high temperature required for fully burning in the enamel. On copper it goes very well, but it is more difficult to manage in many ways than fish glue. It may be doubted whether the enamel process at its best is suitable for zinc. The intense heating changes the character of the zinc, making it soft and coarsely granular, but it is worked, nevertheless, by many on this metal.

The whole subject of these enamel processes is exceedingly interesting at the present moment, and there is a great amount of scattered information on the subject which would be valuable if brought to a focus. I hope to make some further points the subject of a subsequent article in these pages. WILLIAM GAMBLE.

MECHANICAL AIDS IN PRINT-WASHING.

I AM glad to notice, in the report of a recent meeting of the London and Provincial Photographic Association that Professor Stebbing has drawn attention to the method of print-washing that I described in an article on page 581 of last year's volume, and I am only sur-

prised that its simplicity and efficiency have not brought it into more general use. If reiteration of its good points will have any effect in bringing it into use, that must be my excuse for once more directing attention to it at a time of year when *rapid* and thorough washing are of the very highest importance.

All users of gelatino-chloride and collodio-chloride papers must be too well aware of the fact that these will not bear with impunity the same amount of rough usage that is permissible with albumen, although it is at least equally necessary to remove all soluble matter from them. Prolonged soaking in still water, with the prints massed together in contact, is worse than useless, and the old-fashioned style of mechanical washers is scarcely safe with the extremely tender modern films. The only course open for adoption is therefore the plan usually followed, of changing the prints singly from one vessel of water to another, and this necessarily involves constant attention, or practically so, during the whole period of washing, for, as soon as that attention is taken off, the prints settle down in contact with one another, and the process of diffusion, to all intents and purposes, ceases.

But under proper conditions, where diffusion can proceed freely, simple soaking in even perfectly still water, changed at intervals, is in every way as effective as the most violent *frictional* washing; indeed, it is better, for, no matter how powerful a stream of water may be directed on to the prints, it has little effect beyond cleaning the surface, the salts contained in the body of the paper, and in the sensitive films, being only removed by gradual diffusion. The simple apparatus described by Professor Stebbing and myself provides the necessary conditions, by keeping the prints rigidly separate, and at the same time permits the water to be either gradually and constantly changed, or the tank to be completely emptied and refilled instantly at intervals, without the necessity for handling each individual print.

All that is required is a tank or vessel somewhat deeper than the ordinary "deep" porcelain dishes; the washing tanks used for negatives will answer perfectly, but I prefer a deep wooden tray built up of ordinary flooring boards, which, with a very ordinary amount of care and ingenuity, can be made perfectly watertight. This has the advantage that, for a few pence, a tray of large dimensions can be made to accommodate trays which will each hold several prints, and so save the necessity for constructing a large number of individual trays. For the rest, these trays consist of light frames of wood, not necessarily more than a quarter or three-eighths of an inch deep, over which is stretched some sort of netting or open fabric, to convert them into a sort of sieve. A friend of my own uses strips of light cane, fastened together at the corners, Oxford frame fashion, and strung across after the manner of a tennis racquet, with stout ordinary thread. If of large size, these frames may be subdivided into separate cells for each single print; a frame measuring fourteen or fifteen inches square will then hold half a dozen half-plate prints.

In use the frames are filled with prints and piled one on top of another in the washing tank with a weight of some sort to prevent them floating up. The tank is then filled with water, and the prints left to soak, each one being freely exposed on both sides to the full action of the water. The tank may be provided with a syphon or overflow pipe to allow of a continuous change of water, or it may be emptied bodily at intervals by simply lifting out the whole block of trays and refilling, this plan ensuring a thorough and complete change of water. A very slight movement or agitation of the block of trays will set the water in motion over the whole surface of the prints, both back and front, and, in fact, the washing proceeds in the most thorough manner possible with a minimum of attention.

Professor Stebbing speaks of the prints being thoroughly washed with a very small quantity of water if left all night; but, though I do not say this is an injurious length of soaking, it is not desirable at the present season with gelatino-chloride paper, especially if unalumed. Practically I find an hour with a gradually changing current of water, or six or eight changes bodily, at intervals of a few minutes, will effectually remove all soluble salts, and during very hot weather I think it is indisputable that rapid washing, if thorough, is in every way desirable. W. B. Bolton.

DYES AND PIGMENTS IN PRACTICAL PHOTOGRAPHY.

II.

2. *Pigments for Carbon Tissue.*—Pigments for the carbon process require special qualities in addition to the usual considerations of permanency. Being themselves chemical compounds with specific reactions, we have to consider their behaviour in the presence of potassium bichromate, and with the gelatine or other colloid medium employed. Of secondary, but by no means of small, importance is the degree of cohesion of the particles when the pigment is finely powdered and mixed with gelatine, and their consequent freedom from any tendency to agglomerate, instead of remaining evenly distributed through the film. This granulation is an insuperable objection to the use of certain pigments, which would otherwise be of service. The use of ordinary lamp-black, for example, has for this reason been abandoned by many workers in favour of Indian ink.

Great care must be taken not to use any pigment containing fatty matters, even in a minute degree, as these tend to form insoluble substances with gelatine and potassium bichromate. Ordinary lamp-black must, therefore, be purified from any greasy matter by washing first in benzole, and afterwards in a strong solution of potash or ammonia. Some pigments produce this insolubility of bichromated gelatine, even when pure, as, for example, the mercury compounds and many of the lakes containing a base of alumina or zinc.

The cold, black tone of pure carbon is changed to a disagreeable tint by admixture with the green alteration product of potassium bichromate. It is, therefore, necessary to add to the black some warm pigment to neutralise this effect. In the early days of the carbon process, both carmine and cochineal were used for this purpose, the fugitive character of which pigments greatly imperilled the reputation of the carbon process for permanency, since it was found that the rich, warm, photographic black thus obtained speedily relapsed into a greenish-black mixture of carbon and chromic oxide. The substitution of alizarine for carmine speedily overcame this defect, which is also obviated by Monckhoven's suggestion to use for admixture with carbon the ferric oxide precipitated in a spongy state from a ferric chloride solution. The greenish colour of the chromic oxide produced in carbon tissue becomes of still greater consequence when delicate shades of mauve or rose madder are used as pigments. For this reason it is necessary, when using these colours, to add as little bichromate as possible, and to make up for the deficiency by more prolonged exposure.

The use of the madder lakes also is not unattended with difficulty, for the permanency of this pigment seems to depend, to some extent, on the amount of alumina used to precipitate the lake; but, if enough alumina is added to ensure permanency, the pigment reacts upon the bichromated gelatine, rendering it insoluble.

This difficulty has been overcome by adding, in the first place, only just enough alumina to precipitate the lake, and then substituting another base, such as a salt of lime or magnesia, in sufficient quantity to make the colour permanent. To secure the best results, therefore, special precautions have to be taken in the preparation of lakes, some of which are found to be too soluble, and liable to stain the collodion in the single-transfer process, or else to dissolve out in the alum bath.

When using enamel papers in the carbon process, the enamel pigment should consist of some inert substance, such as kaolin; for zinc oxide, barium sulphate, and lead carbonate, are all liable to become stained by double decomposition with the bichromate.

It is often useful to employ double-tinted films for carbon work, the upper stratum containing sepia, and the lower one purple. By single transfer the films are reversed, and an image in sepia on a purple ground is produced. By this means a greater depth of tone is to be obtained than when a single colour is used. Landscapes should be in two colours of a somewhat similar nature, such as dark brown and sepia, or purple and violet. Mountainous scenes may have a lower shade of dark sepia and an upper layer of blue. By having a warm, thin, brown tone on top, and a very dark tone below, we get, not only delicate half-tones, but deep black shadows in addition.

A wide range of colours is available for the manufacture of pigmented carbon tissue, and it is possible, in many cases, to reproduce works of art in the original monochrome in which they were drawn. This is especially the case with red chalk drawings, pencil sketches, and wash drawings in Indian ink or sepia. Unfortunately, there is a very great variation in the proportion of colouring matter in commercial samples of the various pigments, and consequently great discrepancies exist in the various formulæ which have been proposed for the production of different tones. These discrepancies

are easily intolligible when it is considered that the proportion of carbon in different samples of Indian ink has been found to vary between twenty and sixty per cent. The following tables, therefore, must be regarded as giving only approximate quantities in grammes per kilogramme of gelatine:—

	Reddish-brown Tones.			Photo-tones (Purple).		Red Chalk.	Dark Brown.
Lamp-black ...	6	5	5	—	—	—	—
Indian ink ...	—	—	—	4	3	4	—
Bone black ...	—	—	—	4	3	—	15
Burnt sienna ...	12	10	15	—	—	3	—
Raw sienna ...	4	—	5	—	—	—	—
Purpurin ...	8	—	10	—	—	—	—
Prussian blue	0·5	5	0·5	—	—	—	—
Alizarine ...	—	10	—	—	—	—	—
Rose madder ...	—	—	—	3	3	—	—
Indian red ...	—	—	—	5	—	—	—
English red ...	—	—	—	—	—	2	3
Vandyke brown	—	—	—	—	—	—	2
Indigo	—	—	—	—	—	—	1

With regard to the purity of these pigments and their reaction with each other, inferior samples often lead to troubles. *Lamp-black* often contains a large quantity of ammonia, and Indian inks may be adulterated with earthy impurities. Both *Indian red* and *English red*, as now frequently prepared, contain a trace of sulphuric acid sufficient to destroy other colours such as indigo. Both *Vandyke brown* and *sepia* have recently been proved to be somewhat wanting in stability, and Professor Church has shown that a year's exposure to sunshine causes an appreciable change in colour even of the *madders*. *Prussian blue* and *indigo* are liable to oxidation by the bichromate.

To prepare the colours, it is necessary to grind them very fine on a slab with a muller, and make into a paste with a little gelatine to ensure perfect admixture with the main quantity of gelatine. For transparencies even greater care in grinding is necessary, and the pigmented gelatine must be filtered before using. Since the finest state of subdivision is necessary, it is not safe to use powdered pigments which have been kept long, on account of their tendency to aggregation. If required to be kept, it is better to mix them up with a little gelatine and let them set and dry completely, after which they can at any time be redissolved for use without the risk of agglomeration.

Ceramic Pigments.—The action of heat in the process of firing enamels precludes the use not only of organic colouring matters, which would carbonise, but also of those mineral pigments which are altered in tone at high temperatures, such as viridian, the hydrated oxide of chromium (which loses its water of hydration on heating), and volatile pigments like vermilion.

Obernetter has shown that the quality of the colour is liable to be affected by the action of potassium bichromate. This is especially noticeable when lead fluxes are used, yellow lead chromate being formed, and the resulting colour of the enamel modified in consequence. As enamel pigments usually consist of metallic oxides, which are especially susceptible to the action of acids, no powder image should be washed in acids, but rather with an alkali, such as soda, which is not only harmless in its action on the colours, but also dissolves any lead chromate which may have formed.

The action of the flux is also to be considered. Certain enamel colours, notably manganese dioxide, require alkaline fluxes, such as borax, which, however, are not always suitable, as they cause some colours to run. Lead fluxes are not so suitable for such colours as gold, purple, and cobalt blue as for the darker shades produced by the oxides of iron and antimony.

Ceramic colours are usually sold with the flux already added, the underglaze colours containing less flux than overglaze colours. If the colours are prepared specially, it must be remembered that the different oxides have different fusing points, and that the proportion of flux must be varied accordingly. If the carbon process is used for the production of the enamel, the proportion of gelatine must be increased sufficiently to hold the heavier pigments in suspension. Sometimes a little carbonaceous matter is beneficial to prevent peroxidation of protoxide colours, with a consequent loss of colour. This is especially the case with the red oxide of copper, but any carbonaceous matter is to be avoided with peroxide colours, on account of the danger of reduction to a lower degree of oxidation.

The following are the pigments recommended for the various enamel colours:—

Black.—Protoxide of iron, or manganese dioxide, with a trace of cobalt oxide, a mixture of equal parts of copper oxide, cobalt oxide, and manganese dioxide may be used.

Brown.—As above, using oxide of antimony in place of cobalt.

Purple.—Oxide of gold and manganese dioxide.

Blue.—Oxide of cobalt either alone or toned down with zinc oxide.

Yellow.—Antimoniate of lead (Naples yellow).

Green.—Chromic oxide and oxides of copper and cobalt.

Violet.—Manganese dioxide and purple of cassius.

Orange.—Red oxide of iron and oxide of antimony.

Red.—Protoxide of copper.

White.—Oxide of tin.

The flux for the ground of the enamel may be coloured in imitation of various gems by suitable admixtures of the above substances. The process of firing converts the metallic oxides into corresponding silicates. The composition of the two typical forms of flux is as follows:—

1. White Enamel.

Lead oxide	10 parts.
Tin oxide	3 „
Powdered quartz	10 „
Common salt	2 „

2. Transparent Flux or Strass.

Powdered quartz	1600 grains.
Borax	560 „
White lead	3200 „
Manganese dioxide	1 grain.

J. Vincent Elsden.

OUTSIDE STUDIO WORK.

II.

In a previous article reference was made to the great difference that existed between operating inside a studio and the all-round working of an outside operator, who has to undertake at times subjects requiring special apparatus for his work. To attempt to detail even a small portion of what may be termed special jobs of this kind would indeed be difficult. Mention, however, may be made of those subjects which require the camera being held in a vertical position; in this class we find ancient gravestones bearing inscriptions; these are often required to be photographed by antiquarians and others for the purpose of book illustrations. In work of this kind an ordinary tripod is of no use whatever unless the subject be of very small dimensions; and when such has to be undertaken, special staging must be employed, whereby the camera can be elevated to the required height and placed in a suitable position, the lens pointing downwards. To permit this being done with any degree of comfort or security, specially arranged clamping boards to carry the camera should be provided; these are two boards joined at one side by strong hinges having an eyelet in one of them, through which the camera screw passes to bind the camera; at the downmost end of this is placed a ledge of wood about three inches broad, this acts as an extra support for the front of the camera to rest upon, and relieves the extra strain thrown upon the binding screw of the camera. When such is used in this upright position, guy rods or laths are then nailed temporarily from the upright board, carrying the camera to the sides of the baseboard, resting flat on the staging, to enable which being kept absolutely steady, the service of a fifty-six pound weight will be found about as handy as anything to employ if it can be easily procured; if not, a good heavy weight of some description or other must be substituted; to balance the weight of the camera, some heavy stones are useful when more handy articles are not forthcoming.

Once an operator has so arranged his staging and a support or tripod for his camera, whereby such can be made to point downwards, he has overcome the chief difficulties in this work when such has to be performed in the open air; alas, however, such jobs have sometimes to be undertaken in interior situations where the light is very bad, in fact, quite unsuitable for photography unless recourse be had to some means of artificial lighting.

I remember one instance where the difficulties in lighting a very old tombstone were so great, that several experiments had to to be made both with slow combustion powder and also the use of lime-light jets; eventually satisfactory results were obtained by burning a plentiful supply of magnesium ribbon at several points to the side and above the camera.

I find that, as a rule, antiquarians are very particular about the correct representation of every figure or inscription such tombstones contain, hence the need for a careful preparation of the stone before

hand. I strongly advise any one having such a commission to undertake to make it distinctly understood that such cleaning, or clearing away of the dirt and rubbish of years, is in no way the duty of the photographer, but is entirely devolving on those who desire the work being performed.

To enable this being done properly is by no means so easy as many might imagine, and in some instances means a deal of bother to get even permission to lay a finger on such stones; for instance, special permission even to photograph inside our Glasgow Cathedral has to be obtained from the Commissioners of Woods and Forests in Edinburgh. Antiquarians, however, never object to spare any amount of trouble in endeavouring to decipher the most minute letterings or marks, and the services of a competent mason are nearly always required; this relieves the photographer of a large amount of risk and trouble, and should be always specially agreed upon when terms are being arranged.

When such tombstones are situated in the open air, then the work is not nearly so difficult of execution, and generally resolves into the erection of suitable fixings and the selection of the best time of day for exposure; the best result I ever saw obtained was late in the evening, when the shadows were long and low. It is wonderful what a lens and a sensitive plate will bring into view in work of this kind. I have known instances where very important detail has been divulged that was of the utmost importance to the antiquarian, and from which some very interesting deductions were made that were never thought of previously.

At the present time a heated discussion is going on between some learned gentlemen as to the burial place of one of our ancient Scottish kings, and photography has lent valuable aid in deciphering an almost obliterated inscription, upon which much depends in the way of settling a very crucial point in the argument.

The using of a camera in a vertical position to photograph numerous small objects has recently been brought prominently before the public by means of a description of a useful piece of apparatus that is now upon the market for serious outside work of the kind I have described; however, all tripods are simply useless, there is nothing better than a couple of good tressels with stout plankings thrown over them, and the flap to carry the camera as I have described.

T. N. Armstrong.

OBSERVATIONS ON PICTURE-MAKING.*

It must not be thought, however, that unity of subject can only be expressed by the singleness and isolation of the chief elements, as in the case of the mills we saw. We may have groups and masses acting as the prominent features of a scene, and these may perhaps extend over a larger portion of the area, as in the case of battle pictures. Unity of subject is really very much a mental matter and amounts to very much the same thing as unity of idea. In this reproduction of *The Lion Hunt*, by Rubens, there is no one figure that is more pronounced than another, unless, indeed, it be the warrior in the centre who is about to strike the lion with his sword. There are seven men and six animals; but only one idea—the capture and slaughter of the lion. The ground, the distance, and the sky are quite unimportant, the picture being entirely filled with the motive, which finds expression in the bustle and confusion of the episode.

The principle of massing is essential to such effects as these. A composition that is scattered is in the same degree weak, and therefore not so well able to do its work.

This view of fishing boats, by Mr. Mummery, is very satisfactorily composed, because the boats are fairly well massed. If you can conceive them more apart from each other, you will find that they would "fight," as we say. By massing them, or, rather, catching the moment when they massed themselves, which is the same thing, the operator gained unity for them, and therefore strength: we are able to think of them as *boats*, rather than as *three boats*. Their lines also come very happily: their slanting booms round off the right angles formed by the masts with the hulls and lead to the row boat in tow, tying it, or holding it, so to speak, to the mass. You will notice that the boats together make a wedge-shaped form, and the waves also are at a suitable line, opposing and balancing the line of the booms.

This pretty scene is another of Mr. Wall's. The landscape composes well, but the whole suffers from a want of massing. Had the operator exposed the plate when the ferry boat was nearer the trees, under which, if I mistake not, the landing stage is placed, the whole would have gained in strength, and, as a composition, it would have been finer. The interest would then have been massed together, for the trees constitute the chief interest in the landscape, and this should have been enhanced by the boat, which, in its present position, detracts from it.

The next slide shows what is meant in a highly satisfactory way. It will be apparent to all that, although there is an abundance of points of interest in this picture, there is, nevertheless, no rivalry between them. The steamers are primary, the barges secondary, the Tower bridge and the tugs are tertiary, and the mind is content with this arrangement, which allows the eye to be carried round in a crescent-like path from one object to another in the true order of its importance. No painter could improve on the composition of this. The horizontal lines of the bridge are well borne out by the barges at each side of the picture—an arrangement which keeps the whole restful and broad, in spite of the bustle and life of the scene. This slide is also lent by Mr. Wall.

I spoke just now of a wedge-shaped form in the picture of the boats, and also of a crescent shape in this slide. It will be found that most well-massed compositions suggest some shape to the mind, and this is a distinct advantage provided that the shape is no more than merely suggested. Thus we may have crescents, wedge shapes, spirals, S shapes, pyramidical forms, and numberless others that defy all nomenclature.

We now come to a pair, by the same artist, which show an alternative arrangement of similar elements. It is extremely interesting to get in this way two different compositions of the same subject, and much more is likely to be gleaned from them. The first one shows a very agreeable composition, taking the form of what, in copy books, is called a pothook. This form starts in the tree, runs down through the group of girls, then up through the cottage, and down again to finish in the man's figure. It is all very nice, only the group and the cottage struggle for a first place, and the parts are all similar in *weight*, as we say. Here, however, is another version; to my mind a better one. The cottage, by being a larger mass, becomes undoubtedly the motive of the picture, and we feel glad to have the matter settled. There is still sufficient of the pothook composition left, and, in addition, a great gain in breadth. We have a much finer sky, and a broad foreground, giving relief and charm to the smaller and richer parts, and this foreground is just sufficiently broken by the shadows and pebbles to prevent its looking empty; moreover, although this touches another matter entirely, the group is capital in its go and happy lack of self-consciousness.

Before we leave the subject of massing we will look at two more pictures, the first by Mr. Wall and the second by Mr. Evans. They both show that a composition may be massed to any extent, and yet be neither heavy nor dense. The delicacy of these trees and the exquisite variety of colour and wealth of detail in them will commend the picture to you, and I need say nothing of the charm of the other portions.

This is Lincoln Cathedral, seen through the trees of the Vicar's close. No one would choose such a point to view the place itself, but such an object was not in the operator's mind. His was a more subtle one. You will notice that the trees and the near houses make roughly a right angle of rather strong tone, and that the towers of the Cathedral do the same in a much more delicate colour. This is a coincidence which we can forgive the artist for making actual by backing up the thin dark stems of the trees by the broad light mass of the towers, for such a treatment, besides being an agreeable bit of pleasantry, softens the trees, gives value by contrasts to the towers, and gains solidity by massing for the upper part of the picture. In this slide we can also find an example of *repetition* in the gable of the house being overtopped by the larger one of the fane; further, an example also of what, for want of a better term, I call *building up*, which is something akin to massing, but not quite the same thing. It is seen here that the mass made by the small gable and all to the right of it, supports the larger gable and its neighbouring masses, and superimposed upon this again is the tall tower; and the whole of this mass is strengthened by the trees in front, which to the right have a similar boundary of mass to complete a pyramidal form.

But this *building up* is better exemplified in the next slide, a charming view of Belaugh Church, well beloved by visitors to the Broads. From the house and the deep shadows below we have a steady and determined building up of the mass until the church tower tops it all, gaining sublimity from its position, to which all other elements in the picture perforce contribute. If only some advantage could have been taken of a variety in colour or tone in the water, or even a small boat, thus to secure interest to the lower portion and possibly break the line, the picture would have been all the finer for it, I think. Perhaps a wherry with the sail down would not have been too overpowering for the church.

Let us now give a thought or two to *balance*. The term explains itself. Perfect balance, as it appears in absolutely symmetrical designs like those of the decorator, is not desirable in landscape art; for the

* Concluded from page 426.

reason, I imagine, that such a thing never occurred in nature, except as the result of modification by artifice.

Some figure subjects have been so composed, particularly the Early Italian altar paintings, in which it was necessary to be severe, impressive, and unlicensed; but paintings of this kind, like that also of Mr. T. C. Gotch in the present Royal Academy Exhibition, though realistic in detail, are, nevertheless, quite decorative in intention and effect. Symmetry, then, we must leave to the decorator—the ornamentalist, as some call him—and the architect. Where we employ balance, it must be of that sort only which exists in the impressions of the mind, and is too subtle to submit to measure or calculation, a compensation, as much as anything, demanding that what is weak must be opposed by a smaller amount of what is strong, or *vice versâ*. If the elements of a picture are symmetrically balanced, as would be if three trees of about the same character were placed in a row, the result would be tame, for this reason: objects that are at equal distance each from the other have a minimum of relationship to each other: there is a baldness and independence in their relative positions which awakens no interest in the mind, and the inter-spaces tell with a boring monotony. Iron railings that have no redeeming ornamental work are a sufficient instance of this. A gate is better, because the parts are usually bound together or enclosed, but this trenches upon another principle. If three objects, say, stand thus each upon its own merits and tell no tale, we feel impelled to move one. In so doing we certainly make a greater estrangement from one of those remaining, but we make also a nearer approach to the third, and thus a relationship is effected which is no longer bald. There is a tale being told, and we have, moreover, a variety in the interspaces. Here is a very fine picture of Mr. Evans's which just, and only just, escapes the unhappy arrangement I allude to. It is saved, firstly, by the further beech having a smooth trunk, which makes a slight difference in the three chief items; secondly, by the middle tree having another trunk either adjoining or quite close to it, which, with the third trunk seen beyond, helps to make a *mass* of the second and third trees and what is between them. Thus the idea of *three beeches* is somewhat modified in our minds into a *group of beeches* with *one knobbly beech in front*, which is better. In the next slide by Mr. Mummery, where the lighting, foreground, balance of light and shade, and other qualities are surprisingly fine, we find the same symmetrical disposition of the trees, which, to my mind, mars an otherwise lovely thing. One cannot help looking at the trunks in a one-two-three, three-two-one sort of way. The weight of the foremost as compared with the others would be sufficient to put matters right were not the two spaces between so similar in character and tone. Perhaps a slight change in the point of view might have made all the difference. A draughtsman would probably have altered the relative positions of the trees, or placed a figure or two in one of the spaces.

Here, however, we have balance without symmetry—a marked success—two groups of upright trees, with a straggling one nearly in the centre. The two groups obey another profound law of beauty, which is *similarity with a difference*—a most valuable principle to keep in mind. The whole arrangement here is not too central. The middle tree really springs from the right-hand group and leans over to the left one, thus having a sympathy with each and uniting both—exactly what iron railings do not do for each other. This slide and the next are both by Mr. Evans, taken in the New Forest, and at last we get the best composition of all; the single tree sufficiently opposing the line of trees which runs right into the heart of the picture. There is a distinct S shape to be seen along by the roots of the line of trees. This belongs to the province of line composition, the advantages of which are, that continuity of parts is preserved, items are connected which would otherwise be patchy, and the contours and boundaries of parts can be made to express strength, vigour, grace, or movement by its help. Here, for instance, Mr. Evans has taken in the path in the foreground on purpose that it may be traced meandering throughout the whole depth of the landscape. The power and charm of the sweep which the sinuous line takes must be felt by all. Nevertheless, there is not much interest below the trees. The scene is not a wild one; if it were, there would probably be undergrowth or bracken in the foreground. The evidence of cultivation in a wide drive of this sort suggests figures, and a child sitting near the edge of the drive in the near right-hand corner in such a way as to round it off and not clash in interest with the trees would have been sufficient to improve the long line, which it is seldom well to allow to run right slick out of the picture (to use more slang). There would have been enough plain space left to give value to the tracery of the trees above, and the strength of tone in them would have thus found a suitable echo · the little figure on the grey stretch of turf.

We must now spare a moment to the composition of line as it affected by the principle of radiation Radiation is the sheet anchor of ornamental art, but it plays a large part in landscape also. Thi winter's view by your President might be called an ideal case, for it is an example of the radiation of lines of the most pronounced kind. There is a decided centre of the picture; the man's head, which is exactly upon the point of sight, all the leading lines radiate from that point; commencing with those of the figure itself, we see those of the road, the dog, the hedge, the fence, the horizon; and, finally, the branching of the trees, particularly the distant one, all follow the same law and meet at the same point. Now, the great advantage of this principle consists in the power it has of drawing the eye to the vortex or point where the radiation begins. It is of inestimable service in composition by reason of this power, and attention cannot be led away where it is employed. In the picture before us, however, one is tempted to think that the art has been a little unnecessarily enforced. At least, the fact that the meeting point of the lines is so near to the centre of the picture, that centre being the man's head, tempts us to think that the principle is too much in evidence, for the end of art is to hide art. Apart from this the picture is full of fine points. There is certainly no fear of a divided interest. The feeling in the figure of the wayfarer is particularly true and tender in sentiment, he is correct in tone and suitably forcible in colour.

By the same worker we have another slide which shows the principle in an excellent way. The centre is here to the left, in the group of figures, which, though a trifle picnicy—their own fault and the artist's misfortune—are suitably placed in the landscape, giving scale and life. It was just in this way that Turner's figures were placed to be a help to the landscape. A bird or a slender tree diagonally opposite to the figures would have supplied a subject which we now seem to wait for, crossing the radiating lines with a break and throwing back the foreground. The circular treatment suits the subject well, which is very beautiful in the delicacy of the distance, contrasted as it is with the well-massed foreground.

Mr. Wall here supplies an example of radiation in the sky at sunset. It is strange that sunset skies so often have the clouds—not the rays only—disposed in this way. There is a reason for it, of course, but to me, who know it not, it seems that the sun himself orders it so, to draw attention to his own glorious self.

Leaving now composition proper, we come to the art of black-and-white, light and shade, chiaroscuro, or whatever other name you choose to know it by. This is perhaps the quality next essential to photography. The Germans and Dutch have always been pre-eminent in this seductive art. It is the reverse of flatness; it secures relief, brightness, and vigour. By its aid we are able to receive a keen and delightful impression of nature without the aid of colour. Many and many a design has been saved by the timely insertion of a strong dark place or a bright light one, to the intense enhancement of all the other parts. Among all the photographs I have seen, I must confess that those of our absent friend, Mr. Evans, possess this quality in the greatest degree. He has himself told me that no photographer can do his best until he has learnt his black-and-white. I will show you one of his own slides, a stairway in the south-west turret of Lincoln Cathedral—a queer place for a photographer to go for a picture, you will say; but the result justifies the journey. In this picture there is a perfect gamut of tones, from the practically pure white on the step in the middle to the rich, impenetrable gloom of where the topmost step should be if the eye could distinguish it. It is here, and usually in most other cases also, as though a strip of material had been painted from white to black in gradation, and then bent round in a circle until the extremes met. And what force we get when extremes meet! how the one enhances the other, and how pearly the middle tones become by contrast! It is no only so in art, but in nature too; the highest light is set off by the deepest shade. You will see by this study how artful an artist Mr. Evans is. See how he frames in this little sparkling upright jewel by the grey walls that flank it, which do what a mount should do—relieve all portions. Observe how the moulding on the right wall tells against the distant lighter portions, and how its form is preserved thereby. See what radiation there is in the roofing, and how the arches recede in progression. What graduation of tone and balance of parts!

Here is another example of strong black-and-white by the same artist—a piece of nature's architecture; yet it almost looks as though the rose window had been touched in with mortal hands; but I don't know, and can't say. The illusion is certainly very good, and the formality of the composition is, therefore, not unpleasing. The pines are great in dignity.

In this landscape by Mr. Wall we have again the circle of graduated black-and-white joined at its extremes; a very charming picture, which all must admire. There are no empty spaces, and yet all is broad and large in style. The opportunity in black-and-white which the water offered has been seized and made the most of. Now another landscape by Mr. Evans, where the best possible moment has been waited for and secured. The parts appear richly in relief, and the maximum of character has been gained for the broken ground. The shadow in the valley is sufficient to give a topographical value to the spot, and yet preserve artistic effect. It seems to me that this is a triumph in the matter of a mass of detail in a broad shadow.

We now come to the observation of how *values* or the correct strength of the tones of different objects can be made to play their part in a scheme of black-and-white.

This charming little sea piece is to Mr. Wall's credit. The relative value of the darks in the ship and the waves seem to be well preserved; and the surface of the water, besides being admirably broken, well composed and well balanced against the ship in the strength of the darks, is, in consequence, as true a piece of illusion as we have seen to-night. Whenever, in looking at a view, we feel we are actually there, the fact is due to the correctness of the values of the tones. In taking artistic liberties with the toning and printing of a photograph, a great risk is run of falsifying the values of a landscape. The result is that, though a photograph so printed may make a more pleasing picture, it will probably be less like nature. Here is a very peculiar case of values, which I am told by Mr. Wall is absolutely correct; we see that parts of the sea are in strong light, of which we do not see the source. It is seldom that the sky is in all parts darker than the objects which reflect its light, still the effect has a grand and eerie look.

The same worker now affords us a good example of the gradation of tones by the agency of mist, a medium much resorted to by photographers both by natural means (as here) and by artificial.

In the next picture Mr. Evans has risen to feelings of the most poetic and sublime sort. The composition displays the Great Gable Mountain to the best advantage. In the cleverly treated road the dip has been discovered, and pressed into service to give the necessary variety. The whole is magnificently broad and solemnly lit.

I should now like to say a word or two upon *colour*, by which I mean, of course, the black-and-white, not the particular tint the picture takes in printing, although that may count for something. It is difficult to say exactly what I do mean. A copper-plate printer would describe it as the "fatness" of the darks. When it occurs in photographs, it is due mostly, I think, to the massing of the middle tones, and the blending of them with the darks, which gives a rich and luscious look, called by black-and-white artists "colour."

I have once or twice made special reference to foregrounds, and should like, before dismissing the subject, to show you one slide of the President's. In this everything takes its proper place and proper strength; it is quiet and poetic, yet has sufficient force for its subject; but I wish you particularly to note what a great advantage it is to get a foreground of this description, by means of which the other parts are sure to gain. If, on the other hand, a foreground is flat, and runs clear and unbroken out of the picture, as so many we have seen to-night do, there is an unfinished look about it which is much to be avoided. A lot can be done in extemporising foregrounds by sticking in the earth, or among sparse bushes or tall grass, similar growth or wild flowers brought from other parts of the neighbourhood. Of course, these must be arranged with due regard to fitness and truth, so that they do not prove objects of merriment to the botanist and the countryman.

And now, for the sake of completion, and at the risk of tiring you, I think something must be said on the subject of figures in landscape. The insertion of figures is, at times, a most desirable thing to the landscape artist. Not only do they give a life interest and make a work pictorial, not to say saleable, but they also afford the artist a modicum of control over the composition in hand, being, as they are, movable items where everything else—before a camera, at least—is fixed and uncompromising. As to figure subjects proper, I do not recommend them. Portraiture is apart from my subject, of course, though even portrait groups are doubtful successes artistically. I remember seeing a tale illustrated by photographs, where the result was stiffness and self-consciousness of the models, and very decided unpicturesqueness. But figures in landscape are legitimate accessories only, and therefore the risks and dangers of the faults we have noticed are reduced to a minimum. In the view I now put upon the screen, all will admit that the children in the foreground add a great charm and value to the scene. They are not too large, are of secondary interest, and in grouping, colour, force, and scale are all that could be wished, besides which they have a delightful spontaneity and unconsciousness. In the next slide we approach nearer to the portrait set in the landscape, which is what I consider a new field for portrait artists if they can achieve something of the style that Gainsborough employed—anything rather than a painted landscape on a background. The figure here is admirably spontaneous and full of life; the dog is capital, and the foreground is of the kind I much admire. By the same artist is the next slide, a group of children, which makes a hook-shaped composition. They are not, however, quite free from self-consciousness, nor are children ever so when told to pose, they should be caught in the act. Here are some by Mr. Wall which have been so caught. They, however, are *looking out of the picture*, as artists say, who have a golden rule that figures in action, or looking in a certain direction, should have the lesser portion of the field of the picture behind them. In the next case they may be seen so arranged, and you will agree as to the more satisfactory look of completeness thus secured. I must just point out the pleasing repetition in the shapes of the large and the small figure, and the further repetition of masses in the large and the small tree. You may think that such a triviality makes no impression on the mind, but I assure you it makes a very pleasing one. My last slide illustrating this topic shows a beautiful little composition, in which the boy, peacefully fishing, gives an enormous interest (fancy him omitted for a moment!), and yet preserves the tranquillity of the scene. The picture, albeit, exhibits a point upon which I have not yet touched. You will see that there is no "way out"—another jargon term of the studios. This has nothing to do with the closed gate; but simply means that the mid-distance is stretched across the whole field of the picture, and affords no glimpse of extreme distance, or even of sky. A spot or two of light might have been introduced at the deepest portion of the trees with an increase of interest and effect.

There now remain a few slides, which I shall show to you as exhibiting varying degrees of sharpness and softness of detail. The first is a shrine in Lincoln Cathedral, by Mr. Evans, which, in my opinion, is one of the best of the series. The shrine itself is admirably set off, the mass being well relieved, by the help of light against dark, at every point; the detail in the stonework is clear and well defined, as it should be in an architectural work of this sort, yet there is not the least feeling of hardness anywhere in the picture. Most of these beautiful results come from watching the subject under all conditions of lighting and choosing the best effect. The light, as here chosen, has given breadth, as a whole, to the shrine, while emphasising its parts and its general shape, the arch and receding portions being softened in a luscious and transparent shadow. The window, by having the light falling mostly upon its inner surface, is entirely without halation.

In this, by the President, the detail is softest of all; it comes almost near to being out of focus; but it is an effect which painters are constantly aiming at, and in texture it is delightfully velvety. Like the foregoing, it is a beautiful picture, and I am truly glad to have such good things to save until the last.

In conclusion, I will, in a few words, reiterate those salient points which the artist-photographer should keep in mind. We saw, first, that it is essential to have one prime interest in a picture, and as many others as may be, provided that they do not fight with the chief or even amongst themselves. This led us to the consideration that, whatever interest we chose, it should be massed; in fact, the more the primary and subsidiary interests are attached the better for the picture. Mr. Wall's steamers near the Tower Bridge was our best example of this.

We then discussed the advantage to be gained from a built-up method of composition, which gives stability, dignity, and impressiveness. I need only refer you to Turner's countless castles and churches set upon rocks and hills, to show how much grandeur is to be gained by this method.

We next spoke of balance, which must be without symmetry, and we learnt the golden phrase, *Similarity with a difference.*

Composition of line next claimed our attention, and we found that a design gains in continuity, or, as we say, "hangs together" by the use of a line (only seen when sought for), which may be traced out along the edges and contours of all the elements of a picture. It is similar in idea to the various shapes which masses may be made to take; but it must always be bold and determined, not wavering or of an oversweet curve. In the studies exhibited on the screen the line was actually supplied by a road or path; but the mere contour of an object is enough. I have here a magnificent "old master," by G. F. Watts. It is full of beautiful lines and convolutions. Very roughly, and not very ably, I have traced these lines, which, seen by themselves, teach a fine lesson in design.

The next important matter we noticed was black-and-white, in regard

to which we found that brilliancy, by contrast and gradation, was the result of judicious arrangement of these qualities; that high lights and deep shadows will give force when it is desirable that an object should tell strongly. We then spoke of *values* and their necessity to a realistic result; then of colour or rich tonality.

Next we instanced the use of suitable foregrounds to add to the completion or rounding off of a view; and finally we came to figures and their introduction into landscape to give scale and interest.

Throughout we saw the necessity of breaking straight and hard lines, and of helping them out by any elements at our disposal, or by trimming down the print. I imagine that most tricks of this sort are done by manipulation in the study. When this is the case, let me beg of you to see that the conditions of lighting in your inserted parts are similar to those already in the negative. Judge and calculate your scale by some other object in the same plane in which your added element is to appear. In inserting skies, see that they join the horizon without betraying their foreign origin by a bright line at the junctnre. Look to it that your clouds are the right way up, and of the proper description for the effect in hand. Notice that you do not put your luminary or bright sky at one point, while your reflection in river or sea stares out from another place above which the sky is dark. Do not put elaborate and well-lit detail on the near side of a figure which has all the light behind it. See to these and countless other little trifles that only suggest themselves in actual work, and do not be above learning a lesson or two from painters, who, in their turn, have learnt, and are still learning, so many from you.

It only remains for me to thank you for the kind and patient way in which you have listened to my remarks, and to thank those three gentlemen whose names you have heard me repeat so often to-night for their kindness in intrusting to me the beautiful examples of their art and skill which I have thus been able to put before you. F. Colin Tilney.

PHOTOGRAPHIC WORKERS AT WORK.

IX.—Messrs. Adams & Co. in Bunhill-row.

We believe we are correct in saying that there exists an impression amongst many people that Messrs. Adams & Co., whose shops in Aldersgate-street and in the Charing Cross-road are well known to photographers, are dealers in apparatus and not manufacturers of it. Such an impresssion would soon be dissipated by a visit to the firm's factory in Bunhill-row, where almost everything to be met with in their warehouses may be seen in the making.

The firm, which commenced business ten years ago in a sufficiently modest manner in Charterhouse-buildings, has grown rapidly with the growth of photography as a popular pursuit, and the works which at first occupied premises in Aldersgate-buildings, were found insufficient for the demands made upon them, which necessitated about nine months ago a move into the more spacious erection they now occupy. Here Messrs. Adams & Co. possess two large floors, the first and second, the space in which is fully taken up with the machinery and benches at which cameras, changing boxes, finders, &c., are gradually evolved from the raw material.

On entering the works the first thing to which our attention was drawn was a pile of models and experimental changing boxes of one form and another, some of patterns made only to be discarded entirely, others showing earlier stages in the history of the Adams changing box itself. Here, too, we were shown a model of a hand camera of great simplicity and compactness which it is understood will be upon the market very shortly at a price which should command for it a most popular and extensive sale. On this floor are to be seen the Adams' Ideal and Vesta cameras in various stages of completion, to each of which machinery very largely contributes. How great a saving can be effected in this direction was indicated by Mr. Adams, who picked up a piece of wood in which a groove for the thumb had to be cut. "These were first made by hand," remarks he, "a quarter of a gross were turned out by a man in four hours. The same number are now made by the machine in three minutes."

In this part of the works a number of dark tents were being made, and we expressed our surprise that a form of apparatus which was so popular, not to say indispensable, in the wet-collodion days, should still be in demand. "It is largely used abroad and on board ship," says Mr. Adams, "people feel safer as regards changing if they have one of these with them in their cabin, and we get rid of a good many through export orders."

Perhaps the most interesting department in the entire factory was that in which the leather working was carried on. Three kinds of leather are in general employment here, the first being that which covers the well-known Ideal cameras. This is an ox hide which has its pattern impressed upon it by machinery. The pattern is first obtained by hand graining on a skin, which is then sent to the electro-platers. Here it is immersed in a plating bath, and a substantial electro is made of the worked surface, this electro being subsequently mounted and pressed while hot on to the smooth surface of the leather.

A seal-skin leather is that employed on the more expensive instruments, and a very fine appearance it gives them. As an example of the way in which the cost of the material for an article runs up with an increase in its size, we were shown a half-plate twin lens hand camera, which required no less than four pounds' worth of this leather to cover it. A third kind employed here is the well-known Russian leather, which is necessary in cameras made for tropical countries, to protect the bellows from the ravages of insects who have an unconquerable objection to the odour of the musk ox which pervades it.

Up above, on the second floor of the building, is to be found the gas engine which forms the motive power for the machinery, and a room devoted to woodwork. We paused a few minutes to see the circular saws and the planing machine cutting up and smoothing wood in different forms, the last-mentioned tool revolving at a high number of revolutions a minute, casting up a column of fine shavings in the air and making a deafening noise as it gripped each plank and forced it along under the whirling knife. We were glad to escape into the comparative calm of the main building, where a large number of hands were at work on what is probably the most popular of all Messrs. Adams' productions, the Brilliant View-finder.

These were to be seen in all stages, piles of the lenses and mirrors of which it is composed, stampings in brass and aluminium for the bodies and finders being put together, or finished and packed.

On this floor is to be found the usual thermometer bulb arrangement for testing the various lenses to be supplied in the hand cameras as well as an apparatus for timing shutters. This latter consists of a large dial some four feet in diameter, black in the centre, but have at the edge a circle divided into a hundred parts. The camera, the shutter of which is to be tested is fixed up in front of this dial, and an arm which carries a bright tip, distinctly visible on the blackened surface of the dial, is steadily revolved by clockwork at the rate of one revolution per second. An exposure is then made on this subject, and the duration of this exposure is seen at a glance by the number of divisions passed by the tip of the revolving arm, which is clearly shown when the plate in the camera is developed.

In this and in other ways it will be seen that great care is used in testing and examining the various productions of the factory before they are placed upon the market. The works throughout looked healthily busy, compact, and well lit, and seem in every way well suited for the operations carried out in them. We had the advantage of Mr. Adams himself as cicerone during our visit of inspection, and for the readiness with which every operation was shown to us and its nature and methods explained we felt greatly indebted to him. Our interest in everything seen there was not lessened by the fact, that we are able to speak from personal experience of the many points of excellence of the firm's hand cameras.

The Inquirer.

*** *In this column we shall, from time to time, print questions that may be addressed to individual contributors to our pages, or such as are sent to us with the view of eliciting information from a variety of sources. We invite the co-operation of our readers in rendering this feature of the* Journal *useful and instructive.*

Cement for Glass and Paper (to "Cimex").—Here is an original, reliable, and economical recipe I have used for years to stick chemical formulæ labels on bottles, and that is, do not throw away any spoilt or overdone P.O.P. prints but cut them up to size required, simply wet them, and place gelatine side to the glass and rub down with a cloth. I will guarantee that they will not come off. The dirtier the glass the better for the purpose.—Geo. W. Valentine.

MAGNESIUM LIGHT.—J. H. asks: "Can you inform me if any photometric measurements have been made of the relative value of magnesium light as compared with average sunshine, or, I ought perhaps to say, *actinometric*, for I wish to arrive at the approximate relative exposures necessary with sunlight and magnesium respectively under certain conditions? Any information that you or any of your readers can give me I shall be very thankful for."—Can any reader help our correspondent?

IMAGE IN CHROMATE OF SILVER (to "Chromatic").—If this correspondent will treat his films with bichromate of potash, acidified with nitric acid, the image will be converted into silver chromate readily enough, but unfortunately that salt is soluble in the excess of acid, and so undergoes solution almost as rapidly as formed. If the bichromate contain only a very minute trace of nitric acid, or even none at all, the image will be slowly converted, but the colour will then not be what I infer "Chromatic" requires, but merely a dirty, yellowish brown, with none of the characteristics of chromate of silver about it. I have more than once, upon an ordinary gelatine plate, succeeded in getting a rich, red image of chromate of silver, although varying greatly in depth in different parts of the plates, but what are the conditions that rule the uncertainty I am unable to say.—SYNTAX.

SOLUTION OF IODINE.—PERPLEXED writes: "Can you or any of your readers assist me in my present difficulty? I have been in the habit of using iodine, followed by cyanide of potassium, for clearing up the lights of my lantern slides, the form in which the iodine was employed being the 'tincture' of the chemist's shop. But recently I procured some iodine in crystals, and dissolved it myself in spirits of wine, shaking up a quantity of the crystals until the spirit would take up no more. Now, although I am sure this solution is stronger than the ordinary tincture, it refuses to mix with water at all, the whole of the iodine being apparently precipitated to form a black, muddy mess. How am I to proceed?"—The reason of the behaviour described is, no doubt, the strength of the alcoholic solution, which contains far more iodine than it should do. The crystals are soluble only to the extent of about a grain in a pint of water, but the solubility is greatly increased by the presence of a soluble iodide, such as iodide of potassium.

IMAGE IN CHROMATE OF SILVER.—J. P. writes: "In reply to 'Chromatic,' the only way, I fancy, in which he will succeed in obtaining an image in chromate of silver will be by the somewhat roundabout method to be described, in which the aid of bichromated gelatine is called in. Prepare an emulsion of carbonate of silver—it is not necessary to preserve it from the light, except very strong light—spread it upon paper, and, when dry, sensitise with bichromate of potash in the same manner as carbon tissue, and, in fact, treat it in precisely the same manner as carbon tissue. Or the bichromate may be added to the emulsion before coating. In either case the carbonate of silver is converted into insoluble chromate of silver, which forms the pigment in the finished picture. If the chromate of silver be formed by the mutual reaction of silver nitrate and bichromate of potash, it will be soluble owing to the atom of acid set free on its formation. Pictures made in this manner can be converted into chloride, bromide, or iodide of silver, and reduced to the metallic state by any of the usual developers.

ALKALINE DEVELOPMENT OF WET PLATES.—WET PLATE writes as follows: "*Apropos* of the question of alkaline development or rather intensification of wet plates, raised in The Inquirer column, I may mention my experience in that direction, not recently but some years ago when the matter was first mooted, I think by Mr. W. H. Sherman, of Milwaukee. The plan, at first sight, undoubtedly appears to be the most rational method of intensifying an image produced by building up, since, without further straining the film in that direction, a greater depth of deposit is secured by the reduction of the metal that has been acted on by light. But in practice certain conditions have to be taken into consideration which do not affect *physical* intensification, and which in some measure militate against the complete success of the chemical method. In the first place, the power of intensification is directly dependent upon the amount of the light's action, and this is materially interfered with by the image first formed, which acts as a sort of screen or 'cut off' between the sensitive film and the solution which is required to act upon it. In physical intensification the action may go on entirely regardless of the original exposure, that is to say, a faint original image may be intensified up to any degree of opacity; but in any case the action of the solution is directly upon the image to be intensified. In the case of 'chemical' intensification the action is exactly proportionate to the degree of light effect, or would be but for the more or less retardent or neutralising action of the acid developer, and the intervention of a layer of metallic silver of varying thickness on those portions of the film to be intensified. In other words, the free action of the alkaline pyro or other solution employed is very materially interfered with, both chemically and mechanically, by the formation and presence of the first image developed, and the actual addition of density is very considerably less than might be expected. This can be practically demonstrated by cutting an exposed plate in halves, developing one with alkaline pyro or ferrous oxalate, and the other by the physical method, following this with intensification by means of the same form of chemical development adopted with the first half of the plate, and carrying the action to the utmost possible limit. If the two halves be now treated with nitric acid or other silver solvent in order to remove the image, it will be found that a far stronger reverse image will be left upon the plate developed by the chemical method alone, showing that the deposited image upon the other has more than appreciably interfered with the reducing action in the other case. I should like to ask if any of your readers can suggest a feasible means of overcoming this deterrent action."

Our Editorial Table.

THE RADIANT VIEW-FINDER.

Marion & Co., Soho-square, W.

THIS Finder, the construction of which is indicated by fig. 2, gives, from its nature, a very brilliant image, and therefore is sure to be much appreciated by hand-camera workers. No mirror or ground-glass screen is employed, and a totally reflected image is obtained, which, it need scarcely be said, is a condition that makes a finder, as such, the very best *sui generis*. The illustrations, given actual size, are explanatory of the manner in which the Radiant Finder is attachable to the camera, and it is also described below.

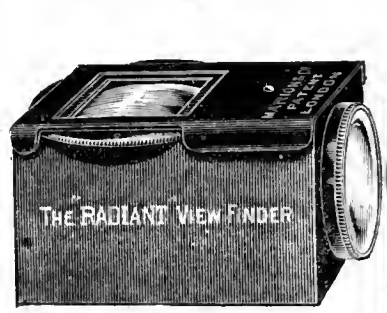

FIG. 1.

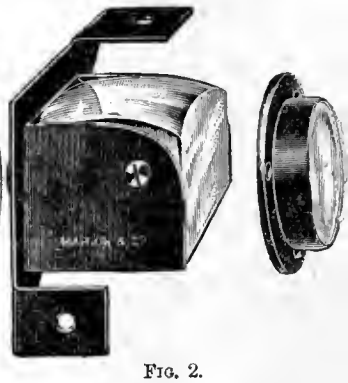

FIG. 2.

"Fig. 1 is designed for use on any camera, and is fitted with a rotating plate showing both vertical and horizontal views. In the base there are two key-hole slots for fixing to the camera by two round-head screws at top and side, placed with centres exactly one inch apart and in a line with the axis of lens.

"Fig. 2 is the form for insertion in hand cameras, one serving for both vertical and horizontal views by simply rotating it through an angle of 90°."

THE PRACTICAL PHOTOGRAPHER'S FIRST HANDBOOK.

By MATTHEW SURFACE. Bradford: Percy Lund & Co.

THIS is the ninth edition of a little work compiled for the enlightenment of novices. Mr. H. P. Robinson writes a brief but commendatory preface to the work, of which both text and illustrations are calculated to be instructive.

CATALOGUE RECEIVED.

Sands, Hunter, & Co., 20, Cranbourn-street, Leicester-square, W.C.

MESSRS. SANDS, HUNTER, & CO.'s second-hand list is devoted to the enumeration of a large stock of second-hand photographic apparatus—lenses, stand cameras, hand cameras, complete sets, and sundries in great variety.

Bruce's Matt-surface Powder.

T. S. Bruce, 6, Villas-on-Heath, The Vale, Hampstead, N.W.

Mr. Bruce, to whose retouching medium we made favourable reference some years ago, has introduced a levigated powder which retouchers, miniature painters, colourists, and black-and-white artists should find serviceable. It imparts a good tooth for retouching purposes, and is so fine that it does not scratch the film or varnish. It is also applicable to the rubbing down of prints and eulargements, cleaning ivory, the preparation of surfaces to take colour, working up, &c. We have subjected the powder to trial, and, for the many purposes for which a preparation of such extreme fineness is required, it will, no douht, prove very useful.

Beginners' Guide to Photography.

By a Fellow of the Chemical Society.

London: Perken, Son, & Rayment 99, Hatton-garden, E.C.

A new edition—the sixth—of this concise and clearly written little guide has been issued. It remains, as hitherto, an admirable handbook to present to a beginner, who will find therein simply written directions for the use of photographic apparatus which, diligently studied, should enable him to produce good photographs with hand or stand cameras; while such advanced branches of photography as stereoscopic work and photo-micrography are also touched upon.

News and Notes.

The Photographic Club.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock on Wednesday evening, July 15. Subject for discussion, *Firing Prints.* Visitors are welcome.

The London Camera Company, having taken over the premises and plant of Mr. T. Naylor, at 13, Greek-street, Soho-square, London, W., are now in a position to execute all orders for photographic apparatus of every description without delay. The London Camera Company have made considerable additions in improved plant and machinery, and will make a special feature of repairs, fittings, and alterations.

Westbourne Park Institute.—The Sixth Annual Industrial Exhibition will be held on September 21, 22, 23, 24, 25 next. Prizes are offered for Group VII., Photography.—Section A, Indoor photography, portraits, interiors, &c.; B, Outdoor photography—(1) silver prints, (2) bromides, platinotypes, &c.; C, Instantaneons; D, Enlargements (untouched); E, Lantern slides. The General Secretary is Mr. W. J. Black, 147, Shirland-road, W.

The Great Northern Railway and the Convention.—The G.N.R. are issning a circnlar giving particulars of the train service between the principal stations on and in connexion with the Great Northern system and Leeds. For the convenience of delegates (? members) who propose to reside in the neighbourhood of Leeds during the sitting of the Convention, the following arrangements for the issne of cheap tickets have been made, viz., upon production of their official passes, or letters of invitation, delegates may obtain return tickets at a single ordinary fare (minimum charge, 6*d.*) for the double journey from Leeds to any station on the Great Northern Railway not more than fifty miles distant. The tickets will be available for return on the day of issue or the following day, or from Saturday to Monday.

Directions for preparing barinm platino-cyanide, the original fluorescent substance used in Salvioni's skiascope and similar devices for directly viewing Röntgen shadow pictures, are thus given in the *National Druggist:* "It can be obtained, no donbt, of any chemical works on application, but as to its cost we have no information. It can be prepared very easily by proceeding as follows: Add 3 parts of barium carbonate, in finest snbdivision, and 2 parts of platinum chloride, to 10 parts of distilled water. Put on a water bath and heat. When the boiling point is nearly reached, add hydrocyanic acid, a little at a time, until the cessation of bubbles shows that carbonic acid and oxygen are no longer given off. The resulting barium platino-cyanide, after crystallisation, answers to the following formula—$Pt(CN)_4Ba+{}_4H_2O$."

Influence of Acetylene on Coal Consumption.—When it is considered that our coal fields are not inexhaustible, observes Dr. Frank, of Charlottenburg, the influence likely to be exerted on coal consumption by acetylene gas constitutes a subject of considerable interest. If it be admitted that ten tons of gas coal generate 2800 cubic metres (38,886 cubic feet) of lighting gas, only one-third that quantity of coal would be required to produce a ton of carbite, or 3000 cubic metres (105,949 cubic feet) of acetylene gas, having a considerably higher illuminating power than an equal quantity of ordinary lighting gas. The above figures are based upon the estimate of 2400 horse power per hour being required to produce a ton of carbite, which is now sold at 400 francs (16*l.*) per ton; but there is every reason to suppose that this price, as well as the amount of motive power, and consequently of coal, required for the production of this substance, will soon be considerably reduced. Opinions vary greatly, however, as to the yield of carbite in acetylene gas, from 225 to 350 cubic metres (mean 10,135 cubic feet) per ton being given by different authorities. Dr. Frank concludes that, although nothing definite can be predicted at present as to the final result of the struggle for supremacy by lighting gas, electricity, and acetylene, the chances are not at all unfavourable to the last-named substance.

Professor Raoul Pictet, of Geneva, lately gave a lecture at Liège on acetylene gas. During the lecture he had two candelabra, each with nine burners burning the gas, and consuming about nine and a half cubic feet per hour, little more than is consumed by a single Benzel gas burner, yet the light produced was said to be far more brilliant than the electric light. The one great drawback to the light is that, in its impure state, as prepared by the action of water on calcium carbide, the impurities present act upon metals, especially copper, and there is a liability of forming an explosive compound of acetylene and copper. Professor Pictet showed, however, that, if the gas be passed through sulphuric acid at a temperature of 50° C. below zero, the whole of these impurities are removed. If, after thus purifying, the gas is stored in nickelised cylinders and a small gasometer connected to admit of expansion, the gas can be safely used, and gives an illuminating power from fifteen to forty times that of ordinary gas. The spectrum of acetylene approaches nearly to the solar spectrum, and delicate shades of flowers, &c., are very slightly altered.

Combined Action of Light and Water in the Liberation of the Perfumes of Plants.—It is light, and not oxygen, as it has been assumed, which is the principal cause of the transformation and destruction of odorous substances, but in many cases these two agents seem to act in concert. The action of light makes itself felt in two different manners: on the one hand, it acts as a chemical power, capable of furnishing energy to all the transformations through which the odorous products pass from their elaboration to their total resinification; on the other hand, it exerts a mechanical action which plays an important part in the general life history of plants, and this property explains the mode of the periodical liberation of the perfumes of flowers. The intensity of the perfume of a flower depends on the equilibrium which is established at every hour of the day between the pressure of water in their cellules, which tends to drive outward the perfumes already elaborated contained in the epidermis, and the action of light, which combats this turgescence. The whole physiology of perfumed plants flows from this simple notion. It is thus explained why, in the countries of the East, the flowers are less odoriferous than with us: why the trees, the fruits, even the vegetables, are sometimes filled with odoriferous products more or less resinified. It is also explained why in those countries the vegetation is thorny; the vegetation in those countries has too much light and too little water.—Eugene Mesnard, in *Comptes Rendus.*

Visibility of Lights at Sea.—Special investigations have been undertaken to determine the visibility of lights at sea, by the Governments of the United States, Germany, and the Netherlands, the object being to determine the intensity of light needed to fulfil the requirements of the laws governing the rules of the road, which says that the "word visible in these rules shall mean visible on a dark night with a clear atmosphere." The result of a large number of observations by the German Committee gave as the distance at which a white light of one candle power became visible, 1·40 miles for a clear dark, I mile for a rainy one. At the Long Beech Light Station, the American experiments undertaken gave the following results in very clear weather:—A light of one candle power was plainly visible at 1 nautical mile; one of three candle power, at 3 miles; a ten candle power light was visible with a binocular at 4 miles; one of twenty-nine candles faintly at 5, and one of thirty-three candles visible without difficulty at the same distance. On a second evening, exceptionally clear, a white light of 3·2 candle power could readily be distinguished at 3 miles, one of 5·6 candle power at 4, and one of 17·2 at 5 miles. The Dutch Government experiments, conducted at Amsterdam, gave a light of one candle power visible at I nautical mile, 3·5 at 2, and sixteen at 5 miles. In the experiments with coloured lights it was found only necessary to use green, as it was conclusively proved that, if a light of that colour fulfils the required test, a red light of the same intensity will more than do so. It was found that the candle power required for a green light, to be visible at I, 2, 3, 4 miles at sea, was two, fifteen, fifty-one, and 106 respectively. The extraordinarily rapid diminution of the green light with distance, even in good observing weather, and the still more rapid decrease in rainy weather, of a character which will but slightly diminish the intensity of white light, show that it is of the utmost importance to select for the glass a shade of colour which will interfere with the intensity of the light as little as possible. The shade recommended is a clear blue-green. Yellow-green and grass-green (says a contemporary) should not be employed at all, as they become indistinguishable from white at a very short distance. For the red light a much wider range is allowable, but a coppery red is probably the best.

The Thornton-Pickard Company's Employés' Annual Picnic.—The picnic of the *employés* of the Thornton-Pickard Manufacturing Company took place on Saturday, June 27, under almost ideal conditions. The weather was pleasant and fine, but not too warm, so that getting about was quite a pleasure. The party, numbering over 200, travelled in five saloon carriages besides engaged compartments from West Timperley Station at eight a.m. to Southport, arriving there at twenty-five minutes past nine. Both dinner and tea were sumptuously served in the Temperance Institute, London-street, a building most suitably adapted for the purpose. During the day numerous places of interest were visited, including the Botanic Gardens, Hesketh Park, Kew Gardens, Winter Gardens, &c. Boating and drives were indulged in, as were also various other amusements. After tea, Mr. Sanderson (representing the counting-house staff) said it fell to his lot to have the pleasure of moving a resolution as follows:—"The *employés* of the Thornton-Pickard Manufacturing Company, their families and friends, here assembled, desire to express their appreciation of the kindness of the firm in providing this enjoyable outing." In moving this resolution Mr. Sanderson stated that the firm had most generously undertaken the whole expense connected with this picnic; not only had they paid the travelling expenses, but they had also provided both dinner and tea, and that not for the *employés* alone, but for their wives and families, whilst the single men were at liberty to invite a friend to partake of this almost unheard-of hospitality, the only stipulation in this case being that they should pay the reduced railway fare. This was only another instance showing how deep was the interest taken both by Mr. Thornton and Mr. Pickard in the welfare of those whom they employed.

During his long connexion with the firm he had had many opportunities of noticing this, and could give almost innumerable instances proving conclusively that the motto of the firm was not "Get all you can by giving as little as you can," but that, as the business increased, as it deserved to do, they let their workmen participate in the benefits of the increase. If employers generally were like theirs, there would be less recrimination and fewer bickerings between employers and employed, and strikes would also be avoided. He was sure all would return to their duties on Monday more resolved than ever to uphold the honour and the world-wide reputation of their firm. He considered it a great honour to be connected in any way with the Thornton-Pickard Manufacturing Company, and it was with the greatest pleasure he moved the resolution. This was most ably seconded by Mr. Redhouse (the works foreman), and carried with great acclamation. The party left Southport at half-past eight in the evening after a day's pure enjoyment, arriving at West Timperley at ten o'clock. It was the unanimous opinion of all that this had been one of the pleasantest days in their lives.

Patent News.

The following applications for Patents were made between June 24 and July 1, 1896:—

Shutter.—No. 13, 701. "An Improved Photographic Shutter." W. Thomson and H. Smith.

Condensing Lenses.—No. 13,865. "Improvements in or relating to Optical Condensing Lenses." W. F. Butcher and G. Harrop.

Screens or Shutters.—No. 13,895. "Improvements in Photographic Screens or Shutters." Complete specification. J. W. McDonough.

Photographic Apparatus.—No. 13,912. "Improvements in or connected with Photographic Apparatus." J. Landsing.

Cameras.—No. 13,918. "Improvements relating to Photographic Cameras." Communicated by O. Richter. A. J. Boult.

Cameras.—No. 14,018. "Improvements in Photographic Cameras." J. Gage.

Screen Kinetoscopy.—No. 14,021. "Improvements in Apparatus for Producing and Reproducing Photographic Impressions of Moving Objects." C. C. Brodbeck.

Photographic Apparatus.—No. 14,038. "Improvements in Apparatus for Use in Taking Photographs." J. F. Parsons.

Photographic Process.—No. 14,077. "A Process for Producing Photographs in Gold, Silver, or other Metals on Polished Surfaces." H. Fowler.

Drying Plates.—No. 14,150. "Improvements in Apparatus for Drying Photographic Plates and Negatives." J. H. V. Watts.

Screen Kinetoscopy.—No. 14,305. "Means and Apparatus for Photographing Periodically." W. S. Simpson.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

July.	Name of Society.	Subject.
13	North Middlesex	Demonstration on Venus Paper. Messrs. Milne & Co.
14	Ashton-under-Lyne	Excursion: Woodhead. Leader, Major Bradley.
14	Birmingham Photo. Society	Exhibition of Competition Pictures taken upon the Excursions to Sutton and Warwick during May.
14	Hackney	*Defects in Sensitive Plates and Negatives.* W. E. Debenham.
14	Oldham	Excursion: Peel Park Museum. Leader, T. Widdop.
15	Borough Polytechnic	Open Night.
15	Photographic Club	Fixing Prints.
18	Borough Polytechnic	Excursion: Northfleet.
18	Croydon Microscopical	Exc.: Oxted. Leader, W. M. Holmes.
18	Hackney	Excursion: Zoo. Leader, G. Guest.
18	Leytonstone	Excursion: Leigh. Leader, C. A. Russell.
18	Liverpool Amateur	Excursion: Chester Leader, Dr. Kenyon.
18	Oldham	Excursion: Smithills Hall. Leader, James Hall.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

July 2,—Adjourned Annual Meeting,—Mr. R. Beckett in the chair.

A number of alterations and amendments in the rules were made, and a Committee, consisting of Messrs. Beckett, Mackie, and Rapson, appointed to revise the wording of the same, but at the same time preserving the existing meanings. The alterations provide that the Recorder and Librarian have a seat on the Committee of Management as *ex-officio* members, and that the office of Treasurer may also be held by the Secretary. Rule II., laying down that the Secretary shall enter up the minutes, is now worded, "The minutes, &c., shall be entered in a book to be kept for that purpose." Provision is made that a special record of any future alteration in the rules, and of any resolution concerning the management of the Association shall be kept.

Mr. J. E. Hodd brought up for examination two dark slides and some plates which had been exposed in the same, and which, on development, exhibited, in places corresponding to the position of the hinges of the slide, a broad band, which was lighter or darker according to the period the plates were left in the slides. He suspected it was caused by the drill used in the hinges.

Mr. Wall said it appeared that, the longer the plate was left in the slide, the thinner the band, and the shorter the period the darker was the band. He contended that the action, which might be due to some emanation from the material of which the hinges were made, went on and brought about the effect of over-exposure. He had had a similar experience, and, although he had taken plates direct from the maker and put them in the slides in absolute darkness, and for varying periods, he had still got the band wherever the hinge came. He recommended coating the drill with bichromated gelatine, and exposing to light to get over the trouble.

The Hon. Secretary did not think it was due to penetration of light, but rather to some ingredient in the composition with which the slides were blacked.

Mr. H. C. Rapson showed a negative which had been developed, properly fixed, and washed for an hour in a shallow dish in running water. To dry quickly, it had been treated with methylated spirit, and when only half dry had been turned over, on which some drops of spirit ran back over the dry portions, leaving a mysterious deposit in the film, which he could not account for.

Mr. Henderson thought it a deposit of gum resin from the spirit, but

Mr. Haddon said it would all vanish by washing in water once more.

Mr. Rapson detailed some comparative experiments he had made with some developer provided by Mr. Henderson against pyro soda and velox, and passed round the results.

Mr. Wall said that, to make a critical test of the qualities of developers one against another, the conditions should be more constant than would be the case in exposing the plates one after the other, and using with each a different developer. He advised the Hurter & Driffield method.

The composition of the developer in question, which had been used with much advantage by Mr. Henderson, was given by him as follows:—

A.

Hydroquinone	120 grains.
Metol	60 ,,
Sodium sulphite	2 ounces.
Water	20 ,,

B.

Caustic soda	100 grains.
Sodium carbonate	120 ,,
Carbonate of potash	120 ,,
Water	20 ounces.

Make up with boiling water and boil afterwards. For use, mix equal parts

PHOTOGRAPHIC CLUB.

July 1,—Mr. Crofton in the chair.

Mr. Welford presented a diploma of the Erratic Club to the members.

The Rev. F. C. Lambert introduced the subject of the evening, viz.,

The Relative Merits of Different Intensifiers.

He showed a print from a number of "strips" of glass which had received a series of progressive exposures, and had been subsequently intensified by the following methods: A. Mercury, followed by ammonia; B. Mercury, followed by hypo; C. Mercury, followed by sulphite of soda; D. Mercury, redeveloped with ferrous oxalate; E. Mercury, followed by silver cyanide; F. Mercury and potassium bromide, followed by silver cyanide; G. Lead, followed by ammonia sulphide; H. Cadmium bromide and silver nitrate; J. Iodine and Schlippe's salt; and K. Potassium bichromate, and redevelopment with hydroquinone. The prints from these intensified slips, when compared with the unintensified negative, showed considerable variations of scale, and Mr. Lambert invited opinions upon the results. As compared with the standard print, the slips intensified by B and C showed little difference in scale, but E, F, D, M, and K all showed an apparently steeper gradation. G was unprintable owing to the intensity of the whole deposit.

Mr. Fry asked if the intensification had been carried as far as it would go? Answer: Yes.

Mr. Mackie said that one of the things photographers often failed to remember was that it was only possible to get printable densities within certain limits. Assuming that every good negative had a certain amount of clear glass as shadow, the examples which Mr. Lambert had shown clearly indicated the amount of density which could not be exceeded without having some portions of the negative which were of no printing value. The strips marked K and M practically showed every gradation from white to black, and would, therefore, serve as guides to indicate the greatest possible density of a useful character, which such a paper as that used for printing by Mr. Lambert would render effectively.

Mr. Lambert objected that, from an artistic point of view, he did not like any clear glass on a negative, but a member facetiously remarked that the artistic argument could not be used there.

Mr. Foxlee said that Adam Salomon—who was celebrated in a previous decade for what was popularly known as Rembrandt effect—always started from bare glass—such bare glass as was only obtainable with collodion plates—and ran up the whole scale of gradation to opacity.

Mr. Fry doubted whether those characteristics which were known as "quality" and "colour" in a print could best be obtained from a negative which started from clear glass. He was speaking of the gelatine process. A negative required to possess a certain amount of resistance to the passage of light to produce the best technical effects.

Mr. Mackie contended that it made no practical difference whether the negative started from clear glass or from a slight deposit.

Mr. FRY said it would make a great difference of intensification were it to be resorted to. If the negative had clear glass shadows, intensification would always increase the contrast.

Mr. CADETT said that Messrs. Hurter & Driffield had stated that all the deposits in a perfect negative should be in the period of correct exposure, and that the representation of a black surface in a strong light should be represented by a slight deposit in the negative, and not by clear glass. He added that the fact was that our negatives were capable of representing a much longer scale than any printing paper would register, and that it was therefore always necessary to bear in mind the fact that the scale must be compressed, so far as the negative was concerned. The value of the light reflected from such surfaces as black velvet and white paper in diffused daylight was approximately as one to 300, whereas the light reflected from the deepest black in a platinum print, as compared with that reflected from the paper itself, had the ratio of one to thirty-five, and that was all that could be got from a negative, however much longer the scale of the plate might be. Glossy-surfaced paper possessed the power of rendering a more extended scale, and in that sense gave better pictures. Many artists, however, preferred the matt surfaces.

Mr. NESBIT stated that the wide range of contrast which had been alluded to seldom existed in such scenes as one desired to photograph. When it did exist, it was seldom attractive.

Mr. Lambert was thanked for introducing the subject, and the meeting closed.

Croydon Camera Club.—An excursion of sustained and keen interest was held on Wednesday, the 1st inst., by the Croydon Camera-Club, when a party of twenty-three members, in charge of Mr. Hector Maclean (the President), visited the palatial Elizabethan mansion, Hatfield House, where, by the great kindness of the Marquis of Salisbury, every facility was given the members to photograph all parts of the stately interior possessing general interest, and also to take some of the innumerable views of pictorial quality obtainable in the private gardens of this edifice, so full of interest both in regard to its connexion with the history of the Cecils and with the annals of our country since Henry VIII. This last worthy it was who first rescued Hatfield House from the comparative oblivion of an archiepiscopal palace. Had it remained in possession of the Church, it is more than likely that "Old Noll's" Roundheads would have made short work of it. Nothing at Hatfield is perhaps more impressive to the multitude than a touching memento of a great beauty and her ever-illustrious daughter—I mean a quaintly carved oaken cradle, on which are carved "A. R.," the initials of her whose fate it was

> —— "To be perk'd up in glistering grief
> And wear a golden sorrow."

This, the bassinette in which Anne Boleyn rocked Queen Elizabeth, is surely irresistible in arresting the attention and awakening the imagination of even the humblest visitor. There are also shown the trappings which the white palfrey of Good Queen Bess was harnessed with when Her Majesty reviewed her troops at Tilbury. But these are sceptically regarded, inasmuch as some historians now declare that, the appointed day being wet, the Queen did not turn out, but, local reporters having written full descriptive accounts of the proceedings in anticipation of the event, these were duly published, and hence passed into history! Happily our present age is much more conscientious, so that we can hardly imagine such things happening—no, not even in halfpenny newspapers. One thing specially grateful to the camerists was the information imparted to them that the modern and the finest portion of the mansion, which is between three and four hundred years old, is entirely the work of amateurs. If amateurs can be so supremely successful in architecture, why not in photography? This question the party put to practical test by attempting between three and four hundred views of the house and its demesne, and we have no doubt but that when, later in the year, those pleasant lantern shows are resumed at the Braithwaite Hall, a perfectly satisfactory answer will be given to the above question in the form of a brilliant series of pictures. To epitomise all the glories in art, architecture, decoration, antiquarianism, and floriculture which abound is here out of the question; enough that such imposing apartments as the famous marble dining hall, with its magnificent woodwork, and emblems of victory in the shape of Napoleonic eagle-headed banners; the long gallery, with its gilt ceiling; the armoury, with its grilled windows; the private chapel, with its full-coloured Flemish stained glass; the grand staircase, the state drawing-room, literally crammed with objects which are connected with the great people of the present century; the state bedrooms, and many more of the like, supplied more subject-matter than could be digested by even twenty cameras. The exterior views were not less entrancing, although not in all cases so suitable for photographic picturing. A word or two of praise should not be wanting for the, in many ways, charming gardens, specially delightful being the linden arcades, which form a quadrangle, in the centre of which is a most captivating pleasaunce of old English perennials, which, on Wednesday, was notable for the great masses of Oxford and Cambridge blue larkspurs, which dominated all the other floral delights. At the termination of a long day's work, the party partook of an excellent repast at the Red Lion. At the instance of the President, an enthusiastic vote of thanks was accorded to the Marquis of Salisbury for the privilege accorded to members; and, on the proposal of Mr. Underhill, seconded by Mr. Woodcock, the members' thanks were bestowed upon the President for having arranged such a notable outing. It should be added, that much of the comfort of the party was due to the admirable arrangements made as regard cheap tickets, train service, &c., by the Hon. Secretary (Mr. H. E. Holland).

North Middlesex Photographic Society.—June 30, Mr. Cox in the chair.—Mr. H. Stuart showed some carbon prints with which he had experienced some difficulty in stripping from the supports. Other members had experienced the same result, and it was put down to the hot weather. Mr. Cox showed specimens of pyramidal grain paper, which he had found gave pleasing results if sensitised either by Mr. Moss's process or plain salted silver process. He also exhibited prints on plain salted paper and a print on Kallitype paper (1891), which had not lost in intensity, and a silver print made in 1865, in which the image had not faded, although the paper and mount had slightly yellowed. The sel-d'or bath had been used in toning it. Mr. Cox called attention to an excellent article on mildew in drawing paper by Professor Russell (*Magazine of Art*, January, 1896). Messrs. Marion & Co. kindly forwarded some samples of ingenious novelties they had introduced, including the "S. B." printing frame with side clips, obviating the shifting of the print while examining; a film carrier of vulcanite, coated with an adhesive substance; and pieces of "Sweetheart" adhesive cloth for mounting prints.

JULY 6, Mr. Mattocks in the chair.—Mr. SMITH, in reporting on the outing to London Colney, said a very enjoyable afternoon was spent, a conveyance having been ordered to carry them to their destination. A number of plates were exposed, but the wind was too high for good work to be done. Mr. MUMMERY announced that Mr. Tilney's paper would be found printed *in extenso* in THE BRITISH JOURNAL OF PHOTOGRAPHY. The old question about cheap railway fares for photographers was discussed at length, the opinion being that the railway companies would not take any steps in the matter. Mr. MATTOCKS read a paper by the Rev. T. Perkins, M.A., entitled—

CRITICISM OF PAINTINGS AND PHOTOGRAPHS,

and a discussion ensued. Voting on the prints taken at the outing to Purfleet resulted in Mr. Smith being placed first and Mr. MacIntosh second.

Correspondence.

☞ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

AN IMPORTANT DISCOVERY.

To the EDITORS.

GENTLEMEN,—I have pleasure in announcing that I have made what I consider a most interesting discovery, photographically speaking, second only to the X rays, and most likely these mysterious rays have something to do with the phenomenon. I intend bringing the matter before the London and Provincial Photographic Association on the Thursday following the Convention meeting.—I am, yours, &c.,

277, *Lewisham High-road, July* 6, 1896. A. L. HENDERSON.

MOVING PICTURES ON THE SCREEN.

To the EDITORS.

GENTLEMEN,—My attention has been drawn to your remarks under the head of *Lantern Mems* in your issue of July 3, and I would like to correct them as far as they apply to me and to my patents for taking and projecting the so-called animated photographs upon a screen.

On June 21, 1889 (which, you will notice, is two months before Croft's application), I applied with another for provisional protection for an apparatus for taking photographs in rapid series. The patent was sealed on May 10, 1890, No. 10,131. A careful search has failed to find anything on similar lines prior to this, so that you will see I am absolutely the first in the field, and the pictures that are now being taken for projection, as well as for the kinetoscope, are really taken in the way described in this patent.

Now, with regard to the projection. I applied November 29, 1893, for provisional protection for an apparatus for doing this, and it was sealed on November 29, 1894, No. 22,954, so that here again I am *undoubtedly the first*. I do not often ventilate my grievances, but I do think it necessary to place these facts before you. Will you be good enough to verify them; and, after you have done so, I have no doubt you will give as much publicity to them as you have done to the statements I wish to correct.

You go on to say I am netting about 120*l.* a week from the use of my apparatus. I only wish it were true. Unfortunately it has been my fate to sow while others reap. I can safely say that my experiments in connexion with these patents cost me over 1000*l.* in money, and no end of time, while hitherto I have had no return.

I am hoping, however, that the wheel of fortune is about to turn in my direction. If it does, I shall surely take immediate and active steps to vindicate my position.—I am, yours, &c., W. FRIESE-GREENE.

39, *King's-road, Chelsea, S.W., July* 6, 1896.

[The remarks Mr. Friese-Greene attributes to ourselves were made, we must point out, by our contributor, Mr. G. R. Baker, and the reference to the 120*l.* per week was probably not intended to apply to him. However, we ourselves, so far as we can judge of the matter, are persuaded that Mr. Friese-Greene's claims to priority in the devising of apparatus for taking and projecting "animated" photographs are well founded, and we should be very pleased to hear that his great ingenuity and hard work had resulted in the reward both unquestionably merit.—EDS.]

"PHOTOGRAMS" AGAIN.

To the EDITORS.

GENTLEMEN,—Mr. H. P. Robinson's letter in the current issue of the JOURNAL causes a sense of great relief to my feelings, which were con-

siderably shocked by the report that he had adopted a word which I, and probably most other photographers of forty years' standing, decidedly object to.—I am, yours, &c., J. A. BRANFILL.

29, *Rosendale-road, West Dulwich, S.E., July* 4, 1896.

THE PHOTOGRAPHIC COPYRIGHT UNION.

To the EDITORS.

GENTLEMEN,—From the many applications received by the Committee, there appears to be some misunderstanding on the part of some country photographers that the annual subscription is still in force. Permit me, through the medium of your valuable JOURNAL, to state that this is not the case, it having been decided at the last annual meeting to discontinue the annual subscription, and that the Union should be supported by voluntary donations by the members and those interested in the welfare of the profession. To ensure membership, all that is required is the signed adherence to the rules of the Union, a copy of which I shall be pleased to forward on application to any photographer, either professional or amateur, who would like to join us and so further strengthen the hands of the Committee in their endeavours to protect photographic copyright.—I am, yours, &c., HENRY GOWER, *Secretary.*

Botolph House, Eastcheap, London, E.C., July 6, 1896.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:—

Percy Lloyd, Post Office, Albury, Guildford.—*Two photographs of his Grace the sixth Duke of Northumberland.*

HIRE OF APPARATUS.—AGNUM; C. B.; and others. See editorial note under the heading of Ex Cathedrâ.

PREMISES.—SEVENTEEN YEARS READER. Yours is entirely a case for a solicitor, whom we advise you to consult.

CINEMATOGRAPHIC APPARATUS.—WET AND DRY. Sorry we cannot help you. Better write Mr. Friese-Greene, King's-road, Chelsea, S.W.

ADDRESS WANTED.—A. URBAN says: "How and where can the *Wiener Photographische Blätter* be obtained?"—In reply: Address the publishers, Vienna.

CEMENTING LENSES.—C. TURNER. Canada balsam is supplied by all the dealers in philosophical apparatus. It is generally sold in sixpenny and shilling bottles.

BANKRUPTCY.—OPERATOR. As you are paid quarterly, your salary will be paid in full in preference to the other creditors. You are entitled to the full quarter's salary.

PLATINOTYPE INSTRUCTIONS.—SAVOIR. Our space is too limited for what you ask. Write the Platinotype Company, Charlotte-street, Bedford-square, and they, no doubt, will oblige you with the necessary information.

ISOCHROMATIC PLATES.—J. CARTER. We know of no reliable method for the purpose. Better purchase a plate already prepared. Write Messrs. Fuerst Bros., Philpot-lane, who are the agents for Lumière's plates, or Messrs. Cadett & Neall, Ashtead.

BLINDS FOR STUDIO.—R. PHILLIPS. As the sun is only on the studio for an hour or two a day during the summer months, we should not have black blinds on that side, but dark green, and of a thick material. Ordinary window holland will answer.

PATENT AND REGISTRATION.—INVENTOR. Registration would be no protection whatever in your case. You can only secure the invention to yourself by a patent. If you register the apparatus, and put it in the market, you cannot secure a valid patent for it afterwards, as you seem to surmise.

STILLS.—R. S. W. Without a licence from the Excise, it is illegal to work a still, although it is only used for distilling water. The cost of a licence is but ten shillings a year, but the licence, if taken out, will not permit you to purify methylated spirit. That is not allowable under any conditions.

COLOURING PHOTOGRAPHS.—B. MARION. The best way will be for you to get a few lessons from a proficient, and then practise and profit by the instruction given. We cannot in this column teach you to colour photographs in oil colours, or give such instruction as to be of any real service to one who, apparently, has no knowledge whatever on the subject.

RECOVERING GOLD FROM OLD TONING BATHS.—RESIDUE says: "I should be very pleased if, through your Answers to Correspondents columns, you would inform me what is the simplest and quickest way of precipitating metallic gold from old sulphocyanide and acetate baths," &c.?—If our correspondent refers to our issue of May 1 last, he will find an article on the subject.

COPYING ENGRAVING.—A BRIGHTON AMATEUR. A lens of the "rapid" type of eleven inches focus will not copy a line engraving, with fine and crisp definition to the corners, and with perfect illumination, 15×12, even with a small stop; although the same lens may, with the smallest stop, answer for a landscape of those dimensions. By all means use the eighteen-inch focus lens for the work, and hire a camera long enough to take it.

AUTOMATIC MACHINES.—J. HITCHINS writes: "Perhaps you would give me a little information. I want to get a machine in that will get the picture finished in a minute. I suppose Nievsky's patent would be the best, but I do not know where to obtain it. Perhaps you could tell me, and also give me some idea of the price."—In reply: Write Mr. L. Nievsky, 14, Granesden-road, Shepherds Bush, who, we believe, supplies such machines.

PRISMS AND MIRRORS.—PROCESS. If the two be of equal merit—that is, if each are as optically perfect, there is not much to choose between them, except that the silver surface of the mirror has to be renewed from time to time. As optical instruments, the prisms, as met with in the market, are more perfect than mirrors, and, at the same time, are more portable and are less liable to accidental injury. On the other hand, they are more costly in the first instance.

BUILDING LAW.—S. PAGE. If your neighbour's windows, although only in an outbuilding, have been in existence over twenty years, he can certainly prevent you from building a studio that will obstruct his light, and if he goes to law on the matter he will obtain an injunction to restrain, with costs, and possibly some damages. Better make terms with him, if possible. If not, find another situation for the studio, so as not to interfere with his lights.

LANTERN-SLIDE ILLUSTRATIONS TO A BOOK.—G. M. MASON says: "Will you kindly answer the following questions: Can I make life model illustrations, *i.e.*, lantern slides, to illustrate a book, without permission of the publishers of such book, and sell copies of the slides? My illustrations would be original from the text of the book, which in itself contains no illustrations."—In reply: Yes; so long as you don't pirate the copyright of any part of the book.

DIRECTORY OF PHOTOGRAPHERS.—F. W. TASSELL says: "1. Would you kindly inform me if you know the address of a firm of photographers trading as———? 2. Could you tell me if there is a directory of photographers? or can you put me in the way of finding out if there is a firm of this name, and their address?"—1. We do not know the firm. 2. Messrs. Percy Lund & Co., Bradford, publish such a book. We do not undertake to answer questions through the post.

EXPIRATION OF LEASE.—TROUBLED. At the termination of the lease the tenancy ceases, and the landlord can, of course, make his own terms for its continuance. The fact that you have worked up a good business during the seven years is nothing to him. He will make you no allowance for that when you give up possession of the premises. He can also compel you to make good all dilapidations and leave the place in good repair, even the outbuilding you put up yourself. It does not show good business tact on your part to leave the arrangement for a new lease till a couple of months of the expiration of the current one. However, you are now in the hands of the landlord, and the only advice we can give is to make the best terms you can if you desire to continue the tenancy.

MISAPPROPRIATION OF SPECIMENS.—R. M. NELSON says: "Would you be so good as to give me your advice in reference to the following: One of my assistants left my employment and opened an opposition, and in his show-case displays a copy of a group taken by me when he was in my employ. I got my solicitor to write, asking him to remove same and return it, to which I received an impertinent letter, stating he had a group, and it was lying about, and he would send it to me when he got time, and, if I wanted any more, he would do them for me. Some time ago, in your JOURNAL, I read something on this question. My solicitor is out of town, and, before he comes back, I would feel extremely obliged if you would be good enough to put me on the proper track."—In reply: If you have registered the photograph, you can proceed for damages for infringement of copyright. Better lay the case before your solicitor. See the Copyright Act in ALMANAC for 1895.

DISORDERED TONING BATH.—SOLIO writes: "1. Why does an acetate bath go black after using but two days? It is made as follows:—12 drachms of acetate, 24 grains of gold (120 grains of chloride of gold to 15 ounces of water), and 6 pints of water, made a couple of days before using, and kept in the dark, and strengthened after using. I am using Eastman's Solio. I find, if used when in a dark state, the prints have a yellowish look. I have used the bath several years for silver paper, and it used to keep well then. Kindly give me a remedy for the same. 2. Will a bottle of water, stood in the sun for a few days, with a few drops of permanganate of potash added, answer the same as distilled water for sensitising?"—1. Unless the toning bath is made with impure materials, which is probably the case, there is something in the paper that has brought about the reduction. In that case the remedy is to make up only sufficient of the solution for the day's use. 2. Yes, nearly; but we should prefer to use a few crystals of nitrate of silver in place of the permanganate.

EX CATHEDRÂ.

The Convention meeting that is being held this week at Leeds, promises, as may be gathered from our reports, to rank high in the scale of success that has invariably attended these gatherings. Apart from its agreeable social aspects, this particular meeting has possessed features of a distinctly useful character which are not likely to have only an ephemeral effect. We may in particular allude to the collection of modern pictorial photographs, arranged by Mr. H. P. Robinson, the President, as establishing a precedent which it is to be hoped will be made use of at succeeding meetings, inasmuch as it indicates in what manner they may be available for educational purposes. Not merely the present position of pictorial photography, but possibly various branches of technique and processes, might usefully be illustrated in this way.

* * *

The President's Address (given elsewhere) is a characteristic production, in which Mr. Robinson airily takes occasion to reiterate his well-known views on the differences between what are called the Old and the New Photography. It is a pity that the Address could not be discussed at the Convention, otherwise much of an interesting character might have been said on several points that it raises. We, however, anticipate that the Address will attract attention in the correspondence column of the photographic press. We heartily endorse the advice Mr. Robinson gives the professional photographer; to endeavour to improve the quality of his work. When the desiderated revolution in professional portraiture arrives, then, surely, there will, or rather should be, a prosperous time for professional photography.

* * *

A question of copyright has been brought under our notice, with the request that we will not publicly divulge the particulars as to *locale* and personality, although we have no reason to doubt the absolute authenticity of the facts. While in a moral sense, no doubt, the "question of copyright" does come in, we are rather inclined to look upon the matter as a "question" of either honour or honesty—at any rate, of good taste.

* * *

It seems that the proprietors of a locally circulating weekly paper have, for some time, been publishing illustrated descriptions of mansions and places of note in the neighbourhood, the pictures being mostly supplied by a professional photographer belonging to the town, though, when the illustrations are taken from photographs by such firms as Valentine & Sons, or G. W. Wilson & Co., due recognition is given. So far so good; but these pictures have appeared bearing the name of the local professional as the author, which our informant—an amateur—avers are from photographs taken by him, or, which amounts to the same thing, from copies of his photographs, for the proprietors of the publication assert that all the *negatives* of the pictures credited to Mr. So-and-So are in their possession. Copies of the reproductions as well as of the original photographs taken by our amateur correspondent which have been sent to us leave little doubt as to who is the original author of the pictures. In other words, there is not the faintest doubt but that the half-tone etchings have been made from the amateur's originals.

* * *

A rather comic side of the question is found in the defence of the professional, who is prepared to "swear" the pictures are his own. He first inquires, sarcastically, whether the amateur "claims copyright in the point of view," and wonders

whether it ever struck him that two people could take a picture from the same standpoint. But it was pointed out to him that there are certain similarities between the amateur pictures and his alleged independently produced ones that are something more than mere coincidences. For instance, in one view, at precisely the same point, and at apparently precisely the same time of day, as shown by the shadows, there appear in both pictures a man and a barrow; and, moreover, a besom, a rake, and a spade are leaning against the barrow in exactly the same positions in each case. In reply to this, the photographer says, that "after inquiry" he finds that the same gardener has been employed on this estate for upwards of twenty years, so that "there is nothing surprising in his appearing in both the photographs." However, it is not the question of the *same man* appearing—for he is practically unrecognisable or uncomparable in the reproduction—so much as his occupying just the same position at the same time of day, and with the very same tools. Gardeners, we know, have to be men of very regular habits; but this, at least, seems to us to be straining a point a little too far.

* * *

However, as a question of copyright—leaving altogether out of sight this particular case—what is the position of a photographer or a publisher who uses his work, who "pirates" the work of another, keeping himself just beyond the bounds of legal proof of his delinquency? For, as in this case, as well as in another of a very similar character that came under our notice some years ago, there may be strong moral evidence that does not amount to proof. In the Gambier Bolton case the only legal proof of piracy was found in the reproduction of the scar or abscess on the tiger's jaw, which, however, served to turn the scale in the interests of justice. In the case we have cited above, if a jury should decide that it was impossible to recognise the gardener as the same in the two pictures, or, identifying him as the same, found that it was not impossible that he might have been taken on two separate occasions, would the other overwhelming "coincidences" have to be put on one side as merely circumstantial evidence of no legal value?

* * *

A correspondent writes, *àpropos* of Mr. Friese-Greene's letter in last week's issue, on the subject of priority of invention in the moving photograph business, that every one seems to have entirely overlooked Muybridge in this connexion, and points out that, some years before the dates mentioned by Mr. Friese-Greene, Muybridge exhibited his apparatus with almost as formidable a name as the more modern ones, both in this country and in Paris, and probably he was the individual referred to by Mr. A. L. Henderson a week or two ago as having exhibited in Brussels. Without referring to published reports, we cannot fix the exact date, but it must have been somewhere in the early or mid "eighties" that we, in company with a distinguished party, including the Prince and Princess of Wales and their daughters, listened to a lecture by Muybridge at the Royal Institution, and saw for the first time his "something"-praxiscope in action, and either the following or the preceding evening we were present at Burlington House when he explained his methods and apparatus at the *soirée* of the Royal Academy.

* * *

There was one very funny incident on the occasion of the lecture in Albemarle-street. The picture on the screen represented a number of deer running in a semi-wild state, in some "park," in the States, and something unfortunately went wrong with the machinery, which began to run more and more slowly, until, finally, it came to a stand-still. Mr. Muybridge was compelled to leave his position on the platform—with a muttered remark that sounded, from our distance, to say the least, suspicious—and proceeded to investigate matters at the lantern. After a short time, things began to move again slowly, but with a most comical result, for a fine young stag, that occupied the centre of the picture, commenced to advance with his fore leg, while his hind quarters remained stationary, until his body appeared to be about the length of an ordinary Pullman car. Then Muybridge looked up, and the light went out suddenly, until matters had been satisfactorily arranged. Although Mr. Muybridge declared afterwards, it was not a rehearsed scene, it was undoubtedly the most popular portion of the evening's performance.

* * *

On the occasion of the same visit to this country, Mr. Muybridge lectured before the Society of Arts, and at Eton College, besides a great many more places, and, although his results were not precisely like those shown at the present time, he can, no doubt, make a strong claim to priority in the matter of public exhibitions of moving photographs.

* * *

It is scarcely credible at the present day, when almost everybody who has exposed a dozen plates wants to write a guide to photography, that there should exist individuals who seem to be really honest in their simplicity, but such a case has just cropped up. An amateur of not immature years was advised a short while back to use starch instead of gum arabic for mounting purposes, but in a few days returned in high dudgeon to complain that the stuff would not stick at all. We suggested he perhaps did not put enough starch on to the print, or, possibly, he rubbed it down too much, and so expelled the greater part of the mountant, but a specimen peeled print had quite the opposite appearance, the starch lying in thick layers on the bare mount.

* * *

Then we noticed that it had a very powdery appearance, and was easily rubbed off, and the cause of the difficulty began to loom in view. "How did you mix the starch?" we asked. "Oh, with water!" "Yes; but did you boil it or use boiling water?" "No, just stirred it up, as you said, into a thick paste." We then proceeded to explain that that way of mixing was not much use, that the starch must be boiled, or, at least, made with boiling water, and must assume the appearance of a transparent jelly. Our friend retired apparently satisfied, but will it be believed he came back next day to tell us that his housekeeper said that starch "didn't want boiling, it was 'cold-water' starch!" We told him he had better take his housekeeper as his photographic instructor, and he would be sure to do well.

POINTS FOR CONSIDERATION IN PURCHASING A PHOTOGRAPHIC BUSINESS.

Our advertisement columns of late have shown that there have been, and are, a large number of photographic businesses in the market. This, no doubt, accounts for the number of letters received with reference to the value of the goodwill of photographic

businesses—whether it is based upon the gross returns or the net profit, &c. We have also received letters as to alleged misrepresentations in the sale of businesses, based upon the circumstance that the purchaser has not done the same amount of trade that the vendor did, or stated he did.

The value of the goodwill of a photographic business—we are dealing with portrait businesses only—cannot be appraised by any set rule, as is the case with many other businesses, so much must necessarily depend upon collateral circumstances. For example, take two businesses, each making the same returns, say, 1000*l.* a year. In the one the prices range fairly high, say, on a guinea a dozen for cabinet portraits base, while, in the other, they rule low—half the price or less. Now, it is obvious that, although both businesses return the same gross receipts, there is a vast difference in the net profits of the two. In the latter, considerably more than double the plates, paper, mounts, and material generally are necessary, as well as considerably more labour, though possibly of not quite so expensive a kind; also it will entail more supervision and business anxiety on the part of its proprietor than will the other, which requires a less number of hands for its working. Hence it will be seen there is a very great difference in the market value of the two concerns.

In estimating the value of many businesses, the average receipts for the previous three years are taken as a basis. When this is done in photography, the last year is the most important for consideration, for it is clear that, if this is less than the previous ones, it shows that the business is on the decline. If, on the other hand, it is more, it indicates that it is increasing, and an increasing business is obviously of more value than a diminishing one. Another matter for consideration is opposition in the neighbourhood. A business that is surrounded by a considerable number of competing ones is clearly not equal in value to one where there are none or very few. A small business is not worth so much proportionately as a moderate one, all things being equal, because, in the former, a certain number of hands must be engaged, such as reception-room attendant, printer, &c., and there is often not sufficient work to fully occupy their time, whereas there is in the latter. Therefore the labour costs no more in the moderate business than it does in the smaller one, where a larger amount of work is turned out.

Considerable importance is often attached to the number of negatives in store. At one time this was a more important item than we are given to understand it is now, except in the case of publication portraits, because, as prices are now generally much lower than they used to be, so many, especially ladies, prefer to have fresh sittings in their latest costumes to ordering duplicates from old negatives. Therefore, except in the case of deceased persons or notabilities, a large collection of old negatives is not worth what it used to be in former times.

Here is another point that should be considered in purchasing a portrait business, namely, the lines upon which it has been run for the previous year or two. For instance, a man may start a business in a small provincial town, and by dint of great enterprise work up a good trade in a year or two which is *bonâ fide* as the books show it; but during the time the residents have become so well stocked with photographs that comparatively few more will be required by them for some time to come. The trade in the place has been exhausted for a period. To use a common phrase, "the orange has been sucked pretty dry" before it is parted with. Purchasers of such businesses have often lamented their bargains, though there was no misrepresentation whatever as to the amount of trade that had really been done.

In a photographic business individuality is a very important factor. In a sense a portrait photographer is somewhat analogous to a medical man. The latter may dispose of his practice, but it does not follow that the patients will be transferred with it, although the new man may be as able a practitioner as his predecessor. The same frequently happens in photography. The new comer may not be so well liked in the studio by the sitters as was the previous proprietor, or maybe a neighbouring artist may be liked better, yet his work may be, photographically, as good, or even better. Of course, that is a matter the vendor of the business cannot control. We have known in cases of this kind of allegations being made that there had been fraud and misrepresentation as to the returns, though, of course, they were groundless. We should not for a moment say that there has never been misrepresentation in the sale of a photographic business, because we know there often has been, as there has been in the case of most other businesses.

Here is another point to have in view when buying a photographic business. It is customary to bind the seller over not to carry on a similar business within a certain radius. That, of course, does not apply to any of the *employés*. If the studio has been much left in the hands of an operator, who is well liked by the sitters, and he leaves and starts in business for himself, or enters the service of another photographer in the neighbourhood, the business of the old concern is likely to suffer badly, particularly if the incomer is not of agreeable manners, or if he does not produce the same kind of work as was formerly turned out. There is always the possibility of this kind of thing happening when a business has been mainly conducted by *employés*. We have here made no estimate as to the value of photographic businesses, large or small, but merely call attention to a few points that purchasers would do well to give attention to, as by so doing they will often avoid after-disappointment.

Electric Light Peculiarities.—An instructive instance of the effect of the atmosphere acting on a turbid medium on light has recently been discussed. Photographers are unfortunately too familiar with the actinic-light filtering powers of fog upon sunlight, and the same effect upon the visual constituents of electric light seems to be produced by mists. It appears that since the loss of the *Drummond Castle* the attention of Government has been called to the fact that, since the use of the electric light in lighthouses, vessels have been lost in close proximity to these beacons, though possessed of some of the most powerful electric lights in the world. Close to Dungeness, Lizard Point, St. Catherine's Point, and now off Ushant, vessels have been wrecked, and the survivors have stated that the lights were invisible though but a slight distance away.

Astronomers' Troubles.—The discomfiture of the unfortunate photographer who discovers, on setting up his camera a long way from home, that it has been kept in a damp place and will not "fit," is well known and sufficiently real. It is in a similar direction paralleled by the mishaps recently chronicled by the Astronomer Royal for Scotland. Every one knows the important part played in astronomical work, whether visual or photographic, by the "driving clock," and this is where the trouble has happened. Sir Howard Grubb's two clocks work perfectly, but the one for the 15-inch equatorial, which, for stability and freedom from changes of temperature, has been built in a chamber in the middle of a mass of brickwork, further protected by slag-wool-lined doors, is in danger. This

central chamber turns out to be quite damp owing to the evaporation from the cement or mortar used in joining the bricks, &c. Meanwhile everything is being done to remedy matters, unslaked lime and anhydrous chloride of calcium being placed so as to absorb the moisture. It is anticipated that, when the mortar is quite dry, all will be well. Any one who knows anything about bricks and mortar would be sorry to state how many years would have to elapse before that consummation would be arrived at.

Prognosticating the Weather.—A correspondent writes in reference to our paragraph on this subject in last week's issue, asking if the theory of the spectroscopic forecasting of the weather has been altogether abandoned. He says, and we know it to be a fact, that the theory of the so-called "rain band" met with a considerable amount of opposition; but we believe, speaking from recollection as well as from our own personal experience, that the truth was, that whereas in a fairly clear atmosphere—as in the country—the rain band formed a tolerably, if not an absolutely, reliable forecast of rain, in the smoky atmosphere of town it is either altogether invisible, or may be caused by other influences than aqueous vapour. Our own experience with a little pocket spectroscope agrees with that of our correspondent, in that we have invariably found the appearance of the rain band—in the country, at least—to be followed by rain within a few hours. Indeed, on one occasion we brought down a vast amount of ridicule upon the rain band, as well as Professor Piazzi Smyth, when we discovered it in a blue and almost cloudless sky, and when the barometer gave not the least indication of any change from "set fair." But there was a violent downpour, accompanied by a thunderstorm, within an hour and a half.

Increasing the Rapidity of Röntgen Work.—We have already detailed some important discoveries bearing on this, and in last week's *Nature* another variation is described by Mr. T. G. Crump of Burnley. It consists in "placing the flame of a small spirit lamp in the angle formed by the Crookes' tube, the wire passing to the cathode and allowing a series of small sparks to pass to the flame from the wire."

But, at the Royal Society's meeting on June 11, Mr. A. A. C. Swinton brought forward a series of remarkable experiments he had been making upon the action of a magnet upon the cathode rays. He was enabled to focus the rays very sharply upon a point inside the tubes, but when so treated the external issuing rays were profoundly modified in character. The form of tube used was the earlier form of "focus tube," shaped like a pear. According to a note in *Nature*, with Mr. Swinton's signature, since these experiments were made, a further series have been carried out. He writes (*Nature*, vol. liv. p. 239):—

"With a tube of the form shown, exhausted to an extent that gave X rays plentifully under ordinary conditions, and supported over an electro-magnet, the X rays disappeared as soon as the magnet was excited, but reappeared the moment the magnet was demagnetised.

"With another tube of similar form, but furnished with an inclined platinum plate forming the anode placed near the bottom of the tube, similar results were obtained. This tube being kept on, the pump was further exhausted to a degree that allowed the electric discharge to pass with difficulty when the magnet was not excited, and under these conditions gave X rays of a character that penetrated the bones of the hand almost as easily as the flesh with but little contrast. With this exhaustion the excitation of the magnet not only caused the cathode rays to focus on the platinum, thus giving sharper shadows, but at the same time had precisely the same effect as lowering the vacuum, in so far as the moment the magnet was excited the X rays became more plentiful, and became of such a character as to penetrate the flesh with much greater ease than the bone, so that the contrast between bone and flesh was exceedingly marked. A photograph of the hand taken with one minute's exposure with the tube in this condition, and with the magnet excited, though considerably over-exposed, proved to be a very good one. Further investigations are in progress, but the application of a strong magnetic field in the manner described gives promise of having considerable practical utility, not only in so far as it facilitates the accurate focussing of the rays proceeding from a flat cathode upon any desired point of the platinum anode, but also, and more especially, because by employing a high exhaustion, and by varying the intensity of the magnetic field, it is possible at will to arrive with ease at the exact conditions requisite to produce a maximum of X rays of exactly the penetrative character that may be best for any given purpose, a result which hitherto has been difficult of attainment."

Iodine after Fixing.—We have repeatedly, in these columns, written down the practice of using hypo eliminators, that is to say, of using chemical means to decompose the hyposulphites remaining in negative or positive films after fixing. One of the substances formerly recommended for this purpose is iodine, which, however, we have on a former occasion shown, is calculated to leave quite as dangerous compounds behind it as the hyposulphites themselves. A very forcible proof of the truth of this has just been presented to us in an indirect manner. A correspondent writes that, in intensifying collodion emulsion negatives after fixing, he invariably gives a preliminary wash of weak iodine solution, which materially aids the process of intensification; but latterly he has been troubled at intervals with the appearance, at some stage of the operation, of a faint, though sometimes very marked, opalescence in the transparent parts of the plate, which looks as if it had not been thoroughly fixed. But neither hypo nor cyanide, nor, in fact, any treatment he has tried, will remove it, and before intensification has been completed the opalescence has been converted into a deep ruby stain.

After careful investigation, he has traced this evil to its source, which is, originally, imperfect fixation, possibly aggravated by insufficient washing. The films, consisting of bromide of silver, are fixed with hypo, and if the operation be not thoroughly performed, or if the washing be hurriedly done, there will remain a certain portion of soluble, and semi or insoluble, silver salts. If iodine be now applied, there will be a visible formation of iodide of silver; the iodide, being less soluble in hypo than the bromide, is precipitated, and, if the plate be now refixed in either hypo or, preferably, cyanide, not much damage will be done, provided a careful washing be given.

But, if the danger be not suspected, and intensification be proceeded with, the opalescence we have mentioned first appears, and this eventually increases into a deep and indelible stain. We cannot follow out the precise chemical changes that go on, but may repeat what we previously said, namely, that one of the results of the reaction of iodine and sodium hyposulphite, or thiosulphate, is the formation of sodium tetrathionate, and probably other of the thionates, and, if silver hyposulphite be present, there will, of course, be the corresponding silver salt. This, as the experience quoted shows, is, as we have before stated, at least as dangerous as the salt decomposed, and, controverts the opinion so frequently expressed that no eliminator is so safe as honest washing.

PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

Leeds Meeting, Monday.

The Eleventh Meeting of the Photographic Convention of the United Kingdom commenced on Monday last at Leeds in beautiful weather, which, if it should prove to have continued throughout the week, will go far towards making the Convention a memorable one. We have little doubt that, when the history of this Convention comes to be at leisure reviewed, the word "success" will be applied to it with as much readiness as it was to any of its predecessors.

Leeds is grimy, prosaic, and intensely matter of fact, but it is earnest, a valuable quality of which the members of the local photographic Society, who have taken in hand the work of organization, possess their full share. During the past few weeks much heavy

work has had to be gone through to ensure the programme being worked off smoothly, and the arrangements come to were well calculated to achieve that end. The Local Executive Committee consists of Messrs. John Henry Walker, Chairman; B. A. Burrell, F.I.C.; Peter Gilston, J.P. (Ex-Mayor), President Leeds Photographic Society: Washington Teasdale, F.R.A.S., &c.; Dr. Thomas Thresh, Ph.D., L.R.C.P.; W. J. Warren; H. F. Wigglesworth; Herbert Denison, F.R.P.S., Hon. Treasurer: and Godfrey Bingley, Hon. Secretary, Thorniehurst, Headingley, Leeds; and one and all of these gentlemen have applied themselves to the work of organization and arrangement in the most thoroughgoing manner.

Saturday and Sunday brought a number of arrivals from distant parts of the kingdom to the Convention headquarters, the Queen's Hotel. Mixed with the old faces that have been seen at all or most of the preceding Conventions were many new ones. Early on Monday a stream of arrivals appeared, and the Philosophical Hall, at which the meetings are to be held throughout the week, was crowded with members taking tickets for the week's excursions, exchanging greetings.

The meetings of the week, with the exception of the Reception, are being held in the rooms of the Philosophical Museum, which, in addition to a lecture theatre placed at the disposal of the members, allows of the use of three galleries for Exhibition purposes, as well as offices where Mr. Drage, Mr. Walker, Mr. Bingley, Mr. Dennison, and other members of the Local Committee conducted the business transactions of the Convention—no light task, especially as regards the clerical work attendant on the issue of tickets.

The Exhibition of Pictorial Photographs.

This Exhibition, which has been organized by the President, Mr. Robinson, is hung in the Library of the Museum—a well-lit apartment which is excellently adapted for the purpose. There are about 115 photographs, selected chiefly from those that have been hung at the Exhibitions of the Salon, with the addition of a few works that antedate that Institution, and one or two that are quite new. The hanging has been most ably done. The bookcases are covered with a dark purplish-brown cloth, which forms a good background. We were pleased to observe that very early in the day the Library received a good number of visitors, who manifested great interest in the photographs.

It would be easy for us to pick a just quarrel with Mr. Robinson for having given the display a too Salonic character; but, inasmuch as it is Convention week, and the display is really a good and beautiful one, we refrain. One thing, moreover, for which we think Mr. Robinson is entitled to the thanks of Leeds Conventioners and photographers generally is in having set his face against including in his display any of those preposterous eccentricities which have formed the amusing element in the Salon Exhibitions.

Among the exhibitors are Messrs. Arthur Burchett, J. Craig Annan, Shapoor N. Bhedwar, W. Crooke, Demachy, F. Hollyer, E. R. Ashton, Ralph W. Robinson, H. P. Robinson, F. M. Sutcliffe, H. E. Davis, Karl Greger, G. Davison, A. Horsley Hinton, B. Alfieri. Most of these gentlemen are represented by the works with which they have recently been prominently identified, and that have been referred to in these pages, and therefore a detailed reference to them is unnecessary, although, to give our readers at a distance an idea of the general appearance of the Exhibition, we may say that it includes several of Burchett's figure studies, Annan's portraits, Bhedwar's "naver" series, Crooke's portraits, Hollyer's portraits (one of a young lady with her head against a door knob is conspicuously not at Mr. Hollyer's best), Ashton's Eastern scenes, Mr. H. P. Robinson's land and seascapes (including *Storm Clearing Off*), Sutcliffe's *Water Rats*, Davison's *Onion Field*, Horsley Hinton's *Day's Awakening* and *Day's Decline*, &c.

The *Leeds Mercury* says of the Exhibition: "Any one interested in art should, under no circumstances, miss the opportunity thus afforded them of examining a very beautiful collection of work, produced by several of the most skilful photographers of the day. There is an agreeable surprise in store for those who are only acquainted with the style of picture ordinarily turned out by the knights of the Camera. The majority of the prints shown in the Exhibition are, in every sense of the word, works of art."

Our contemporary terms Mr. Davison the "Whistler of photography." Of Mr. Lionel Bennett's Thames study, *Inward Bound*, it remarks: "We should have imagined it too easy a matter to produce a foggy photograph to make it worth an artist's while to photograph a fog."

Exhibition of Apparatus and Photographs.

Besides apparatus, this section of the Exhibition includes a number of photographs by various processes. The display is spread over the entrance hall and two of the galleries, which are filled with geological and other specimens.

Taylor's Drug Company, Leeds.—This firm has a large case of hand and stand cameras, &c., placed in the entrance hall.

Watkinson & Co., Leeds.—The members of the Convention were invited by Messrs. Watkinson to visit their apparatus works, and many, no doubt, availed themselves of the privilege. The firm's display in the museum included two large cases, showing cameras in parts, finished cameras, light stands, and a variety of other items of apparatus, apparently of good quality and undeniably cheap.

Reynolds & Branson, Leeds.—The high reputation held by Messrs. Reynolds & Branson justified us in looking for an excellent exhibit from them, and we were not disappointed. A case of Ross and other lenses; a variety of extremely well-made cameras, including a fine photo-micrographic instrument; a well-filled chemical cabinet and specimens of apparatus for X ray work formed some of the firm's exhibits, the remainder of which were both good and interesting.

Percy Lund & Co., Bradford.—Specimens of printing in half-tone and colours were included in Messrs. Lund's exhibit.

The Aërograph Company, Memorial Hall, London, E.C.—Some very beautiful examples of the use to which the air brush may be put in the working up and finishing of enlargements are shown by the Aërograph Company. Examples in colour are also included. The quality of the results yielded by this method of distributing liquid colours convinces us that photography will continue to regard the Aërograph with great favour. The results are very popular with the public—especially that large section of the said public which is not yet educated up to "pictorial" photography.

R. & J. Beck, Cornhill, E.C.—The stand of this well-known house is devoted to specimens of the new 5×4 Frena, an ingenious little collapsible pocket and opera glass, a simple clip for attaching as a luggage carrier to cycles, the Bynoe printing frame, and other specialities. Mr. Bynoe was in charge at the time of our visit.

Pearson & Denham, Leeds.—Examples of cameras, stands, packages of dry plates, &c., adorned this firm's stall.

Wellington & Ward, Elstree.—The Elstree house contented themselves with sending two frames of prints in their Sylvio and platino-bromide papers. As examples of faultless technique these prints would be difficult to surpass.

Elliott & Son, Barnet.—A large bromide enlargement, measuring at a guess nine feet by four feet, and handsomely framed, is Messrs. Elliott's sole contribution to the Exhibition. It hangs in the lecture room. The negative, by Mr. James Bacon, is that of a lady, full length, and the enlargement forms a striking and effective adornment of the room, the quality of the work being exceedingly good throughout. The tone of the enlargement is a peculiarly rich black.

The Eastman Company, 115, Oxford-street, W.—The four well-known printing processes of this firm—nikko, bromide, solio, and platino-bromide—are illustrated in their exhibit, which includes about a dozen frames of subjects. The nikko pictures are particularly fine and rich, and make the popularity of this process not difficult to realise. Some well-chosen portraits, figure studies, views, and snap-shots are used for illustrating the capabilities of the Eastman printing processes, and the display is a thoroughly good and artistic one throughout.

We here take the opportunity of mentioning that the members of the Convention are indebted to the Leeds Photographic Society for handy maps of Leeds, York, and Bolton, which were presented to every one attending. These maps are found useful guides.

The Reception.

The formal opening of the Convention took place in the evening

at the City Art Gallery. This is an imposing building, containing galleries filled with a fine collection of ancient and modern paintings, and for such a function no better venue could have been selected. It will be remembered that last autumn the Leeds Corporation promoted a photographic and black-and-white exhibition, which was held in this building.

In the unavoidable absence of the Mayor (the Right Hon. W. L. Jackson, M.P.), the Deputy-Mayor (Mr. John Gordon) received the members of the Convention, to meet whom a very large number of local ladies and gentlemen were invited. The scene when the galleries were filled was a beautiful and animated one, and it was felt on all sides that the Convention had been highly honoured by the magnificence and appropriateness of the surroundings in which it had been received.

During the evening the band of the Eighth (King's Royal Irish) Hussars played a selection of music, and light refreshments were provided. The company numbered several hundreds. Among the photographic notabilities present we observed Mr. H. P. Robinson and Mrs. Robinson; Mr. A. Haddon, retiring President; Mr. C. H. Bothamley; Mr. George Mason; Mr. Andrew Pringle; Mr. John H. Walker, Chairman of the Local Committee; Mr. H. Dennison; Mr. Godfrey Bingley; Mr. and Mrs. F. P. Cembrano: Mr. Harold Baker; Mr. R. P. Drage; Mr. C. S. Baynton; Mr. H. Sturmey; Mr. F. A. Bridge; Mr. H. M. Dennis; Mr. J. Howson; Mr. W. Crooke; Mr. S. B. Webber; Mr. C. Phipps Lucas; Mr. F. W. Williams; Mr. M. J. Harding; Mr. J. Porritt; Mr. W. Barry; Mr. T. Fall; Mr. E. J. Wall; Mr. A. Horsley Hinton; Mr. and Mrs. Snowden Ward; Mr. Hubert J. Elliott; Mr. F. O. Bynoe; Mr. J. L. Lyell; Major Lysaght; Mr. A. C. Baldwin; Mr. J. Stuart, Glasgow; Mr. A. L. Henderson; Mr. and Mrs. Percy Lund; Mr. A. F. Mowll; Mr. F. W. Hindley; Mr. J. J. Briginshaw; Mr. D. J. O'Neill; Mr. A. Tate; Mrs. Stevenson; Mr. C. B. Keene; Mrs. Keene; Mr. C. Winter; Mr. E. R. Ashton; Mr. E. and Mrs. Woodward; Mr. W. W. Naunton; Mr. T. Scotton; Mr. W. J. Warren; Mr. Washington Teesdale; Mr. Thomas Bedding; and very many others.

After the guests had made the tour of the various galleries, they gathered in the large Central Court, the Mayor being supported by the past Presidents of the Convention,

Mr. John H. Walker introduced the past Presidents of the Convention and the President to the Deputy Mayor, and said that it gave him peculiar pleasure to do so inasmuch as at Shrewsbury he was the mouthpiece of the Leeds Society in inviting the Convention to meet in their town. He alluded to the Convention as consisting of good fellows, and, remarking upon the fact that photography entered largely into every-day life, invited the Deputy Mayor to welcome the Convention to Leeds.

The Deputy Mayor, having apologised for the absence of the Mayor (Mr. Jackson), who was detained in London by his Parliamentary duties, remarked that many years ago photography was not recognised as an art. That time had passed, and it now took its place among the arts. He was grateful for what retouching did in portraiture, and he only wished it could smooth the wrinkles out of our lives as well as out of our faces. He was delighted that Leeds had been recognised as a fitting place for the meeting of the Convention, and he bade the members a hearty welcome, and assured them of the sympathetic interest of the inhabitants of Leeds.

Mr. Haddon, having introduced Mr. Robinson to the meeting, the Presidential address was read by Mr. Bothamley.

PRESIDENT'S ADDRESS.

When, five years ago, I was nominated for this honourable position, I felt compelled to decline, knowing that I could not carry out the duties as they should be carried out, having a defect of voice which would not allow me to read my own address. The Convention was greatly the gainer. By retiring, I made room for one who is a born organizer of photographic matters, a powerful and ready speaker and writer, and a true artist. I have recently re-read Mr. Davison's address to you at Edinburgh, and was delighted with its power, eloquence, literary skill, and almost prophetic sense. Although only a few years ago, we were then not far from the revival of pictorial photography, and, putting on the "vinegar and brown paper" after the battle of the styles, we now feel we are nearing success, and perhaps peace, although there are still clouds on the horizon. I have used the term, "revival of pictorial photography," because I think we sometimes want reminding that photography did not begin with the bromo-gelatine process, as some suppose poetry originated with Rossetti and Swinburne, forgetting Homer and Shakespeare, and some other ancient rhymsters. But I am digressing early.

At our Shrewsbury meeting I was waylaid at every corner by amiable councilmen and even prospective presidents, who suppressed their own claims, and asked me to preside over you, therefore what could I do but succumb, demanding however, and obtaining, a dispensation for all shortcomings. And now I feel at once proud and humble—proud of being drawn for a brief period to take the head of this noble body of photographers, and very humble, indeed, when I consider my inability to occupy a situation which almost any one of you is capable of adorning.

What is Photography?

In a presidential address, delivered before a Society which meets but once only in the year, it may be expected that a full summary should be given of the progress of the subject which brings that association together. I have carefully thought this matter over, and have come to the conclusion that nothing of the kind is possible in our case, the principal difficulty being that nobody can say with any confidence what photography is. At a Camera Club conference, in the course of discussion, a member once asked, in the most artless and innocent manner, "What is photography, Mr. President?" There was a blank pause, as if something dreadful had happened. Some of the audience looked wise, others doubtful, but few could have replied offhand. The result is, that we have now the dictum of Captain Abney, the greatest photo-scientific authority, that photography is "painting by light." If we acted on this judgment, it would enable us to clear off a crowd of encumbrances that have been crushing legitimate photography of late years, and obstructing our true subject. It seems clear to me, for instance, that, looking at our art as a business, the many subsidiary inventions we so eagerly welcome are taking photography out of the hands of photographers, and placing it in the hands of other trades. Take what is now the chief of these parasites, that which is called "process," what has that to do with photography? It is a printing and engraving business that gets all it can out of photography. It is the cuckoo in the hedge-sparrow's nest that is quickly elbowing the genuine bird out of its own cradle. The promoters of "process" have much to answer for to the photographer.

Then, again, how am I to enumerate all the progress that science—the genuine science of photography—has made during the year? How winnow out the false, and leave the true? And what is the use of saying anything this year about what may be altered by the next, for the science of photography is a paradox? Science is said to be the art of facts, or certain knowledge. Everything is proved as we proceed, but in the science of photography we soon find, with Macbeth, that "nothing is but what is not." There seems to be nothing more unstable than fact, and a photographic society appears to be but a branch of the College of Laputa.

But, if much that is called photography has no right to the name, there is not anything—neither the oldest nor the youngest of the arts and sciences—that is not indebted to our art. The most sublime of the sciences—astronomy—owes to the art which takes the portrait of the humblest child in the automatic machine in the streets, its greatest triumphs.

The "New Photography."

It is curious how everything claims affinity with photography. There must be something worth claiming in the word. A method of showing your naked living bones by aid of the dark rays of a Crookes' tube has not only been called photography (or light painting, where there is no light), but those who have been spending their time with it have gone to the preposterous length of calling it "the New Photography." Now, this is not only ignorance, but rank piracy. The term, "the New Photography," has been used so much in connexion with the forward movement in pictorial photography that the pictorial photographers ought to have acquired a copyright in the title. Any fine morning in October, the traveller in Piccadilly may observe twelve or twenty sandwichmen bearing aloft the banner of "the New Photography," in connexion with the Photographic Salon. It is a wonderful discovery; but is it photography, especially the New Photography?

Last year I think I gave a sort of informal promise that I would not touch on art in this address, but would confine my remarks to abstract, if not occult, science. This, I think, was made at

gathering of sometimes misunderstood science, welcomed throughout the world as the A.M.S.; but, on reconsideration, I cannot help supposing that it will be expected that I say a few words on the branch of photography to which I pay most attention.

Advances in Pictorial Photography.

I think it must be admitted that pictorial photography has made great advances the last three or four years. The initiation of the Salon was the outward expression of what has become nothing less than a revolution in pictorial photography. The Salon was not an accident. It was thought over and discussed for some years before it was attempted. It was received with derision, and the usual endearments which try the quality of every new thing that is worth trying; it not only withstood the onslaught, but it converted all opponents worth converting, and made them into very good friends; and the Salon is now an institution that, I believe, no true photographer would willingly let die. And what is the theory of the Salon? The main intention of its promoters was to keep pictorial photography (which was in some danger of extinction) pure, and to itself, and to lead it out of the groove in which it was withering. It was a struggle for liberty, for freedom from conventionality, for individuality. The object was to look to the end, to make a good picture without being dragged away by side issues; to treat the materials as our tools, and not the main or sole consideration; to be content with a negative when it was adequate, without measuring its density, or trying to prove that, if another similar plate were exposed under the same conditions, the photographer had no power of making other than a facsimile of the first; feeling and expression in the print were to be more valued than the bloom on the film; that how a picture was made was a matter between itself and its maker, which could not be described in a formula; and, in short, that there should be a great deal more of the mind of the man than evidence of his camera. Under these auspices, landscape has become from being an unemotional transcript of a view a sympathetic interpretation of dominant characteristics, and portraiture raised to a dignity to which it has not hitherto aspired.

There is this difference between many of the pictures in the exhibitions under the old *régime* and the new. In the old, the photographer seems to have selected the view, and the camera did the rest, whether the photographer liked it or not; in the new, if there is any evidence that a camera was used, it was only as a tool under control. If one or two exhibitors, in their zeal for originality, have overstepped the borders of the sublime, with the usual unfortunate consequences, who shall blame them? I hold that not one of their apparent failures has been wasted; there has been more use in some of the much laughed-at lunacies than in acres of what, for want of a better phrase, we may call "the usual thing." It was soon found that those who came to laugh remained to praise. The eccentricity of yesterday, if it has not become the commonplace of to-day, has evolved from a thing to be laughed at to be something to think over.

The work of the extremist is done, and it is now left to the more moderate to show, as it has never been shown before, that even a photograph, as Zola says of other works of art, is "a piece of nature seen through the medium of a temperament."

Wanted—A Revolution in Professional Portraiture.

The subject of pictorial photography is one on which I easily become enthusiastic; but I have introduced it here with a definite practical purpose, as well as because I thought you would expect it.

Some of you are professional photographers, and I am told that the business is not now so good—with those particularly who never attend this Convention—as it used to be in former times. Now, my firm opinion is that there wants some such revolution in the portrait profession as has taken place in the opinions and practice of those whose chief aim is pictorial photography. The way to that desirable goal is through harder study of art, on entirely different lines from what is usual, and the greater confidence which knowledge brings.

We make no attempt at originality or individuality. Let the thought I am about to state take hold of you and awaken your consciences. This very day, bad as the times are, the professional photographers of England have taken many thousands of portraits. These "counterfeit presentments," with very rare exceptions, are all manufactured to the same conventional pattern, with very little variation, since—let us say—the cabinet portrait was introduced. Do you wonder at the public getting tired, even of beautiful mauve albumenised paper and billiard ball retouching, the stolidity of the stiff pose, or the strain in the pictures of those who attempt "a grace beyond the reach of art?" Are you surprised that the public rush for the quiet simplicity of those portraits which appear almost too simple to be art, but which are all art, that have been shown you in the Salon? With regard to the public, I met with a curious illustrative example only the other day. A month ago I was one of between two and three hundred guests at a double wedding. The previous day I had an opportunity of suggesting that a professional photographer should be engaged, and was crushed by the reply, "We are tired of highly polished professional photography," and thus what I know would have been a very large order was lost.

I am, perhaps, becoming too dictatorial, and really feel I must apologise; but to me the decline or stagnation of photography is like the illness of a personal friend—I cannot stand by and see it die without an effort, however ineffectual.

Now, as I have indicated, what we want in professional photography is some such revolution as we have had in the pictorial division. I am much among photographers, and find that, when a man gets out of the old groove, it shows that the thought he is using is his own, and not his neighbour's; if he has any skill on the pictorial side, he succeeds. I also notice that no man will care how low his neighbours drive their low-class trade, so that for whatever he charges he gives money's worth in quality. It may interest some photographers to know that there are often sold at the Salon, and the purchasers value them as treasures, simple untouched prints, at from two to five guineas each—not according to size or weight—which the ordinary photographer would value at less than half-a-crown a square foot. They are not even on mauve albumenised paper, and possibly not retouched, yet it is thought that quality accounts for the price.

A Plea for Specialism.

In connexion with portraiture, there should be plenty of room in large towns for specialism. I only recollect two specialists, but they did well—Adam Salomon and Camille Silvy. The latter was the first in time; the only kind of photograph he produced was the *carte-de-visite*. He also confined himself to one quantity and one price (forty copies for two guineas), and, when he had taken forty sitters in the day, nothing could induce him to take another. His carriage was in waiting every afternoon to carry him away from the importunity of his would-be clients. Surely this was good business, not beneath the attention of the modern photographer. Adam Salomon was the other specialist I have known, he produced one kind of picture only; it measured 10½in. by 8½in., and was covered with a piece of glass, but not framed. His price for the first copy was one hundred francs, or 4*l.*, and it was worth it. Another praiseworthy characteristic of Salomon was that he selected his sitters. If he judged a sitter unworthy of his camera, he declined to photograph him.

Photography has given a Loftier Tone to Art.

Much as his work wants improving, the portrait photographer has done a worthy work in the world. I could appeal to your feelings as to the aid his work has been to family affection and the domestic relations, but this has become rather trite. I can, however, point out a fact that I don't think has had the attention it deserves.

There are not many painters, perhaps, who are prepared to acknowledge the fact that photography has not only improved their drawing, and light and shade, but also their taste, and the taste of the world. We no longer see any very great absurdity in a painting—None of the old background horrors, for instance. But I mean deliberately to go a great deal further, and I believe I am perfectly sane when I say that photography has given a loftier tone to art altogether. I feel that this statement requires to be illustrated, if not mathematically proved. Years ago, before the beneficent influence of photography, everybody who could draw a line claimed to be an artist, and his claim was allowed. If he claimed to be a professional, he looked down with contempt on the most accomplished amateur. Photography is more particular, and has taught us to look for other qualities besides the mere use of the pencil, the brush, the chisel, or the camera. A man is no longer an artist because he can make a picture, any more than the writer of doggerel is a poet.

I am afraid I have used up my time, and shall weary you, but there is one other subject to which I must allude, and I hope I shall not be misunderstood.

A Word for Pure Photography.

The Council of the Convention has decided to spend its surplus money in the endowment or encouragement of research. I am not sure that I ever heard of any good ever having occurred from small money grants for scientific research, but it is possible, and I shall look for the practical results in this case with great interest. In the mean time, I should like to see research made for all the dead and gone and useless inventions that have clogged and hampered photography, that they may be utterly destroyed out of the memory

of the most rabid experimentalists—those who have been smothered for years—and allow them to breathe once more the fine air of pure photography. After more than fifty years, we want a spring cleaning.

I should also like to see a commission appointed to inquire into that great question to which I have already referred—"What is photography?"—that we may know where we are. At present, many of us seem to be following other arts and sciences, using photography as an excuse, the professionals going into other trades, but not bettering themselves; the amateurs, on the excuse of the lantern, going into voyages and travels, and other alien subjects. In fact, we have given ourselves away. We have made ourselves too cheap. The prosperous times of photography were when we were more nearly pure photographers.

This was thirty years ago, when hundreds of us lived where, metaphorically speaking I hope, thousands now starve. We are all apt to rejoice whenever some invention makes another opening for our wonderful art, or our art makes possible another business. But where does this generally land us? To take one case. Who makes our local views? German printers; or, if they are made in England, it is in a manufactory by a firm. I remember when nearly every professional photographer derived some income from the sale of views of his town. There was another difference. In those days a photographic view sold freely for a few shillings, and was valued by its purchaser; now a copper is the splendid remuneration for a splendid German print! They are no longer the personal productions of the photographer, but are hawked from town to town by the carpet-bagger, and we get process prints of all round the world for sixpence, if we can only get a coupon permitting the purchase from the local newspaper office.

No Difference Between Amateurs and Professionals.

But what am I doing?

I am recognising that there is such a thing as professional photography. On an occasion like this, and, indeed, on all other occasions, I would prefer not to note any difference between professionals and amateurs. I have belonged to both, and find the amateur by far the most exacting position. My experience is that when you are a professional, you attend to your own business, and when an amateur you look after that of everybody else. Let us all be known as photographers—those, I mean, who practise photography—and brothers in the art we all love.

But, whether professional or amateur, let me, in concluding this inadequate address, wish you, in work or play, increased success, and, in the watchword of this Convention, to "cheer up."

At the conclusion of the address, the usual votes of thanks were passed and acknowledged.

The Reception passed off with great *éclat*, and will long be remembered by those who were present for its brilliant success. The evening concluded with an exhibition of lantern slides, illustrating the Shrewsbury Convention and Bolton Abbey.

Tuesday.

Compared with the corresponding period of previous years, the Leeds Convention is numerically ahead of all its predecessors, more members having joined, so far, than on former occasions. Doubtless, when the total comes to be made up at the close of the week, it will be found that this superiority has been maintained throughout.

The National Association of Professional Photographers was instrumental in drawing many of its members to the Convention; and it is to be hoped that the professional element will continue to expand at these gatherings. The opportunity for the interchange of ideas and comparison of experiences should prove an incentive to photographers to support the Convention, and be present at its meetings.

The weather throughout the day was bright and pleasant, and about 120 members undertook the excursion to Bolton Woods and Abbey. The charming well-wooded grounds, the river, and the ruins of the old Augustinian Abbey supplied plenty of opportunities for photography, about 1000 exposures being made. An excellent luncheon at the Devonshire Arms Hotel wound up an enjoyable day, and the party returned to Leeds well pleased with the outing.

The programme for the evening included the reading of a paper by Mr. A. Haddon on the *Fixing and Washing of Paper Prints*—this will appear in our next—followed by a display of lantern slides illustrative of Kirkstall and York. In the discussion that followed,

Mr. B. A. Burrell said that he had heard Mr. Haddon's paper with great pleasure. Anything that he said on the subject was worthy to be taken with respect.

Mr. S. B. Webber inquired which was the most efficient way of applying the water in the washing of the prints.

Mr. C. H. Bothamley remarked that it was an extremely useful thing to have presented to the Convention a summary of the four pages that Messrs. Haddon and Grundy had read on the subject of the fixing and washing of prints. Some complete nonsense was to be found in photographic literature as to the time solutions got in and out of a film. Some solutions diffused in and out at very great rapidity, as an example of which he cited the fixation of gelatine negatives. In reference to the information Mr. Haddon gave as to the amount of silver left in a print after it was fixed and before it was washed, Mr. Bothamley observed that this depended upon the total volume of fixing solution, and the strength of the solution. Taking ten ounces of hypo solution to fix a certain number of prints, and twenty ounces for a similar number, there would be half as much silver left in one print as in the other, but just the same amount of hypo. This was an example of the complexity of the question. He believed in short over long washing. It was a fatal thing, too, to allow prints to stick together in washing, as this prevented the elimination of a solution from the film. He took exception to the theory that the chief cause of the fading of prints is the hypo left in them.

Mr. Andrew Pringle remarked upon the necessity of our prints being permanent, condemned hypo eliminators and long washing Nothing had been done to approach the work of Messrs. Haddon & Grundy in removing such mischievous ideas. As to how the fixation of a print ought to be done, his own opinion was that, if the solution of hypo is sufficiently strong, and of the proper temperature, and not acid, fixing would take place in a very reasonable time. He was shy of fixers containing free acid. The presence of acidified sulphite gave clear negatives, and obviated the use of alum, but this was the only gain. As to washing the hypo out, he pointed out that hypo was extremely solvent, and only wanted the access of water to complete solubility. He recommended the use of a rose tap for non-professional use, and believed that washing in water often changed would thoroughly remove hypo from the print.

A member believed that the introduction of acetate of soda in the toning bath had paved the way to the fading of albumen prints. He used to wash every print with a sponge on a glass plate, and gave half an hour's washing. He had thirty-year-old prints, toned with alkaline gold, that showed no signs of fading.

Mr. J. Stuart (Glasgow) agreed with Mr. Haddon as to the sufficiency of short washing. He had always been puzzled as to the compound left by insufficient washing, and believed it was a silver compound. Years ago, when using the borax bath, his prints were covered with little white spots; other photographs had the same complaint, and in every case the borax bath was used. His own belief was that the nitrate of silver left in the paper should be converted into chloride, and he therefore always treated them with a salt bath before toning. He was not in the position of never having faded prints, but he quoted an instance of prints made in 1861 and 1862 on evil-smelling paper that had not faded.

Dr. Thresh had taken advantage of the specific gravity of different solutions of hypo to ensure complete fixation, and believed that the lower specific gravity of a hypo bath used after one of a higher strength had ensured complete fixation. Washing prints by the dialytic method had eliminated all that could be got out in ten to fifteen minutes. If a sulphur compound was left in a print, he did not see why it should not be regarded as permanent, in support of which he quoted experiments made on sulphur-toned prints to test their permanency.

Mr. Haddon, in the course of his reply, recommended running water for the washing of prints, the latter to be separated. He agreed with Mr. Bothamley that hypo was probably not the cause of fading, but rather silver left in the high lights. He doubted the utility of Dr. Thresh's method of using solutions of hypo of different strengths, and concluded by remarking that he shortly hoped to give a paper on the influence of the strength of hypo used.

In moving a vote of thanks to Mr. Haddon for his paper, which was cordially passed, the President observed that that paper was a

very valuable one. The only perfect albumen prints he knew of had been washed in a pie dish for half an hour; but, in those days, pure albumen and pure paper were used.

The National Association of Professional Photographers, many members of which body were present at the Convention, also held a meeting in the evening.

Wednesday.

The General Meeting and the meeting of the General Committee were held in the Philosophical Hall. It was decided that next year's Convention shall be held at Great Yarmouth.

After the meeting, a group of the assembled members was taken at the Yorkshire College by Mr. Donald McIver, of Bond-street, Leeds.

Thursday's excursion was to York, and Mr. C. H. Bothamley read a paper on *Orthochromatic Photography*. To-day (Friday) Ripon, Studley Royal, and Fountains Abbey are to be visited, a Council meeting being held in the evening. The Convention meeting concludes with a visit to Knaresborough, Harrogate, &c.

OUTSIDE STUDIO WORK.—III.

Among the numerous outside commissions a photographer is asked to undertake, there are none perhaps requiring more skill and patience than the photographing of animals, and a by no means uncommon example of such work is found when dealing with horses, the owners of which, having very crude ideas of photography, often request the photographer to take such animals going at their fastest possible speed, either in trotting or galloping, as the case may be, for in these days of instantaneous photography it is considered an easy thing for a photographer to take a horse going at full gallop, when trains travelling at the rate of sixty miles an hour are photographed; and who has not heard of the marvellous results achieved by Muybridge and others, of which many people have read but evidently never seen examples?

There is no doubt much misconception exists on the part of the public generally as to the limits of photography when dealing with subjects in rapid motion, and even numbers of photographers could be found who have but a poor idea of the difficulty, if indeed not impossibility, of photographing a horse going at full gallop, provided anything like a reasonable size of image is to be the result.

As to the productions of Muybridge, these, no doubt, served the purpose for which they were intended, viz., to depict the various motions a horse developed in the act of galloping, but it is going too far to call such results pictures, for they were merely silouhettes, and such results would certainly not he accepted as satisfactory photographs by the owners of horses generally, who look for the results showing the utmost amount of definition possible.

Others, again, point to horses jumping over hurdles, and say, Look at that, how easily that is done. Yes; but there is a wide difference between a horse taken at the moment of jumping a hurdle and when the same is distended at full gallop shortly before rising to the leap; and, if any one doubts this assertion, let him proceed to test the question by exposing a plate on both situations, when he will get his eyes opened, no doubt.

The fact, is that to obtain a fully exposed image of moderate dimensions, say, even up to five inches in extent, of a horse going at full gallop, in such a position as will show the animal's four legs and his tail cut clean and sharp with a fair amount of definition and detail in the eyes and other portions of the body, is a feat but seldom achieved, and no one knows the difficulty better than those photographers who are in the habit of making a special study of animal photography, any one of whom, on being asked to undertake such a commission, will think twice before guaranteeing to do so with any hope of success, and any workers who have never had a try at such a job should be careful before undertaking such a difficult feat.

I know quite well fast shutters can be made to do a good deal in conjunction with fast plates, but I am not now referring to small-sized toy images, such as are taken by quarter-plate cameras. I am speaking as to the production of images direct of a fair amount of size, say, on plates up to whole-plate dimensions. Others, again, know the secret of so placing the camera as to take a rapidly moving object from such a standpoint as will almost blind off any appearance of rapid motion, such as the taking of a train or a bicycle, end on, and, no doubt, this dodge holds good to a certain extent when dealing with horses; but such results never satisfy an owner who require the action of his animals shown. It is this dash or action that is so much desired, and it is this dash or action that is so difficult, if indeed not impossible, to obtain. At least, if there are examples of such, I have never seen them, of any considerable extent as to size, when taken from such a standpoint as will depict the horse's four legs and tail with all the rest of the image well defined as to detail.

Sometimes one meets with very clever photographers who know a great deal and who have done this sort of thing often, but, on being asked to do it again, or even to show any of their boasted productions, they slink into obscurity.

I am not writing of such images as silouhettes or of very small images taken with short-focus lenses at a fairly long distance, I am referring to a direct picture of sufficient size to form a half-plate or whole-plate photograph when mounted.

There are, however, examples of a less exacting kind which, although somewhat difficult of execution, are not by any means verging on the impossible, in this class of subjects we have trotting horses or horses moving rapidly in vehicles.

In undertaking work of this kind, where the image is required of even a moderately fair size, the best of light, quick plates, and a shutter set for a high rate of speed are all necessary. Practice beforehand on a similar subject is also beneficial, because it enables an operator to learn exactly the proper amount of tension to set upon his shutter; if the shutter is driven too rapidly, loss of definition or detail will follow; if too slow, of course movement in the image is the necessary consequence.

A few trials at a well-selected standpoint are of great assistance, it not only enables the exact speed of the shutter to be ascertained, but it also helps the driver to do his part of the operation properly, for a good deal more depends upon the driver than many imagine, working at such close distance the sharpness of the image is very liable to suffer if the horse and vehicle are not led exactly over the chosen spot focussed upon.

To give anything like an idea of the speed a shutter should be worked at for such a subject as a trotting horse is in my opinion quite useless, the only way to arrive at such is to practise well beforehand.

I believe a great deal of misconception exists regarding the speed at which it is claimed some shutters work, and I know also that shutters are driven frequently far faster than there is any need for in instantaneous work. The movement or blurring perceptible in a negative of a moving object taken with a fast-working shutter is often caused by the vibration of the shutter, and not by the want of speed at which the shutter was working; with some shutters, to obtain high rates of speed, increased tension in the springs is required, and this, of course, means a firmer grip on the release clip, with the necessity for a consequently greater power or pressure to release the same. In nine cases out of ten, this extra pressure required to release the grip of the shutter causes a distinct kick or vibration at the most critical time in its use, just at the moment of exposure (I'm not speaking now of toy apparatus), but of such as are required for fairly large commercial working, and this is a fatal fault in all shutters which are liable to it. Many years ago I realised the importance of this, and discarded the use of several shutters in which this preparatory kick was apparent at the moment just prior to exposure.

I set about therefore to design and make a shutter that was free from such defects, and, although the one I use is quite a home-made article, made out of a common cigar box in fact, I have yet to see another that is better for any very fast work, or that will yield a better illumination of the foreground. Sometimes I smile when I am out working at the astonishment depicted on the faces of amateur workers, who evidently consider my flaps quite an antediluvian production, when compared with some of the modern highly polished articles but I know the value of a good shutter, and, although the one I use resembles old Toole in one of his inimitable characters, when he says, "You will find me a rum un to look at but a good un to go," I prefer it for several reasons to any I have hitherto seen, one of these reasons being that I have two release movements attached to it, whereby I can use it either right or left in accordance to the direction the object is travelling; by this means, should there be any kicking, the same follows the direction of the object, and tends to prevent any signs of movement of the object in the negative; there is more in working a shutter after this manner of dodging or chasing than many imagine when very high pressure is being used for fast speeds.

A close scrutiny of a negative in which there is blurring or movement of a moving object will often reveal the fact that such blurring is caused by an up-and-down motion, even in cases where the object has been travelling *across* the plate; this defect is clearly attributed to the kick of the shutter, and, as I have said, in nine cases out of ten is caused by the pressure on the release clip being too great.

T. N. Armstrong.

IMPRESSIONISM AND REALISM: THEIR SCOPE AND LIMITS IN PHOTOGRAPHY.

Six years ago an attempt was made by Dr. Emerson to show that what he called the naturalistic school of painters was the only true school of art, and that photography, being closely related to such a style of painting, was thereby raised not merely to the position of an art, but to the full dignity of a fine art. This contention caused a storm in a teacup. Discussions arose in every direction on the relation of photography to art, its limitations, and how far it was capable of rendering a naturalistic or impressionistic view of nature, Dr. Emerson and his followers asserting that photography is an art in the highest degree, capable of revealing in works the mind and personality of the artist, and by certain modifications able to yield effects even to the extreme of impressionism. Their opponents, of course, took up the opposite position to this, denying art in any form to photography, degrading it to the merely mechanical, arguing that the artist could not impress his mind upon such material, and that it was a purely imitative process, its only merit being the exact reproduction of minute and intricate detail which had no claim to the title of art. The theory started by Dr. Emerson he has since renounced, withdrawing from circulation his book on *Naturalistic Photography* in which it was put forth. He now denies art to the products of the camera, excepting in a very narrow sense. This conflict between the two sides continued for several years. The naturalists exhibited in various galleries some of their pictures, in which they embodied the principles of art they believed and taught. So marked was the individuality of their works that they became a class apart from the orthodox photographers, this fact alone showing that in some particular or method of working they departed from accepted canons, and proving their contention that personality can find expression even in a photograph. Lately, however, the vigour of this controversy has somewhat abated, breaking out only in an occasional article in the journals from some extremist on one side or the other. Now that the heat of the conflict has passed away, time having been given for ideas to mature, to settle in the mind, and for new thoughts to adjust themselves to the old, it would not be without interest to endeavour to draw from the controversy its lessons, if any, and try to discover the exact position in which it has left photography. To determine if it has had any material effect on the artistic development of photography, if it has modified the opinion generally held respecting its artistic merits, has strengthened or weakened its claims to be looked upon as one of the fine arts.

Impressionism.

It will be well to obtain at the beginning a clear and distinct idea of what is meant by such terms as "naturalism," "impressionism," "realism." This is not so easy as would at first appear, the terms used in art not admitting of that exact definition which is possible to science, the real significance of a word being often missed when defined too closely. However, I shall attempt it by giving, first, the definitions of men who speak with some title to be seriously considered by photographers; and, secondly, by reference to paintings and photographs in which the different methods are displayed, the latter means being at once the most delightful and instructive.

In general, the naturalistic and impressionist school are regarded as one and the same, and so Dr. Emerson in his first book classes them together. He observes:—

"But, as we have said, we regard the terms 'impressionism' and 'naturalism' as fundamentally synonymous, although we think the work of the so-called modern 'impressionists' but a passing craze."

In his latter writings Dr. Emerson cancels this opinion, and distinguishes very sharply between naturalism and impressionism. Thus:—

"Naturalism—the more or less correct reflection of nature, wherein truth of sentiment, illusion of truth (so far as possible), and decoration are of first importance."

"Impressionism, which is a purely personal vision of nature, as thus: An impressionist may paint sharply, or may paint colours wrongly from defect of vision, as does Monet."

Naturalism thus becomes a mere reflection of nature, whilst impressionism is a vision, an impression seen through the mind of the individual. For our purpose we will leave this refinement on one side, its evident purpose being to exclude photography from art, and return to Dr. Emerson's first work, where, regarding naturalism to include impressionism, he defines it thus:—

"Naturalism. By this term we mean the true and natural expression of the impression of nature by an art;" or, again,

"This, then, is what we understand by naturalism, that all suggestions should come from nature, and all techniques should be employed to give as true an expression of nature as possible." And he adds: "We prefer the term 'naturalism,' because in the latter the work can always be referred to a standard—nature."

According to these quotations impressionism means unfailing fidelity to nature; no very new claim as the standard of a school of painters; in fact, many in the past, and not a few in the present, uphold the same ideal. Schools have differed, not in their aim, but in their interpretation of nature. What is a true expression of nature? This is the real question. Thomas Bedding, however, denies the impressionists the right to this claim, and he sums them up in no measured terms as follows:—

"On the whole, from the foregoing illustrations, it may be deduced that impressionism cares nothing for truth; that it follows the imagination wherever it turns; that it seeks to know no amenability to intellectual discipline; that it is, in fact, the expression of unbridled licence, an eager yearning after the new, the strange, the grotesque—after anything or everything which has in its composition something in the nature of a revolt against generally accepted forms and ideals."

This is a strong condemnation, denying what Dr. Emerson especially claimed for impressionism, its truth to nature. H. P. Robinson, on the other hand, freely admits the fidelity to nature, but questions the possibility of including the whole of art within such bounds. He says: "There are those who look upon art as consisting entirely of a truthful representation of nature, modified by the moods and caprices of the artist, and believe that it is a matter very greatly of tones and colours, and that, above all, it should not teach or tell a story, or be in any other way interesting than as being an expression of the impression of the effect of a scene on the eye of the artist at the first glance. This particular sect is small in number, but loud in assertion, and protests that all art is worthless which does not use nature in a particular manner, according to a peculiar optical theory of its own. These sectarians have dubbed themselves 'naturalistics,' as though they absorbed into themselves all nature; but an examination of their works and doctrine will show that their claims as nature-worshippers extends to a very small part of the universal mother."

The foregoing should be carefully considered, coming, as it does, from a man who has done more than any other to demonstrate the powers of photography as a fine art. The final paragraph, as I shall try to show later, is a true estimate of the impressionist. The last definitions I shall give are from George Davison, a follower of Dr. Emerson, who upheld the principles of impressionism against the Doctor when he made his famous renunciation of naturalism and all its works.

Davison says: "In art the same influence is discovered in the revolt against conventionalism, and in the scholarly practice of those painters who have been variously called impressionists, naturalistics, and the like. It was such a return to nature, such a close observation of natural appearance under the influence of the materialistic tendency of the age, that led to the growth and practice of the body of painters known as impressionists. A more judicious section—those who seek a natural and scientific basis for their practice—has preferred, as far as such tenets permit any crystallisations, to style itself 'the Naturalistic School.' Finally, truth to nature is the first article of their faith, and the truest that science teaches concerning light and colour, and the manner in which the eye sees is made a guiding principle."

From these various statements of the meaning of impressionism it may be gathered that the impressionist strives hard to give an exact representation of nature. He makes the sensation caused by a scene upon the eye at a first glance the guiding principle, and disregards all the conventions or rules of art that have been practised by previous artists. More than this we are not justified in extracting from these writers' definitions. By such statements they have missed the true inwardness and meaning of impressionism, and added that which is not essential. The first point is in no way the special mark of impressionism, and the second has been previously discussed by artists. Burnet dismissed the doctrine as neither nature nor art. Hence, if impressionism means no more than these definitions imply, it contains no principle which separates it from other schools, unless it be the negation of all previous rules of art. But we see in its results a marked positive quality, and for this effect there must exist some adequate cause. This cause, and the real meaning of impressionism, the more easily to show its bearings on photography, I will proceed to unfold. For this purpose we will follow the second method of illustrating from pictures, taking as examples two paintings of the naturalistic school in public galleries that all may study. The one, mentioned favourably by Dr. Emerson is at South Kensington, *Carnation Lily; Lily Rose*, by Sargent, at present hanging in a badly lighted corner, and very difficult to study. The other is in the National Gallery, *The Harbour of Refuge*, by F. Walker, a painter commended by Dr. Emerson in his naturalistic days.

Things may be pictorially reproduced under several aspects, as colour, form, light and shade, and likewise as stationary or in motion, meaning by motion a change of light, as a sunrise or a sunset, the movement of bodies, the vitality of plants, the activity of animals, and the life and mind of man. This phase of motion is not generally brought forward in connexion with art, for reasons to be given later. The predominance of one or the other of these several aspects in a work of art will determine the character and position of a painter. Thus, the pre-Raphaelites are an example of a school of artists who painted chiefly the colours of bodies, subjecting all in their pictures to the scheme of colour. Ruskin says of Rossetti, that he could conceive in colour only. The Dutch painters were also largely dominated by colour, form took a very important place, and they excelled in the subtle rendering of light and shade, yet they lack something. In Rembrandt colour and form are feeble, but in their place we have a masterly management of light and shade.

Coming now to motion, there was no European school who could be said to represent the domination of motion in their works, until the birth of the modern impressionist, and they, I maintain, subordinate all in their pictures the better to suggest the idea of motion. There exists, however, a non-European school of painters who have attained to perfection in their skill of representing motion, and that is the Japanese. It was, no doubt, largely from the study of Japanese art that the modern French impressionists gained their ideas. Many of the Japanese studies of birds and flowers, meagre as they often are in detail and wanting in colour, have more of real life in them than any of the carefully painted Dutch flowers and fruit, with their faithfully represented flies and drops of dew. Motion is the something missing from Dutch art. They were content to paint dead birds, the Japanese strive to paint them living. This effort to suggest motion with another characteristic, to be discussed below, springing from their revolt against conventionalism, separates the impressionists from any school which has preceded them. The orthodox painter follows the teaching of Lessing, that objects in motion cannot be represented by painting; or, in his own words, "the painter can only create a presumption of motion; in reality, however, his figures are without motion." This is true when comparing the power of suggesting motion possible to painting and poetry respectively; but, when considered alone, painting can, and does, represent motion in a large degree, mainly by suggestion to the imagination, and likewise by deceiving the eye.

Now, the impressionist claims to represent bodies as they strike the eye of an observer at a first glance. The first notion of sight to engage the mind is not colour, form, light and shade, but the motion of bodies. Hence the impressionist is constantly striving to give this idea full expression, and neglecting colour, form, and light and shade. To support this contention that motion is the primary effect on the mind in sight, I will recall the well-known case of the boy who was born blind, and, by an operation in after-years, received his sight. When asked what was his first impression on opening his eyes, he replied, "The things jumped up and struck me." A passage from Addison will also show this attractiveness of motion, a passage interesting to photographers, as it gives a beautiful description of a picture formed by the camera obscura: "The prettiest landscape I ever saw was one drawn on the walls of a dark room, which stood opposite on one side to a navigable river, and on the other to a park. The experiment is very common in optics. Here you might discover the waves and fluctuations of the water in strong and proper colours, with the picture of a ship entering at one end, and sailing by degrees through the whole piece. On another there appeared the green shadows of trees, waving to and fro with the wind, and herds of deer among them in miniature, leaping about upon the wall. I must confess the novelty of such a sight may be one occasion of its pleasantness to the imagination, but certainly the chief reason is its near resemblance to nature, as it does not only, like other pictures, give the colour and figure, but the motions of the things it represents."

Motion or life, then, is what the impressionist is trying to represent on his canvas, and he subordinates to this aim colour, form, and, in a less degree, light and shade. This can be still further shown by considering in what manner, and how far, the impressionist is successful in reproducing inanimate bodies, say, a vase. Compared with the Dutch painters, he totally fails to give a complete or adequate impression of the vase to the eye or mind of the observer. The impressionist creates nothing but a vague and confused idea of such an object, and he turns instinctively to bodies upon which he can exercise his skill, living things and things of motion.

The second essential of impressionism, which divides it from older schools, and marks the rupture from the conventional, is the recognition of tones and the correct rendering of near and distant colours. Here it breaks away from all established rules, the tricks of older painters, and endeavours to represent colours, not as they are in the objects themselves, but as they seem to the eye of an observer. Such a recognition of colour values is a distinct advance in art, and a disavowal of the methods of the pre-Raphaelites who painted in colours of one value, totally ignoring the atmosphere and other conditions that alter the relative values of colours. The impressionist admits no rules to regulate the management of colour, and light and shade in his pictures, but paints directly from nature.

Examining next the pictures in which these principles are worked out, it can be readily noticed that they are painted exactly as might be expected to bring out most fully the idea of motion, and the doctrine of tone and colour values. Both pictures express motion, not in detail, but throughout the whole subject. That is, they show a falling light, a sunset, a movement from light to dark. A falling light is the simplest kind of motion that can be pictorially depicted, and it is instructive to notice that both artists have chosen the same subject. In Sargent's picture there is a second motion, the struggling of Chinese lanterns to overpower the dusk. It thus depicts at the same time a rising and a falling light.

The *Harbour of Refuge* represents the two sides of a square of those small almshouses so common in the country. A stone figure on a pedestal occupies the centre of the background, standing out against the red bricks of the building. On a seat at the base of this pedestal are some very old men, idling, driven from the storms of the world to their last refuge, spending their few remaining days in calm. In the foreground is a muscular young man, mowing the grass, behind him a may tree in full blossom. On the other side two figures parading a moss-covered walk, the one a woman in the prime of life, leading the other, a tottering dame bent double with age. Such is the picture; a subject which in ordinary hands would yield little. The first and only strong impression on looking at this picture is that it is evening, and not only evening, but that the sun a few moments before went down behind the row of cottages in the background. The very time of the day could be named so subtly is the failing light rendered. So perfect is the illusion that a prolonged look at the picture causes in the mind the same pleasant, melancholy emotions which sunset produces; in fact, as we gaze on this work of art, we can feel the shades of evening slowly falling.

On looking into the picture it drops to pieces. It must be viewed as a whole, the drawing being subordinated to the general effect. This can be readily seen by close examination of the mower in the foreground, the one figure in the picture in violent action. No detail can be traced in his dress, the folds and creases melting one into the other; yet, at the same time, they flow in the direction of his movement. The result, obtained by a sacrifice of detail, gives a good idea of the man's action. A Dutch painter, delineating the same subject, would have painted with great pains every crease and fold in the man's dress direct from nature, the result being a wooden formal thing, stood up to be painted. The Dutch seemed to recognise this limitation of their style, and they seldom show things in motion.

Another feature to notice, bearing upon the colour values, is that the picture is without those heavy shadows and masses of black so common in the older schools of painting when reproducing a sunset. But, in spite of this lack, the effect of evening is quite natural, proving that the addition of shadows by older painters was but an artifice, and not grounded on observation.

A third feature, showing how Walker must have studied from nature the value of his colours, is the brightness in which some of the objects are painted. Thus, the may-tree blossom is pure white, the colours of a border of flowers in the shadow of the cottages are also bright, and a tube holding a plant is painted a mid-day green. This brightness of colours amidst the shades of evening is a very noticeable phenomenon, flowers always appearing unusually bright in a dull light. Walker must have discovered this fact, and taken advantage of it to brighten the illusion he wished to create.

Sargent's painting is of a simple subject; it represents two children, robed in white dresses, occupied in a garden lighting Chinese lanterns, and suspending them amongst the lilies and laurels. At a first glance you fancy they are attending to the family washing, the next impression is somewhat confused, the eye failing to rest or to be led up to a prominent part of the picture; at last there comes an impression of greyness, it suddenly strikes the mind that it is evening, it is almost dark, and the lanterns are struggling to overpower the dimness and indefiniteness which prevail. The confusion, the indistinctness, the greyness which are the peculiar qualities of objects seen in the dusk, are seized upon and well rendered; the subject is likewise arranged in a manner to increase

the illusion, the lanterns faithfully recording their struggle to extinguish the dying light of day. Of beauty of form, or even form, in this painting there is none, the only attempt at graceful outline being the figure of the child in the foreground. On a closer scrutiny all detail and outline melt away; a conception of the picture is not possible without viewing it from a distance and as a whole. This picture likewise has none of those heavy shadows we associate with paintings of evening, in fact the black stockings of the child partake of the general greyness. As we look on them, the children, lanterns, and lilies appear to sway and vibrate, and produce on the mind a strong sensation of motion throughout the whole there is an appearance of life and of vitality which is very striking.

From the foregoing it may be deduced that the most prominent features of these paintings are: (*a*) the lack of detail, (*b*) the impossibility of taking a part away from them, (*c*) the general weakness of form and outline, (*d*) the representation of dusk by middle tones instead of dark tones, (*e*) the extension of the falling light through every part of the subject.

Lack of detail, and weakness of form and outline are the first necessities of the impressionist; and in the photographic school these traits are most marked. Fuzziness is forced upon the impressionist because by that method alone can he express the greatest amount of motion in his production. In the old numbers of *Punch* the wheels of a moving cab were represented by a number of radii taking the place of the spokes. This artifice was fairly successful. It had the defect of making the wheels go and the cab stand still. The impressionist, taking up this method, simply extends it, and carries it on through the whole of his picture. Such a plan is the only one by which motion can be suggested to the imagination by the eye. To paint a body in motion with sharp outline and minute detail is fatal. At South Kensington is a picture of this class called *Disturbed*, a bird on the wing just risen from a nest, it is nothing but a stuffed one, suspended in mid air, and we unconsciously look for the wire which upholds it. Turner recognised this necessity in his *Great Western Railway*, but he went too far and destroyed the actual structure of his subject.

JOHN A. RANDALL.

(*To be continued.*)

A SIMPLE METHOD OF STRIPPING GELATINO-BROMIDE PLATES FOR USE AS FILM NEGATIVES.

[Photographische Correspondenz.]

STRIPPING plates are to be had commercially, but they have certain drawbacks (the film often comes off in development), and generally they must be ordered in advance. In consequence of this, for a considerable time ways and means have been thought of for stripping an ordinary dry plate, without special preparation in the manufacture. As an example, we may mention treating with hydrofluoric acid, a plate tanned with alum; but the film must be transferred to another plate, and is often distorted, as the gelatine expands unequally, notwithstanding the hardening process.

Fluorides and citric acid are, however, better.

Hill & Barratt obtained an English patent for a method of stripping gelatine films from glass. For this purpose they used a mixture of

Fluoride of soda	1 drachm,
Citric acid	9 drachms,
Water	7 ounces,

in which the gelatine negative was dipped. But there is considerable expansion of the film, and it increases with the amount of citric acid in solution. Consequently this method, otherwise very useful, is open to objection. A method of preparing film negatives from ordinary dry plates has been worked out by M. H. Reeb, of Paris.

As means to this end he sends out two colourless fluids: "liqueur infaillible," and a collodion "collodion infaillible," contained in yellow bottles of 90 grammes, and 300 grammes.

M. H. Reeb's process, for preparation of a film negative from an ordinary dry plate is very simple and gives good results. We have had the opportunity of using it frequently.

The procedure is as follows, according to the instructions sent out with the preparations:—

1. Soak the gelatine negative in the "liqueur infaillible." The object of this operation is to destroy the adhesion of the gelatine to the glass.

One part of the "liqueur" is diluted with nine parts of water; in this the negative is soaked five to ten minutes, then drained and dried. It matters not if the negative is wet or dry, intensified or not intensified, retouched or untouched, provided that the retouching is insoluble in water.

2. Coating the film with "collodion infaillible."

The negative, after having been treated as above with the "liqueur infaillible" and dried, is placed on a levelling stand in a horizontal position and coated with the "collodion infaillible." For this purpose seven cubic centimetres are used to cover 100 square centimetres (about sixteen square inches).

The collodion is allowed to set perfectly, when it turns a dull milky colour, which passes over to a uniform blue. When it has reached this stage, the negative is well washed and the film is cut through round the margins, with the edge (not point) of a sharp knife. The cut should be made at one or two millimetres from the margin. After drying the film with filter paper, pressed down with an indiarubber roller, which will remove all superfluous moisture, the stripping can be performed with ease. The film is then transferred to the following glycerine bath:—

Glycerine	50 cubic centimetres.
Alcohol	50 ,, ,,
Water	1000 ,, ,,

3. Drying the films.

The film is dried on the glass from which it has been stripped, but with the collodionised side next the glass. For this purpose, the glass is cleaned by sponging with a little of the diluted glycerine bath, the film is then laid down upon it, whilst still dripping wet from the glycerine bath, a sheet of filter paper is then pressed upon the film with a rubber roller in both directions, and the plate is stood up to dry spontaneously. The film then loses its milky appearance.

The dried film, whilst still on the glass, is again coated with thinned "collodion infaillible" (one part collodion to two parts ether and alcohol) and drained.

If oily drops appear on the surface, they may be removed with a wad of dry linen or a little diluted alcohol. The dried negative is again cut through at the margins, stripped from the glass, and preserved flat between sheets of paper. If there is any difficulty in stripping, the plate is placed in warm water (40° C.), when it will come off directly. Dry between two drying boards under slight pressure in a copying frame.

The process we have just described is very good and practical, and would, doubtless, be very welcome to all if the price of the materials, which Mr. M. H. Reeb has placed upon the market was not so considerable. A small bottle containing 90 cubic centimetres of "liqueur infaillible" costs 2 frs. 50 c. A bottle containing 300 c. c. of "collodion infaillible" costs 4 frs. 50 c., according to the labels. For the worker these prices are too high. We have, nevertheless, introduced the process at the Imperial Technical Institute, and we have succeeded in making up both preparations, and we now find it very inexpensive.

As the matter interested me from the photo-mechanical as well as the chemical point of view, I investigated the composition of both solutions, the "liqueur" and the "collodion infaillible," with very satisfactory results.

The investigation showed that both the solutions in question were of rather simple composition. The "liqueur infallible" is a solution of formaldehyde, similar to that sold by Schering, of Berlin, under the name of formalin, whilst the "collodion infaillible" is an oily collodion, such as we meet with in commerce under the name of enamel collodion (plain collodion with two per cent. of castor oil). The experiments instituted with formalin and enamel collodion gave very good results, and, based upon them, I can give the following cheap and simple directions for the stripping of gelatine plates:—

Formalin	10 c. c.
Water	150 to 200 c. c.

The negative is left in this solution for ten minutes, then dried and coated with a two per cent. enamel collodion, or solution of gelatine.

In the first case, the treatment should be as already described for the "liqueur" and "collodion infaillible;" in the latter, the dry plate is treated as though it were a stripping plate, or a collodion emulsion plate. The plate is placed on a levelling stand, brought accurately to the horizontal, and coated with the following gelatine solution, in a slightly warm condition, to a depth of 2 mm.:—

Gelatine	75 grammes.
Water	500 ,,
Glycerine	10 ,,

Filter through flannel.

After the plates are set, they are set up to dry, and then coated with a much diluted negative varnish, or plain collodion, to protect them from damp.

When they are again dry, the film is cut through with a sharp knife and stripped from the glass.

The action of the formalin is that of an exceptionally good indurator; the film of the dry plate is hardened through and through, and does not adhere so firmly to the glass. It can consequently be stripped easily by means of the collodion or gelatine coating, which adds to the strength of the film. The process is uniformly successful, and gives very good results. For this reason, and because the cost of the chemicals places it within easy reach, I can especially recommend it to practical men.

E. VALENTA.

The Inquirer.

*** *In this column we shall, from time to time, print questions that may be addressed to individual contributors to our pages, or such as are sent to us with the view of eliciting information from a variety of sources. We invite the co-operation of our readers in rendering this feature of the* JOURNAL *useful and instructive.*

CHROMATE OF SILVER.—BILLERICAY writes: "Is it a fact, as asserted in this column last week, that an insoluble chromate of silver is formed by the action of bichromate of potash on carbonate of silver? I have treated a film of carbonate of silver in gelatine with bichromate, and the resulting red stain is entirely discharged by washing."

IODINE IN SOLUTION (To "Perplexed").—GERARD writes: "This correspondent, if he wants a strong solution of iodine, had better get the solution sold by chemists, and known as 'Lugol's Solution,' or he can make it himself. It consists of a solution of iodine in iodide of potassium, I forget the official strength, but that does not matter if the quantities used be noted, a solution of any strength can be made and diluted as required, as it mixes with perfect freedom with either water or spirit."

SOLUTION OF IODINE (To "Perplexed").—The tincture of iodine of the chemist is the handiest way of using the halogen, as if not added into too large proportion it mixes readily with water to form a solution strong enough for use on negatives or transparencies in careless hands. If a stronger solution be required, or if, as is sometimes the case with gelatine films, the presence of the spirit is objectionable, the iodine in crystals or scales may be dissolved in a solution of a soluble iodide, or in sal ammoniac, or nitrate of ammonia, all of which greatly increase its solubility. A plan that I have often found useful, when I have not had a soluble iodide or either of the other salts at hand, consists in shaking up the iodine with a solution of carbonate of ammonia or carbonate of soda until it acquires a sufficient degree of colouration. In this case a soluble iodide is first formed, and this then reacts upon the excess of iodine. When the solution, on being allowed to settle, shows the characteristic colour of iodine, it may be known that the iodine is in solution, and a very strong stock solution can be made in this way.—SYNTAX.

News and Notes.

THE PHOTOGRAPHIC CLUB.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock on Wednesday evening, July 22. *Halation, its Cause and Cure.* Visitors are welcome.

THE South London Photographic Society pay a visit to St. Albans on Saturday, July 25, by Midland Railway, St. Pancras, at 2.25 p.m., returning at 8.39 p.m., fare 1*s.* 9*d.* Tea at Clarendon Temperance Hotel, Cheqners-street. To all visitors is extended a welcome, and they are requested to address all communications to A. E. Allen.

ASSISTANTS AND THEIR GRIEVANCES.—A correspondent who had advertised for an assistant, and asked for specimens to be submitted, writes regarding the latter: "I should have liked you to have seen the contents of that package. I suppose it was from one of those very much oppressed assistants. It contained a quantity of soiled specimens, some of which must have been exposed for some time, torn away from backs out of show-cases."

GRIMSBY AND DISTRICT PHOTOGRAPHIC SOCIETY.—The following are the newly elected officers:—*President:* Mr. J. Sutcliffe.—*Vice-Presidents:* Mr. R. C. Long and Dr. Simpson.—*Committee:* Messrs. Hewitt, Tuxworth, Flint, Matthews, Wilmot, Brumpton, T. E. Gale, W. H. Marris, and Botterill.—*Librarian:* Mr. C. Dewing.—*Treasurer:* Mr. H. Dodds.—*Secretaries:* Messrs. John H. Clayton, 43, Tasburg-street, Grimsby, and William H. Marris, 118, Freeman-street, Grimsby.

"THE highly poisonous nature of acetylene has suggested to M. Chuard," says *Nature*, "the possibility of employing carbide of calcium as an insecticide for agricultural purposes. M. Chuard proposes to try thoroughly mixing the carbide with earth, so that, under the influence of moisture, acetylene would be slowly given off at the roots of plants, thus preserving them from attack. At the same time, the by-products, consisting of chalk and a little ammonia, would have a beneficial effect on the soil. It is proposed to try this method against phylloxera. Whether this would succeed equally well in all weathers, wet or dry, is quite another question."

RADIOGRAPHS WHILE YOU MOVE.—Mr. V. E. Johnson, M.A., F.R.M.S., sends us (*Daily Chronicle*) from Alderley Edge a couple of really admirable photographs of the bones of horse's knees taken by the Röntgen rays. He states that the apparatus used was a Grove's battery of six-quart cells, a ten-inch induction coil by Apps, and a focus tube by A. C. Cossor, together with other apparatus, concerning which he proposes to take out a patent; for the novelty of the idea consists in the fact that, as he declares, the horses were by no means still while the "skiagraph" was being taken. He even promises us that with the same device here used he will take photographs of any part of the human animal, not "while you wait," but "as you run."

KINETOGRAPHY.—We have received the following particulars relating to the De Bedt's Kinetograph for showing pictures in motion: The films are made for exhibition on the standard size Edison kinetoscope. They are fifty feet to 100 feet and 250 feet in length. The De Bedt's kinetograph takes pictures at the rate of five to eighty per second, and can be loaded with 100 feet of film. The same camera can also be used as an optical lantern for projecting the pictures life size on to a screen. The same camera can also be used as a kinetoscope. The weight of the De Bedt's kinetograph is ten pounds, the size is 8 × 8 × 6 inches. The price complete is 40*l.*, with a discount to the trade. The address is, The Anglo-American Photo Import Office, 368, Rue Saint-Honoré, Paris.

IN looking over old literature, I have frequently found many useful ideas, which, because of insufficient reflection, had not been thoroughly impressed on my mind at the first reading. For instance, a negative which has cracked without breaking the film may be made to print perfectly by painting the crack on the glass slide with a thin solution of balsam of fir and turpentine, using a small camel's-hair brush for the application. The balsam of fir unites with the broken edges, and, being transparent, nearly obviates the shadow which the crack would ordinarily cast. Or, in photographing hollow silver ware, you may fill it with ice water and make the negative as it begins to sweat, thereby getting rid of the glistening which would otherwise prove troublesome.—H. C. VOORHEES in *The Canadian Photographic Journal.*

MR. F. A. BRIDGE, who has just returned from another photographic tour in Norway, tells us of a very sad accident which happened there on July 4. An American gentleman and his wife, both provided with Kodaks, were being driven in a stolkjerre between Stalheim and Voss, when by the side of the beautiful and placid Opheim Lake there came up a pony which was being led from the mountains, its wooden paniers well filled with milk collected from the cows grazing there. Wishing to Kodak this (to them) unusual sight, they made a halt. A stinging fly had, unfortunately, settled on their own pony's neck; in its effort to shake off the fly, the pony somehow got the rein under the end of the shaft and then commenced to back, and, unfortunately, continued to do so until it had backed itself and its passengers into the lake. The "Gut," who had been driving, jumped off, but the lady and gentleman, being fastened in by the apron, could not release themselves, and when the bodies were recovered life was extinct. There were to have been grand doings at Stalheim that evening in honour of July 4, but all festivity was abandoned in consequence of this lamentable accident.

A COUNTY COURT JUDGE AND THE RÖNTGEN RAYS.—At the Liverpool County Court on Monday, during the hearing of an action under the Employers' Liability Act, in which a dock labourer claimed 150*l.* damages for personal injuries, the plaintiff's counsel produced two photographs of the injured arm taken by means of the Röntgen rays, which he proposed to put in as evidence. The defendant's counsel objected to them being received, and stated that he had no reason to believe that Dr. Buchanan, of the University College, by whom the photographs had been taken, was competent to produce reliable radiographs by the new process. Judge Shand said that, from all he had read concerning the process, he should himself be able to take photographs, providing he had the necessary apparatus. Dr. Buchanan agreed, and stated that it was perfectly simple, and could be done by any one. Judge Shand thought he must admit the photographs, but it would be open to defendant's counsel to address the jury regarding their value or otherwise. The photographs were then produced, and showed clearly the injury which had been done to the bone of the plaintiff's arm. The jury awarded the plaintiff 60*l.* damages.

GELATINE AND PHOTOGRAPHY.—There is one point in connexion with gelatine, and what it has done for photography, that must not be overlooked, though it would be more pleasant to do so if one could. It has rendered photography so simple that there is now very little indeed to learn in it. At one time there was, as in the collodion days, and when the user had to prepare his own paper, &c. As a consequence of this, as in all crafts where there is little to learn, the labour market is over-stocked, with the result that salaries have become greatly reduced from what used to be paid. As in the case of the *employés*, so with those who have businesses of their own; they have increased to such an extent that competition has become exceedingly keen in every direction, with the effect that prices are now so reduced that they are scarcely remunerative. That, however, is not all. There is now generally, in most families, one or more amateurs, and they obtain their material at much the same price as do professionals, so that the cost of everything used is tolerably well known to the lay public. Owing to this, reasonable charges for photographs are often looked upon as being extortionate. Looking at gelatine from this point of view, it is very questionable if it has proved an altogether unmixed blessing to professional photography.—E. W. FOXLEE, in *Autotype Notes.*

"MISCHIEVOUS ADVERTISEMENTS!"—No little of the contemptuous toleration which photography has to endure is directly traceable to the photographic community itself. First there are its workers, and then there are its dealers. The weakness of its workers is that many of them cannot defend their pictures. They find themselves in a false position. They have begun picture-making without knowing anything very definite about pictures, and when their work is attacked they are not sufficiently sure of their ground to endeavour to repel the assault. Others of them, who *do* know what they are aiming at, claim too much for their work, and, of the two, this is a more difficult position to defend than a claim of too little. Then, there are the dealers with those mischievous advertisements of apparatus—the magic apparatus that a child can manipulate without mistake—that produces its splendid pictures on the mere pressure of a button, the turning of a single screw, or the mere putting of a penny (the operator in *this* instance is required to make the intellectual effort of noting that a halfpenny or a button won't do) into a slot. Now can lying, even advertisement lying—which is considered to be the very perfection of the art—further go? Advertisement is useful—often it is a downright necessity—but it ought to be something approaching a rough approximation to the truth. When it is damaging alike to the dignity and worthiness of the pursuit out of which the advertiser seeks

to profit, and for the benefit of which he professes to labour; when it brings both his customers and the pursuit they follow into ridicule and reproach, it is mischievous, and stands self-condemned. The opponents of photography have made most effective use of these advertisements. In the face of them outsiders can *not* be blamed for looking upon photography as a pursuit not quite beyond simpletons and idiots.—G. E. MELLOR in *The Photographic Record.*

THE CAMERA CLUB.—The adjourned General Meeting of the Camera Club was held at the Club-house, as arranged, on May 28, for the purpose of electing Directors of the Company and Committee of the Club for the next twelve months. Some disappointment was expressed that arrangements had not been made for ascertaining the result of the "whip," some members being under the impression that it had been arranged to do this; this, however, was not so. There was a long discussion on various matters regarding the management of the Club, and a proposal was made to still further adjourn the election of the Committee, it being considered by some of those present that it would not be possible to decide as to the election of a Committee until it was known whether a sufficient amount had been subscribed to ensure that the Club would continue to exist; however, after further discussion, including a stirring speech from the Rev. Fitzpatrick, full of that *esprit-de-corps* which used to be such a delightful feature of the members of this Club, it was decided to proceed to the election, and the whole of the old Committee received the somewhat doubtful honour of re-election. A further meeting was called for Monday, June 22, and the meeting terminated about eight p.m. At this meeting the Directors were able to announce that the sum of 800*l.* had been subscribed, and that therefore the Club could be carried on without difficulty. Up to the morning of June 20, on which day the list was closed, 250 members had subscribed 676*l.*, this leaving 124*l.* still wanting to complete the sum of 800*l.*, which was fixed as the minimum amount required to ensure the continuance of the Club in future; at this juncture the Rev. N. R. Fitzpatrick, who had already subscribed generously to the whip, came forward, and, in a splendid spirit of generosity and loyalty to the Club, made a further donation of 124*l.*, so that the success of the whip should be put beyond all doubt. The Committee, feeling that a further effort should be made to induce more members to subscribe, proposed that the list be still kept open until the end of July, so that, if further subscriptions were received in that time, they might still be able to obtain the sum they required without taking so much from Rev. Fitzpatrick. This proposal was agreed to without any dissentients. It was then proposed that a statement of the present position of the Club and its future prospects, together with a short account of the past events, should be drawn up by some members of the Committee and posted to all the members, so that they might see the exact position of affairs, and also that those who had not already contributed to the whip might satisfy themselves as to the desirability of doing so. This also was agreed to, and then, after a few remarks from some of those present, the meeting was brought to an end by a very hearty vote of thanks to our Chairman for all the trouble and attention he had bestowed on the affairs of the Club. This was proposed in a short, but cordially worded, speech by Mr. Pringle, and seconded by a number of members in all parts of the room. Needless to say, it appeared to be unanimously agreed to.—*Camera Club Journal.*

THE ART OF PHOTOGRAPHING BIRDS' NESTS.—The genesis of the idea of illustrating a book on birds' nests from photographs taken direct from nature came about through my brother (who had already written and published a very successful book on birds' nests and egg-collecting), and finding the nest of a thrush one fine morning during a stroll near Enfield, in a very pretty situation, I remarked, "I'll fetch my camera and photograph that." "Right," he answered, "I'll find you some more nests for the same sort of treatment, and I'll write another book on the subject, which you shall illustrate for me by photographs taken in every case *in situ*." We accordingly set to work seriously, but for several reasons did not get much done during that season (1893). I think it well to remark here, that I soon discovered the fact that even with a bird's nest it was of no use to set up the camera and leave it to "make a picture" for itself. I sometimes spent an hour in examining a nest from all sorts of attitudes and points, in order to photograph it from the most picturesque point of view, and such time was, I'm quite sure, well spent, for it has trained my eye and considerably enhanced the value of the work I have done. At the beginning of my career I experimented with a variety of plates, but after a fair trial I finally selected Ilfords, which I now use exclusively, and have more than ample reason to be satisfied with. I use the hydroquinone developer, which I consider the best all round after an exteusive test, and the fair trial of others which I have used on the recommendation of photographic friends. My advice to beginners is, When you have begun to understand a good formula, plate, or camera, stick to it, if there seems to be any likelihood of getting good work out of it. The next points I would urge are care and patience. See that your lens is absolutely clean, satisfy yourself that you are going to take your picture from the best possible point of view either for picturesque effect or the showing of some particular part you desire to emphasise. Use every care to prevent your plate from "fogging" or your camera from vibrating whilst a negative is being exposed, get into a fixed habit of noting which plate was last exposed so as to avoid confusion, and the taking of one pretty picture on the top of another, exercise great care in charging and recharging your slides and developing your plates, pains, patience, and cleanliness pay, especially in developing and washing a negative. When out on a long day's work, I have a changing bag, which I am most particular to have carefully adjusted about the sleeves and face so as to avoid any chance of spoiling negatives and thus ruining pictures or the chances of making them. My brother, who is as thorough as a Teuton and as enterprising as a Yankee, always seconds me admirably in the exercise of care and completeness, and sometimes on a very bright sunny day I may be seen just stirring under a heap of garments, whilst he stands quietly by almost denuded of clothing. In photographing nests in grass, rushes, reeds, or low bushes when there is the faintest suggestion of a breeze blowing, my brother and I hold our jackets (sometimes top coats) so as to prevent the wind from shaking the foliage. We made ourselves a screen of green baize, with a sharp-pointed post at either end for running into the ground, but this we discovered to add too much to our impedimenta when making long journeys, so abandoned it. When photographing a bird's nest in bright sunlight, I have generally got my brother to shade the area around it by holding up his jacket or a piece of waterproof cloth in which I carry my slides. This entails a rather longer exposure sometimes, but prevents a nasty sheen (which is a difficult matter at all times to deal with, especially on highly polished shells) from destroying the markings of the eggs where the light strikes them. It also, to my thinking, produces a softer and better picture, although I have obtained some astonishing results (instance pochard's nest in *British Birds' Nests*) where I have been unable to shade the object under treatment. I have now obtained "a screen," at the urgent request of friends who swear by it, but I have not yet had sufficient experience with it to warrant me in saying anything about its advantages or disadvantages. In dealing with nests situated in high hedges, my brother generally borrows a cart (a tumbril is far better than a spring cart for the purpose) from the nearest farmhouse, and backs it into the hedge-row. I get inside, and whilst he holds the shafts I make a photograph. The nests of the hedge-sparrow, greenfinch, and blackbird appearing in my brother's book were all photographed in this way. In obtaining negatives of the nests of tree-builders such as the sparrow-hawk, carrion-crow, ring-dove, and others, I have climbed the tree in which they were situated, or another close by, and dropped the end of a long rope which I have taken up with me to my brother below. He has then attached the camera, and I have hauled it up hand over hand. This is an operation which needs considerable care, as the slightest swing or twist will often dash the apparatus heavily against some branch. When I have secured the camera, I lash the legs of the tripod to the nearest branches and commence to focus. It is generally a very difficult matter to arrange things satisfactorily for this sort of work, and I would earnestly advise beginners, who are not good gymnasts and have not steady heads on their shoulders, to exercise a great deal of care. I am, as a matter of fact, a trained gymnast with some ballooning experience, and feel just as much at home, photographing on the end of a rope with two hundred feet of "thin air" between me and the sea below, as I do standing on a garden path, but all the same I know the dangers of the work and appreciate them. Without any intention of in the least boasting about my own feats, I may mention that only the other day my brother and I affixed a ladder nineteen feet long on the topmost branches of a tree at least fifty feet in height. This was done in order to get a good look into a carrion-crow's nest, which is a very deep one, and obtain a picture with the eggs showing in it. As the branches to which the ladder had to be lashed were near the top of the tree, they were not very thick or strong. This necessitated the position of the ladder being absolutely perpendicular, as any angle would have caused such a leverage on it as to instantly snap the branches. After an hour or two we fixed the ladder up, and ascended and lashed the legs of my tripod thereto. Whilst focussing and preparing to take a photograph, I had a hand occupied on each side of the ladder, and, to prevent myself from falling backwards over, I was obliged to literally hold on by my teeth to one of the rungs. As an illustration of the time occupied in obtaining these difficult-to-come-at pictures, I may mention that the procuring of the above photograph cost us a full half day.—C. KEARTON in *Photographic Scraps.*

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK

July.	Name of Society.	Subject.
20.....	Bradford.....	*Intensification, Reduction, and Improvement of Negatives* P. R. Salmon.
20.....	North Middlesex	*Bromide Paper.* S. E. Wall.
21.....	Birmingham Photo. Society ..	Excursion: Dovedale. Leader, J. H. Pickard.
21.....	Brixton and Clapham	Ordinary Meeting.
21.....	Gospel Oak	Printing Dodges and Working up Negatives.
21.....	Hackney.....	*Fixing and Washing.* E J. Wall.
22.....	Photographic Club	Halation, its Cause and Cure.
25.....	Borough Polytechnic.....	Excursion: South Norwood, Addington, and Bromley.
25.....	Croydon Microscopical	Excursion: Horley. Leader, A. Roods.
25.....	Leytonstone	Cycle Run.
25.....	South London	Excursion: St. Albans. Leader, A. E. Allen.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JULY 9.—Mr. H. C. Rapson in the chair.

Mr. Edwin Banks was nominated for membership.

DARK-ROOM ILLUMINATION.

Mr. BECKETT thought it was a very common habit with photographers to work with too little light.

Mr. HENDERSON believed the time not far distant when they would find out what actinism really was, and how to counteract it, and that they would be able to manipulate in a light very nearly as good as that of day. He recalled a competition he had instituted years ago for the discovery of a light that would have no effect on a certain plate in a given time which he fixed, but which, unfortunately, elicited no response at the time, although, some time after its withdrawal, a method was submitted to him which consisted in perforating a doubled piece of card with pinholes, and then partially opening out the same, resulting in a sort of diffused light, which was said to be quite safe.

The HON. SECRETARY was in the habit of using a gas burner outside a window, constructed of a sheet of ground glass backed up with a brownish-orange glass, and one thickness of canary medium, which answered admirably. For orthochromatic work he had an extra ruby glass, but only used this extreme cases.

Mr. HENDERSON pointed out that different samples of canary medium varied in quality. The original, which was of a greenish-yellow colour, worked exceedingly well.

Mr. BULLEN said it could be got in any quantity at Marion's, and thought very few plate-makers were without it; in fact, the only time that bare glass was used was in examining the plates for spots and dust.

Mr. Bayston used an ordinary oil lamp provided with one thickness each of yellow glass and commercial orange paper. He found that plates exposed to this light for five, ten, or fifteen minutes at twelve inches distance fogged in every case, while, when exposed to a candle shaded by a piece of opaque material to prevent the direct rays from falling on the plate, and, at a distance of fifteen feet, very little, if any, effect could be found. With the former light, however, in developing, no ill effect was experienced.

Mr. Teape's experiments, which he had made very severe, pointed to Christia medium as the best substance for illumination he had tried, one thickness being superior to several of others.

The Chairman had had a contrary experience, an ordinary plate fogging very rapidly.

Mr. WELFORD thought the fact was overlooked that none of these media would stand a very extended exposure to sunlight without bleaching. He contended that the size of the window did not matter. With a larger window no more light fell upon the plate, but one could see better round the room, and so supposed the light stronger.

The HON. SECRETARY differed. With daylight the size of the window is certainly a factor, and one should regulate the distance of the sink accordingly.

Mr. BECKETT would like to know the definition of a safe light. Seeing that all light fogged plates, a window with one foot of area would be safer than one of sixteen feet. As to whether artificial illumination or daylight should be used, he would never use the latter again for developing by. The former was much more manageable and more constant.

PHOTOGRAPHIC CLUB.

JULY 8.—Mr. R. P. Drage in the chair.

Mr. GOTZ made his report of the result of the Club's first summer outing. He said that he had no cause to regret the trouble which he and his coadjutor (Mr. Stretton) had taken in connexion with the outing. Although the numbers present were not large, the company thoroughly enjoyed themselves—they had a jolly time and splendid weather. They were specially indebted to Mr. Stretton for the use of his boat. The feeding arrangements turned out satisfactory, and the trip generally was a success. He passed round a group of the excursionists. Another year Mr. Gotz hoped that a larger percentage of ladies would be induced to attend.

Mr. WELFORD—as one of the party—recognised the strenuous efforts which the organizers of the excursion had made. He moved that they be heartily thanked, and Mr. FOXLEE having seconded the proposition, and added a word or two in favour of Mr. Gotz's idea that ladies should be specially invited to attend on future occasions of the sort, it was carried unanimously.

The CHAIRMAN welcomed Mr. Tagliaferro to England and the Photographic Club.

Mr. Wallis handed in a sketch illustrating a new view-finder which he had seen. This device—which was recognised by several of the members present—was of the same type as the Heywood finder, viz., a metal frame and a sighting point. It was stated that, although useful for a fixed camera, it was not without objections from the hand camerist's point of view.

Brixton and Clapham Camera Club.—July 7, the chair being occupied by the President (Mr. J. W. Coade).—Alterations in the rule relating to the election of officers at the annual general meeting in January were considered and agreed to, and a special committee elected to arrange details of the forthcoming Exhibition, which will be held early in October next, and will include both open and members' classes, silver and bronze medals being awarded to successful competitors in each class.

A MEMBERS' excursion to Perivale and Greenford took place on Saturday, June 27. The attendance was not so large as might be desired, but the ramble was a most enjoyable and successful one, a result largely due to Mr. R. Whiting, of the Ealing Photographic Society, who kindly acted as conductor.

Croydon Camera Club.—The award of Mr. John A. Hodges, F.R.P.S., who was appointed to judge the lantern slides sent in competition for three prizes offered by the Croydon Camera Club to its members, has just been published. Forty-five entries were forthcoming in two classes. No competitor was, however, allowed to take more than one prize. In Class A (architecture) the prize (half-a-guinea) went to Mr. Hector Maclean for a "clean," forcible view of the half-ruined remains of St. Thomas's Church, Winchelsea. In Class B (any subject other than architecture) the first prize (half-a-guinea) was given to Mr. A. E. Isaac for a clever and striking composition of river, trees, and clouds, entitled *A Stormy Evening;* it is the least hackneyed of the landscapes submitted. Second prize (5*s.*) fell to Mr. H. E. Holland for an admirable scene on the River Teign, near Chagford. In this the colour and general technique are most praiseworthy, also to be greatly commended is the placid beauty of its subject.

Croydon Microscopical and Natural History Club (Photographic Section).—On Saturday a party of fifteen visited the remains of the old Roman villa at Darenth, Kent. This is situated about a mile from the Farringdon-road Station (L.C.D.R.), and is close by the old Roman road connecting Rochester and London. The excavation was first commenced in 1894, after a burial of probably 1500 years, although the site is marked on old ordnance maps. Crossing the field close to the station, the party proceeded by the high road as far as the mill pond through which the river Darent flows. Here several interesting botanical specimens were obtained by means of wading by an adventurous and enthusiastic member of the party. Among the plants found was the flowering rush, by no means a common plant. The path then skirted the banks of the river until the villa was reached. The remains are the most extensive yet discovered in England, and it is supposed that the villa was the residence of a high military officer of the Roman army of occupation. From east to west is an unbroken line of rooms and other enclosed places extending for 450 feet. In front of those to the south is a corridor of the same length. Beyond the corridor are two courts, ninety-two and ninety-one feet long, and seventy-eight feet wide respectively. Along the east and west sides of these courts a series of rooms extends for some distance. The centre of the house was occupied by the cold rooms for summer use. Three of these are paved with red tesserae, the remainder with concrete and tiles. Some of the walls are adorned with distemper painting, but the colours have now almost disappeared. The winter rooms are at the south-east corner, and the floors of the heated chambers were suspended in various ways. One was laid on piles of flat tiles, two others were supported on flue tiles, and a fourth on blocks of chalk in rows about six inches apart. Flue pipes still remain in the walls. The doorways of one or two of the rooms had been blocked in Saxon times with herring-bone work. The baths are situated at the west of the summer rooms, the largest being forty feet long and ten feet wide, and the walls are still four feet high. This was reached by four steps plastered and rounded at the edges, but at some time during the Roman occupation a wall had been built across it. Two small baths, about seven feet square, connected with rooms probably used for dressing, adjoin. There are several tanks at the north angle, originally fitted with leaden pipes, a portion of one still remaining. These communicate with a water channel discharging into a drain. At the southern and western extremities of the courtyard are the remains of stables and outhouses, the walls of which appear to extend into the field beyond. To prevent inundations, a wall, 340 feet in length, had been erected between the river and the courts. The foundations of the villa are now from four to five feet below the surface. Numerous antiquities have been found, such as coins, ornaments, knives, fragments of pottery and glass, and bones of various animals. The foundations of a small temple have also been discovered close by. From the fact that the walls of the adjacent church at Darenth contain many Roman tiles, it is supposed that the materials from the ruins of the villa were used in the construction of this edifice. Successful photographs, showing the hypocausts and other special portions of the villa, also a general view of the entire remains of the villa as now seen, were obtained by Messrs. Sparrow, Page, and Baldock.

Dulwich Photographic Society.—The members of this Society, on the 27th ult., visited Childwick Bury, St. Albans, the residence of Sir J. Blundell Maple, M.P., by his kind invitation. Some good pictures of the house and grounds were secured, after which the party were entertained to tea. The Society is now arranging a steam launch trip up river.

Ashton-under-Lyne Photographic Society.—On Saturday the Ashton amateur photographers and a few friends, to the aggregate number of forty-five, went on a day excursion to the ancient city of Lichfield for the purpose of taking views of its beautiful Cathedral. The party left Oldham-road Station, Ashton, at 8.10 a.m., and included, amongst others, Dr. A. Hamilton (President), Mr. J. W. Kenworthy (who acted as leader), Major R. Bradley, Rev. J. M. Craven, Messrs. T. Glazebrook, E. Hampson, J. Morris, W. Morris, S. Woolley, S. Sharp, T. F. Kershaw. J. Shaw, W. H. George, E. Belfield, W. Duckworth, J. Greenhalgh, J. H. Lawton, W. Marsland, W. M. Hyslop, H. Hurst, J. Jones, J. K. Greenhalgh, J. Taylor, J. Urmson, W. Leigh, J. Hutchinson, Mrs. Moores, and Mr. R. T. Marsland (Secretary). Lichfield was reached two hours before mid-day, and the party at once proceeded, some in conveyances and others on foot, to the one attraction of the city. In traversing the mile and a half or so from the station to the Cathedral, one got the impression that life moved slowly in the city, and this impression received ample confirmation—in the case, at least, of five unfortunate individuals—before the day was over. On arriving at the scene of operations, no time was lost in fixing the tripods and adjusting the lenses to the proper focus for taking exterior views of the building, the morning light being deemed the best for this. While the photographers were busy with their cameras, the rest of the party went on a tour of inspection. The Cathedral itself is an imposing structure, dating far back into the misty past. Outside, the most striking portion is the west front, in which there are three entrances. The doors are partially covered with old ironwork, the arches are so richly sculptured as to present quite a mass of foliage and figures, and, studded all over the extensive front, are other figures in bas-relief, representing the genealogy of Christ and of ancient kings and princesses, who have encouraged the growth of Christianity. Entering by one of these doorways, the steps of which are worn low by the incessant tramp of feet, what a change there was—what a contrast! Outside was the glare of a hot sun, and the animation occasioned by the fresh arrival of visitors; within, the atmosphere was deliciously cool, and the vast interior productive of restful calm. Dim shadows lingered amid the clustering pillars and away up into the lofty arches, and in deep recesses, where the eye tried in vain to separate formless objects from the surrounding gloom. One admired the amazing height and girth of the numerous ornate columns, wrought by cunning hands in a long-vanished past; the soft lights and shades were restful to the eye, and the solemn silence, disturbed only by the casual footsteps of visitors flitting hither and thither, as soothing to the spirit. Presently music, soft and sweet from the choristers chanting the psalms for the day, faintly broke the impressive stillness, and the music rose and fell in undulating cadences as one wandered to the extremities of the transepts, or in and out among the effigies—the mute monuments of departed greatness. At 4.20 the members and friends assembled near the north doorway, and were photographed in a group, and immediately afterwards an adjournment was made to a neighbouring hostelry, which, for reasons best known to the five individuals before mentioned, shall be nameless, where Mr. Kenworthy generously provided them with a splendid repast. At the close a hearty vote of thanks was passed to him, on the motion of the Rev. J. M. Craven, seconded by Major Bradley; and, a similar compliment having been paid to the Secretary (Mr. Marsland) for the excellent arrangements he had made for the day, the company betook themselves to brakes, which were in waiting to convey them to the station, and home was reached shortly after 8.30. The number of plates exposed was 300, and the number of cameras twenty-one.

Patent News.

The following applications for Patents were made between July 1 and July 8, 1896:—

Lighting.—No. 14,332. "Improvements in Apparatus for the Use of Electric Light, Gas, or Oil for Photographic, Illuminating, and other purposes." A. G. Adamson.

Automatic Photographic Machines.—No. 14,435. "Improvements in and relating to Coin-freed Automatic Photographic Machines." P. Mushet.

Screen Kinetoscopy.—No. 14,443. "Improvements in Apparatus for Producing Magic-lantern Pictures in Space and in Motion." E. S. Bruce.

Magazine Cameras.—No. 14,503. "Improvements in Magazine Cameras." J. J. Clipsham.

Sheath.—No. 14,560. "A Sheath for Holding Plates, Films, or Papers for Photographic or other Purposes." J. Airs.

Developing Tents.—No. 14,593. "Improvements in or relating to Photographic Developing Tents." F. Beresford.

Washing Apparatus.—No. 14,628. "Improvements in Washing Photographic Plates and Prints and in Apparatus therefor." A. Lehmann.

Photographic Apparatus.—No. 14,734. "An Improved Method of Extending and Collapsing Photographic and other Apparatus." A. C. Smith.

Lens.—No. 14,821. "Improved Optical Lens for Exhibition purposes." J. Walsh.

Screen Kinetoscopy.—No. 14,830. "A Camera for Taking Instantaneous Photographs in Rapid Succession, and for Exhibiting the same." J. Scotney-George.

Correspondence.

☛ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

"PHOTOGRAPHING IN THE NATIONAL GALLERY."

To the Editors.

Gentlemen,—In continuation of my last note, which you kindly published, I send herewith a circular from the Continental firm in question, *and which I readily obtained in the National Gallery.* In view of the fact that in the neighbourhood there are some half-a-dozen heavily taxed, rented, and rated printsellers who have spent hundreds of pounds in the reproduction of National pictures, it seems a strange proceeding on the part of the Gallery officials that they should permit the issue of this circular *within the walls* of the National institution. One of the said printsellers informed me that a lady entered his shop a few days since and expressed surprise on finding that he sold Gallery prints, she having been informed by a Gallery official that they could only be procured *as per circular.* This statement, as made by a reliable and respectable person, will be confirmed on oath if necessary. I think enough has been said to show the Gallery authorities that such extended privileges to *any* firm, much less to a foreign one, is calculated to breed trouble.—I am, yours, &c.,

J. Liddy.

34, *Tunley-road, Craven Park, N.W.*

Answers to Correspondents.

*** *All matters intended for the text portion of this* Journal, *including queries, must be addressed to* "The Editors, The British Journal of Photography," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* Henry Greenwood & Co., 2, *York-street, Covent Garden, London.*

Photographs Registered:—

Albert Randolph Douglas, 23, Upper Dicconson-street, Wigan, Lancashire.—*Two photographs of Royal Albert Edward Infirmary, Wigan, Lancashire. Size,* 15×12 *inches.*

F. Bird (Kingstown).—Letters returned. Please send your address.

Cinematograph.—W. H. writes: "Could you kindly inform me where I could get information about the Lumière cinematograph—the price, how to expose, print, and develop the films," &c.?—Write to Messrs. Lumière, Polytechnic Institution, Regent-street.

Transparencies.—A. E. Collings. Any ordinary water colours of a transparent character, such as are used for lantern slides. Messrs. Barnard & Son, and other artists' colourmen, we believe, supply colours specially for lantern-slide colouring.

Hand Camera.—P. O. Malley. The trouble is due to light getting into the camera. As the fog is always at the same corner of the plate, there should be no difficulty in localising the defect and remedying it.

Value of Goodwill.—S. J. and Provincial. It is quite out of our province to value photographic businesses; and, even if it were, it would be quite impossible to do so on the data supplied by either correspondent. Read article on the subject on another page.

Dark Slides.—S. J. If a very sensitive plate be left in a dark slide fully exposed to a strong light for a time, it will be fogged, and even show the grain of the wood and the form of the panels. No careful operator leaves his slides so exposed, as he knows what would be the result. Use more care in future.

Enamelling Prints.—Enamel asks: "Can you inform me as to the best method of enamelling albumenised silver prints?"—Space is too limited in this column to give the working details. Several articles on the subject will be found in the Almanac for the current and past years. Refer to these; they give full working instructions.

Mountant.—W. Wilson. Dextrine—that is, dextrine as found in commerce—is not to be recommended as a mountant for photographs, because it is almost invariably acid, and in this state might have a pernicious action on the picture. If the dextrine were pure, and free from acid, we see no objection to its use, and it would be a convenient mountant.

Albumenised Paper.—R. Ovenden. There is no very great difficulty in albumenising paper, though it requires some practice before proficiency is attained. As you only consume a ream or two a year, we can assure you that it would be false economy to albumenise your own. You can purchase it cheaper and better than that you would be likely to produce, if you have had no experience in the work.

Sensitising Paper.—Sensitiser writes: "I have some Double albumenised paper (cross swords) brand, which I want to sensitise; will you be good enough to give me instructions for same? I have an argentometer and some nitrate of silver by me."—Make up a solution of nitrate of silver, fifty to sixty grains to the ounce of water; place in a dish, and float the paper on it for two to three minutes, and dry.

Opalines Peeling off.—F. W. R. says: "I have done a quantity of opalines lately with P.O.P., and, although I do not harden the prints with alum, I find the greater quantity of them leaving the glass at the edges; and, as you cannot use the hot gelatine, could you advise me in any way?"—Coat the glass with a solution of gelatine, and let it thoroughly set. Then squeegee the print down upon that, instead of on the bare glass.

Photographic Paper.—T. Coombs writes: "Is there no cheaper paper than the Saxe and the Rives that will do as well for albumenising and photographic purposes generally? The price of these papers is simply extortionate as compared with the very best writing papers."—We know of no paper that answers so well. The manufacture of all the photographic paper used throughout the world is confined to two, or, perhaps, three, firms on the Continent. They have the business entirely in their own hands.

Lenses.—Captain Woolley writes: "I have hitherto worked with a half-plate Ross's rapid symmetrical, but am now desirous of getting a whole-plate lens for a new camera, and after reading your remarks in this year's Almanac, never having used an anastigmat myself, I am still undecided whether to have a rapid symmetrical or a Zeiss, Series IIa, which Ross says would suit me, as I like a long focus. Is it only a matter of rapidity that constitutes the principal advantage of the Zeiss?"—In reply: The anastigmats have the advantage over the older forms in freedom from astigmatism, while they give a flatter field and are more rapid.

Sale of Business.—Victim writes: "I can sympathise with your correspondent 'Sold,' replied to a fortnight ago. I, too, have been sold in the purchase of a business, for which I paid a good price. I have been in it now nine months, and I find that the takings are not more than half what they were represented as being for the corresponding months of the two previous years. In fact, there are no profits at all after the expenses are paid. Surely, there ought to be some remedy for this kind of thing?"—There is, if there has been a fraudulent misstatement as to the amount of business that was done. If that can be proved, the law will give ample redress.

Fading Prints.—W. G. H. The prints are certainly in a sorry plight, considering they are only a couple of months old. They are on board of a much commoner quality than is usually employed by professional mounters. It does not follow, however, that the mounts are the cause of the fading, because some common board is occasionally more inert on photographs than is some of the more expensive kinds. The only way to arrive at the cause of the fading is by a thorough chemical examination. A noteworthy feature in the case is that several of the prints have the imprint upon them of a foot rule. It would be interesting to know at what stage of the work this was used, what for, and of what material it is composed?

Faulty Dark Slides.—C. Wright writes: "I enclose a print from each of two negatives, in which you will see that they are fogged through the light getting through the wood of the shutters. You will see distinctly the shape of the panels, but no trace of fog where the flexible material of the hinge is. The plates were exposed in very bright sunlight, but the slide was not exposed to it more than could be helped. The shutters, when examined by direct sunlight, seem perfectly opaque. Have you ever seen such a case before?"—Yes, more than once. The shutters of some dark slides are much too thin for some of the very rapid plates now made if they are exposed for long to a bright summer light. Thicker wood means greater weight, and that many object to. The only thing we can suggest is to reblack the inside of the shutters, and protect the slides as much as possible from light when in use.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1890. Vol. XLIII.—JULY 24, 1896.

Contents.

EX CATHEDRÂ.

Mr. J. Howlett, of East Dulwich, writes to us with regard to a couple of Answers to Correspondents, in our last issue, on the subject of defective dark slides, that he was formerly troubled in the same direction, until he adopted a simple expedient that has proved a perfect remedy. Having frequently noticed, when working in the open air, in a strong light, that his plates were more or less fogged or veiled, except where the cloth hinge of the shutter crossed the plate, he came to the conclusion, as stated in our Answer, that the wood shutters were not sufficiently thick to afford adequate protection to the plates. He sent the slides to the maker, and had the whole surface of the shutters covered with the black cloth or drill, instead of merely a strip to form the hinges, and since that has never had a fogged plate; which reminds us that, some few years back, we saw a set of slides made by an amateur, the shutters of which, for portability's sake, were constructed of such thin wood that, in its unblacked and unprotected condition, it was quite translucent in a fairly strong light. But, for the double purpose of giving strength and opacity, the inner sides of the shutters were covered with stout black jean, the pores of the wood being first filled up by rubbing in lamp-black mixed with thin glue, the result being that the slides were perfectly light-tight. The remedy is for leaky shutters seems a simple one that might be taken notice of by camera manufacturers.

* * *

The same gentleman also sends us what he terms a "wrinkle" in connexion with sulphite of soda, suggested by a recent allusion to the anhydrous salt. He says, and we fully agree with him, that there is a vast amount of stuff sold as sulphite that contains but a very small proportion of that salt, the crystals, instead of being large and well formed, being small and mixed up with dusty powder. On getting such a sample, he says, "I sift out the dust and proceed to make a warm saturated solution of the remaining crystals. I then partly fill a glass boiling flask with the crystals, and cover them with the warm saturated solution, which is then raised to the boiling point by immersing the flask in a saucepan of boiling water, the contents being kept in motion by a gentle swirling action of the flask. When as hot as it can be got in this manner the liquid, after a final shake, is quickly poured off into a thin beaker glass, when it will be found to be milky or opaque from the presence of a fine powder held in suspension, which is supposed to be anhydrous sulphate of soda. This quickly settles down, and the supernatant liquid is poured back into the flask, and the boiling operation repeated until no more of the anhydrous salt can be extracted, or until a sufficiency has been obtained. If allowed to cool, after boiling, the white powder will redissolve, hence the necessity for pouring off the liquid quickly. In this manner I get even from the most suspicious-looking samples a product which in dissolving to saturation at normal temperature is far nearer to the correct composition of neutral sulphite of soda than the majority of samples sold as such, as can be proved by the barium-chloride test followed by hydrochloric acid."

* * *

This seems to be a very simple method by which, under unfavourable circumstances, a tolerably reliable solution of sulphite may be obtained. As met with in commerce, the crystals too often consist almost wholly of sulphate, but by taking advantage of the peculiar property of sulphite of soda of separating, in what is supposed to be the anhydrous condition from boiling solutions, the sulphate is altogether got rid of, and the powder that is collected proves itself by virtue of its separation to be sulphite. Another method by which the

sulphite can be obtained in the anhydrous condition—in which it is a more stable substance than when hydrated—is to keep it for some time at a high temperature, though this, of course, assumes a reliable sample of the sulphite to be selected in the first instance. If the ordinary hydrated crystals be submitted to a temperature of about 300° Fahr. in an ordinary oven or in a sand bath, they will lose the whole of their water of crystallisation, and become compact and glassy in character, and in this state resist oxidation far better. If a demand arose for the anhydrous salt, we have little doubt it would be met by those interested.

* * *

The most serious and sacred matters rarely escape ridicule, or, at least, travesty, and science generally, and photography in particular, are no exceptions to the rule; but, where the fun is good-natured and harmless, one cannot very well complain of it, as was the case with one of Albert Smith's lectures many years ago. In this he happily hit off the capabilities of the photographic lens in the way of distortion in a *Photograph of the Artist by Himself* which consisted of a gigantic hand. The explanation given was that, having to uncap the lens himself, it could not be expected that anything but his hand was visible. Equally good was the *View of Strasburg Cathedral by Night*, a mere daub of black, and the spectator who complained that he could not see the cathedral was met by the inquiry as to how he expected to see it *in the dark*.

* * *

Now the Röntgen rays have come in for their share. A short time back, at a private garden party where various amusements were introduced, a small tent was noticeable, with an announcement something to the following effect, "Come and see the 'Xtraordinary Rays! These extra ordinary rays must not be confounded with the ordinary X rays, but are calculated to both *educate* and *amuse*, and the *artistic* nature of their results has been testified to, amongst others, by several *ordinary R.A.'s*."

* * *

Inside the tent was a table bearing a small glow lamp worked by a battery to represent the Crookes' tube, together with a lot of interesting but apparently useless apparatus, so far as the performance was concerned; for, after a brief "lecture" by one of the "professors" in charge, a candidate came forward to have his hand "shadowgraphed." Laying the hand on what looked like an ordinary blotting pad, it was carefully covered with a dark cloth and a thick book, upon which, when all was declared to be ready, the two operators exerted such an amount of pressure as to extort a yell of pain from the victim, who was then quietly informed it was all over. Then from out the folds of the blotting pad was produced an admirable impression of the hand, the combined result of the heavy pressure and *a sheet of "carbonised" paper*. But the greatest success of the afternoon was the reproduction of the foot of one of the gardeners, which showed only a series of rows of hobnails. This was described as "slightly underexposed, but highly interesting, as it showed so clearly the superior transparency to these rays of the iron nails."

* * *

Messrs. Newman & Guardia of 92, Shaftesbury-avenue write: "We have pleasure in informing you that we have turned our business into a limited liability company. This, however, has been a purely private arrangement, and no shares have been offered to the public. The business will continue under our sole management, and every instrument bearing our name will, as before, be made and tested under our constant personal supervision."

SILVER CHROMATE.

Inasmuch as the silver salts play so prominent a part in photographic work, each one of them, however apparently unimportant, possesses an interest for photographers altogether independent of any practical use or application it may have. This is the case with regard to silver chromate, in connexion with which some discussion has been going on in the Inquirer column during the past week or two.

Chromate of silver, as such, has hitherto found no immediate application to any photographic purpose, although indirectly its services have been called in in more than one process, chromic acid acting as a sort of useful go-between in various reactions in which silver salts are concerned. The well-known application, for instance, of bichromate of potash in correcting a foggy emulsion depends upon the action of the loose atom of chromic acid upon the particles of silver in a state of semi or incipient reduction, which constitute the fog, by virtue of which they are brought more freely within the scope of the free haloids present, to be restored by them to the condition of normal haloids of silver.

Some years ago a method of emulsification was introduced by a French chemist, based upon the precipitation of silver chromate, which, after washing, was incorporated with the gelatine, and subsequently converted into bromide of silver by the addition of a soluble bromide. The *raison-d'être* of such a process is not very palpable when we look at the fact that such an emulsion still requires to undergo the process of washing before it is fit for use, and the only advantage that we could ever recognise as derivable from the method was that, in the days when the conditions requisite in emulsification were less thoroughly understood than they are now, this mode of working went far to ensure a product that would work clean and free from fog.

As a pigment for dark-room windows, chromate of silver has indeed been recommended, and, if properly prepared and used, no doubt fulfils the function successfully; but even here its value has been discounted, while the latest proposed application, for the purpose of making transparencies of such subjects as its pronounced colour will suit, seems to be chemically beyond attainment, at any rate in a direct manner, since those methods which are practicable for the purpose of converting the reduced photographic image into silver chromate, produce it for the most part in a soluble, or partly soluble, condition.

According to *Watts' Dictionary*, if metallic silver is acted upon by strong solution of potassium bichromate, acidified with sulphuric acid, the result is an acid chromate of silver, corresponding in composition to the potassium salt, and said to be "partly" soluble in water. Similarly, the action of such a solution upon a photographic image should produce the same result, namely, should convert the image into one of red chromate of silver, which on after washing would partially disappear. To a certain extent such is the case, though the colour of the converted image is not usually the rich red of silver chromate, or, if it is, it quickly changes, leaving a sickly, yellowish-brown deposit, having none of the characteristics of silver chromate as we know it.

The question of the existence of two separate chromates of silver, corresponding to those of potassium, has been more than once raised, and the description of the acid chromate given above does not seem to argue very strongly in favour of its being a definite compound. A substance that is "partly" soluble in water must, if of definite composition, be very easily decomposed — even, in fact, by contact with water, or else, which seems far more likely, it is a mixture of two or more substances. A definite compound may be "slowly" soluble in water, and totally soluble if sufficient time be allowed; but, if a point is reached at which it ceases to dissolve, it seems reasonable to believe that it is not a definite compound, and this is just the position in which the supposed acid salt stands.

If solution of nitrate of silver be precipitated with a solution of neutral chromate of potassium, a rich purple-red precipitate is formed, which is quickly washed free of any excess of either reagent, and then resists all further action of water. If, instead of the neutral chromate, the bichromate be employed, a precipitate is similarly formed; but it is of a much brighter colour, with more of a crimson or even scarlet tint; but the difference does not cease there. If allowed to stand until the precipitate has settled, the supernatant liquid will be of a deep red colour, even though there be no excess of bichromate, showing that the precipitate itself is partially soluble; and on pouring this off, and replacing it with fresh water for a number of times, each will extract a gradually decreasing quantity of colouring matter until, at length, a point is reached at which the supernatant liquid remains colourless. If the coloured liquids be tested, they will be found to contain silver, showing that the colour does not consist simply of excess of bichromate of potash.

From which we are led to believe that the supposed acid chromate of silver does not exist as a definite compound, or, if it does, it is decomposed by water.

Photography and the School Board.—It seems that one day last week the London School Board indulged its vanity in being photographed while in session. As the time was late in the day, and the light was bad, the members were enjoined to remain perfectly quiet while the operator counted sixty. Evidently the task set them was harder than the majority expected, because, when the "sixty" was reached, it was, it is said, hailed with loud cheers. I would be interesting to learn how many members of the Board are not altogether satisfied with their portraits as depicted.

Vesuvius Active.—According to a News Agency telegram from Rome, Vesuvius, after being dormant for a year and a half, has again awakened, and is in a state of eruption. Two streams of lava are descending the plain of Ginestre, and threatening the line of the observatory. It is added that there is no immediate danger. So far, that is satisfactory; but, as we have pointed out before, an observatory on a mountain, whether Vesuvius or any other, is not the residence that many would choose. The occupants of more than one have had narrow escapes from the elements at times.

Round the World with Cycle and Camera.—Three cyclists started one day last week from St. Pancras Church, accompanied, according to a lay contemporary, by the "inevitable camera" and the minimum of personal luggage, for a cycling trip round the world. It is added that, if all goes well, the tourists will be back again in England in a couple of years' time. A good many photographers will naturally be speculating as to the number of plates or films these travellers will carry with them on their cycles as a two years' supply, in addition to their personal luggage. If they take the whole with them on their machines, the supply, one would surmise, is very limited for a "round-the-world" tour which is to occupy a couple of years.

A Little-known Picture Gallery.—It may not be generally known to many of our readers that it is the custom with Royal Academicians, on their election to membership, to present one of their works to the Academy, usually one of those shown at the last or current Exhibition. It may be imagined that every artist wishes to present one of his best works, so the collection, though not large, contains some of the finest examples of the present and past Academicians' pictures. This collection is depesited at the Royal Academy, Burlington House, and is known as the Diploma Gallery. It is open free to the public on week days. We allude to this interesting Gallery because it does not figure in most of the usual lists of the picture galleries of London.

Raiding the North Pole.—If the Pole is not reached, it is certainly not from a lack of expeditions. There are the Nansen, Jackson-Harmsworth, Andrée (balloon), Peary, all now well on the way. In addition to these there are other arctic expeditions—Sir Martin Conway's and the Swedish Geer-Knorring, &c. In all of these photography is said to be a prominent feature; so it was to have been in most previous ones, though very little has been seen of the results. Although the attempts to reach the Pole have ended in failure, still one would have expected some photographs of the parts visited, or objects met with, to have been forthcoming. However, it is to be hoped that the expeditions now on the way will be more successful in their attempts, both in reaching the desired goal and in photography, than their predecessors. It requires a good deal of courage to face the arctic and antarctic regions, and the uncertainty of when the explorers will be able to get away from them again.

The Metric System.—There really seems some prospect of this system being adopted in this country at no very remote period. In the House of Commons, on Friday last, Sir S. Northcote put a question to the President of the Board of Trade as to whether he would, this session, introduce a Bill to deal with the metric system, so that the Chambers of Commerce, and others interested, might have sufficient time during the recess to consider the proposals of her Majesty's Government on the subject. In reply, Mr. Ritchie said he should be glad to introduce the Bill, as he knew that great interest was being taken in the matter. But he added, that of course he should not introduce it with the intention of proceeding with it this session. From this it would appear that something is likely to be done, eventually, to establish the metric system in Great Britain. Nobody would welcome the universal adoption of that system more than photographers, because all the Continental formulæ are given according to it and ever have been.

Photographs of Feet.—Photographers, just now, are eagerly on the look-out for something in the shape of a novelty to increase trade. This may (?) be of service. A paragraph has been "going the round" to the effect that the latest fashion in Sydney is to have the feet photographed. The paragraph adds, significantly, that is, if they are supposed to be Trilby ones. That we can quite understand, for we cannot imagine any one, male or female, the possessors of feet bearing a plentiful crop of corns, even with a bunion thrown in, desiring to perpetuate them by means of photography. If this kind of thing really is the fashion in Sydney, which is doubtful, it should make it good for the chiropodists as well as photographers, the same as photography often brings grist to the hairdresser's mill. Possibly the appearance of the feet can be as much improved by the chiropodist as the hair can be by the hairdresser, and the owners would certainly like them to be shown to the best advantage. Some time ago it was rumoured that, in Paris, there was a craze amongst ladies for having their hands photographed. But the Antipodes are credited with making a feature of the other extremities.

PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

LEEDS MEETING, TUESDAY, JULY 14 (*continued*).

WE append the paper on the *Fixing and Washing of Paper Prints* read by Mr. A. Haddon at the meeting of the Convention on Tuesday evening, July 14.

FIXING AND WASHING OF PAPER PRINTS.

By A. HADDON.

THE permanency of a print depends on the thorough removal of salts of silver from the high lights and the subsequent elimination of the fixing agent. The removal of the fixing agent can be easily and most rapidly effected by means of plain water, but the complete removal of the insoluble salts of silver, in the case of albumenised paper, is a task which up to the present has not been accomplished. Hyposulphite of soda will dissolve with ease the insoluble inorganic salts of silver from the paper, but the organic salt, most probably albumenate of silver, is not so easy to dissolve, and, if silver prints are to be made more permanent than they are at present, we must devote our attention to the solution of this difficult problem. The complete removal of the organic salt is not an impossibility, but we must consider the effect of the reagent on the material of which the picture itself is formed.

On August 3, 1893, Mr. Grundy and myself read a paper before the London and Provincial Photographic Association, in which we gave in detail our endeavours to arrive at the cause of the fading of prints on albumenised paper, and also the time necessary for the complete removal of the hyposulphite of soda from such paper by washing in running water.

The method we adopted was briefly this:—Albumenised paper was sensitised on a fifty grain nitrate of silver bath, neutral, for three minutes, the paper was then allowed to dry in the dark. When dry it was cut up into pieces measuring $5\frac{1}{2} \times 8\frac{1}{2}$, *i.e.*, each piece was one-eighth of a sheet. Three sheets were necessary, and each piece from the same sheet was marked so as to distinguish the pieces from the different sheets.

The paper was then washed and fixed just as would have been done had these pieces of paper been prints instead of unprinted paper. The strength of the hypo solution was twenty per cent., and the time of fixation, as usual, fifteen minutes.

In all cases a quarter of a sheet was dealt with in order to obtain a sufficient quantity of material to work upon, and, in order to obtain a mean result, the two pieces were selected from different sheets.

After the washing was completed, two pieces were set aside to determine the quantity of silver to be removed and the amount of sulphur in the paper after fixation, also two pieces were selected to estimate the silver, soluble and insoluble, and the total sulphur. The remainder of the fixed paper was then transferred to a large vessel filled with water, and into which water was running from a piece of indiarubber tubing connected to the water supply. The temperature of the water was 13° C. During the first hour the pieces of paper were constantly turned over by hand in order to prevent them sticking together.

Two pieces were removed at the end of 5, 10, 15, 25, 40, 60, 90, 120 minutes, and 19 hours, and the amounts of sulphur and silver determined.

The estimation of the sulphur and silver was carried out as follows:—

In each case the two pieces of paper were allowed to drain for five minutes, and then torn up into small pieces and placed in a large beaker with a mixture 100 c. c. of nitric acid, and 200 c. c. of hydrochloric acid (free from sulphur), covered with a clock glass, and heated on a sand bath till the paper was completely destroyed. The solution was then taken down to dryness, and 250 c. c. of pure distilled water and three drops of hydrochloric acid added, and the whole heated to boiling, allowed to cool, and filtered, and the filter paper broken and washed with boiling distilled water. The filtrate was heated to boiling point, and chloride of barium added, which precipitated all the sulphates present as barium sulphate. This was collected on a filter, washed, dried, and weighed in the usual way, and from the weight of sulphate of barium the amount of sulphur present calculated.

The chloride of silver on the original filter paper was dissolved out by means of ammonia, and precipitated with nitric acid, filtered off, and treated as in the usual manner.

The figures obtained were as follows:—

	Weight of Sulphur. Grammes.	Weight of Silver. Grammes.
In original paper	·0050	·0734
,, water adhering to paper	·000032	——
,, paper fixed but not washed	·2243	·0086
,, ,, after 5 minutes' washing	·0063	·0051
,, ,, ,, 10 ,, ,, ...	·0045	·0035
,, ,, ,, 15 ,, ,, ...	·0048	·0037
,, ,, ,, 25 ,, ,, ...	·0044	·0037
,, ,, ,, 40 ,, ,, ...	·0043	·0033
,, ,, ,, 60 ,, ,, ...	·0046	·0036
,, ,, ,, 90 ,, ,, ...	·0047	·0038
,, ,, ,, 120 ,, ,, ...	·0045	·0040
,, ,, ,, 19 hours ,, ...	·0047	·0039

From these figures it will be seen that, after ten minutes' washing in rapidly changing water, as much hypo and silver are eliminated as can be removed in nineteen hours. After ten minutes' washing, the quantities of sulphur and silver become constant.

From the figures given above, it can be easily calculated that about a quarter grain of metallic silver remains in a whole sheet of albumenised paper, and this after the paper has been as thoroughly fixed as is possible using hypo, and after washing so as to remove all that water can dissolve out.

This quantity of silver spread over an area of 17×22 in. might at first sight seem to be so small as to have no colouring power when converted into chloride and acted on by light.

Paper fixed and washed as described when brought into contact with sulphuretted hydrogen turns brown. When the gas is used it requires time, but when a solution of the gas is employed the action is much more prompt.

The existence of silver in albumenised paper which has not been exposed to light, but has been fixed and washed, can be easily shown by first converting the silver, in whatever form it may exist in the paper, into chloride (by soaking it in chlorine water and washing) and then resensitising by brushing over the surface a weak solution of nitrate of potash. Such paper, when exposed under a negative, gives a fairly strong print—much stronger, indeed, than would be ascribed to the small quantity of silver present.

In the case of gelatino-chloride of silver paper it is possible to remove the whole of the silver when the paper is fixed in a fairly strong solution of hypo, and the amount of washing, with running water and proper care, was not found to exceed that required in the case of albumenised paper.

It ought not to be astonishing that the whole of the silver from the high lights of pictures on such paper can be removed, as most probably the gelatine is never, during the preparation of the emulsion, in presence of an excess of nitrate of silver, and from this cause no organic salt of silver is formed, as in the case of albumenised paper. Gelatine, however, is a very treacherous compound to deal with, and, if any change in colour take place in a print on such paper, it must be due to imperfect fixation, bad washing, a combination of the two, or to the gelatine itself undergoing change.

Long soaking in the case of gelatine papers is a disadvantage, as the water dissolves out the alum used by the manufacturer to harden the gelatine, and, if under these circumstances the prints are squeegeed to glass or ferrotype plates, they invariably stick, and cannot by any means be removed perfect.

Many photographers are under the impression that, in consequence of the greater thickness of the layer of gelatine as compared with albumen, it requires a longer soaking to remove the salt: but this is a mistake, as gelatine allows the solution of the salts to diffuse through it with equal or even greater facility than in the case of albumen.

The results I have given you thus far are those obtained when the paper has been washed in running water; but this mode of washing cannot be universally employed, as in some cases water may be scarce, and in others it may not be convenient to leave the prints to the tender mercies of the servants in the kitchen, or even in the bath room, and then it becomes necessary to remove the hypo by soaking the prints in water contained in shallow dishes. When this method of washing is adopted, three questions have to be answered before we can say that all the soluble salts have been removed from the prints.

1. What must be the ratio of the volume of water to the area of paper to be washed?

2. How long must the prints be allowed to soak in each quantity of water?

3. How many changes of water must the prints be subjected to?

These questions we have endeavoured to answer in a paper contributed to the *Photographic Review*, June, 1896, and also read before the London and Provincial Photographic Association.

We selected albumenised paper in preference to gelatino-chloride, as the latter is usually so loaded with sulphate of barium that it is exceedingly difficult to obtain clear solutions by filtration through paper, especially when treating the ash of the burnt paper with ammonia; and, from what we now know, it is perfectly clear that what is true of the one kind of paper is equally true for the other as regards time of washing.

We did not attempt to determine the amount of sulphur left in the paper, as it will be remembered that, in the case of albumenised paper, washed in running water, the sulphur and silver disappeared at the same rate, and that, when the quantity of silver became constant, then also did the sulphur, so that the determination of the silver, left at given intervals of washing, was a difficult guide to say how many changes of water, under given conditions, the paper should receive.

The albumenised paper was marked, sensitised, washed, and fixed as already described.

The first thing to be decided before proceeding to the washing of the paper was the ratio of the volume of water to area of paper. For convenience of measurement, we settled on 1 c. c. per square centimetre of paper, *i.e.*, roughly about 1 fluid ounce of water to every 4½ square inches of surface to be washed.

After the prints had been fixed the requisite time, they were plunged and separated from each other as rapidly as possible into the measured quantity of water. After soaking for five minutes with constant movement, two pieces were taken out and dried, the remainder being transferred to another dish with the quantity of water diminished in proportion to the area of paper removed.

This operation was carried on till the last pieces received ten soakings of five minutes each in ten different changes of water.

A portion of each washing water was set aside for testing with permanganate of potash, iodide of starch, and sulphuretted hydrogen, dissolved in water.

It was found, by a preliminary experiment, that one drop of each of the solutions of permanganate and iodide of starch produced a distinct colouration in a test tube, filled with water, six inches long, when looked through lengthwise at a sheet of white paper. In order to ascertain when the hypo in the washing water had exactly done its work, such a number of drops of the reagents were added to the water, in similar test tubes, so as to just match the tints in the test tubes filled with plain water and one drop of reagent.

The number of drops required in each case, and the amount of silver left after each washing, will be given in a table presently.

The papers being dry, they were placed in a porcelain dish, and heated till ash free from carbon was left. The ash was then washed several times with boiling distilled water, and then boiled with dilute nitric acid, in order to dissolve out the metallic silver. The contents of the beaker were then filtered and washed, and the ash on the filter paper subjected to the action of strong ammonia, in order to dissolve any silver chloride that might have been formed due to impurities in the nitric acid. This, when filtered, was treated with nitric acid, and added to the previous filtrate; the whole was then heated to the boiling point, and a few drops of hydrochloric acid added to precipitate the silver as chloride. The precipitate was then collected and weighed, and the silver estimated in the ordinary way.

The following table gives the results obtained:—

Change of Water.	Silver in Quarter Plate.	Number of Drops of		Sulphuretted Hydrogen.
		Permanganate.	Iodide of Starch.	
1	·0055	more than 10	more than 10	brown colour.
2	·0045	„ „ 10	„ „ 10	faint tinge.
3	·0040	2	3	no colour.
4	·0040	1	1	„ „
5	·0044	1	1	„ „
6	·0042	1	1	„ „
7	·0044	1	1	„ „
8	·0040	1	1	„ „
9	·0043	1	1	„ „
10	·0040	1	1	„ „

These results show that, at the end of the third washing, the amount of silver becomes constant, and that farther washing has no effect as regards reducing the quantity of silver left in the paper.

The hypo indicators also point to the same result, that, after the third change of water, no hypo is present to discharge the colour of the permanganate or decompose the iodide of starch.

Three soakings in different water seems at first sight insufficient washing to remove the salts, but at the same time we must remember that all that the water has to do is to displace a given volume of the solution of hypo contained in a medium through which diffusion can take place very readily. The silver is already in solution, and it is merely a matter of rate of diffusion. Naturally it takes longer for the last traces to be removed than it does for the bulk of the salts to pass out.

Five minutes ought to be amply sufficient for the salts to diffuse out into the surrounding water; and, if this be so, it becomes a very simple calculation to find how many changes of water the prints must be subjected to in order to reduce the quantity of hypo in a given area of paper to something so very small that is is incapable of producing any deleterious effect on the print.

Hypo eliminators have been recommended at different times, and praised by some and abused by others. If the same amount of trouble be taken, using plain water instead of these salts, I am sure equally good, if not better, results will follow. Any hypo oxidiser is dangerous, in that it is likely, by destroying the solvents, to throw down some silver compound when it would not have been deposited if water only had been used. Fortunately, however, we are generally recommended to give the prints three or four washings before applying the compound, and this is the safeguard, for, if it had been applied at an early stage of the washing, its effect for evil would be very much more marked than has been the case.

The removal of hypo and the silver compounds formed is an easy matter if done with care. I do not mean to say that the mere soaking of paper at the bottom of a dish for fifteen or twenty minutes will remove these salts; the prints must be constantly turned over so as to bring fresh water into contact with them. The two or three hours washing, as still recommended by several paper-makers, is a mistake, especially if the prints are left to take care of themselves. In the case of gelatino-chloride papers even proper washing for that length of time is detrimental to the quality of the gelatine, it tends to remove the alum the maker has purposely added in order to harden it, and if it be removed by long soaking, on attempting to glaze such prints by attaching them to any support, they invariably stick. Give a short washing and the result is different.

I am certain, if photographers will persist in their old-fashioned way of washing prints for six or eight hours, that it would amply repay the water companies, where much printing is done, to supply labour free, to constantly change the prints in the water, and give short washings, thus ensuring better results and a less waste of that most valuable natural product H_2O.

The discussion on Mr. Haddon's paper will be found on p. 456 of last week's JOURNAL.

WEDNESDAY, JULY 15 (*continued*).—THE ANNUAL GENERAL MEETING.

The Annual General Meeting of the members was held in the Philosophical Hall on Wednesday morning, the President (Mr. H. P. Robinson) occupying the chair.

Mr. R. P. Drage (Hon. Secretary) read the annual report, showing that up to date the Convention numbered 295 subscribers, of whom 198 had signed the attendance book. There was a favourable balance on the year of 77*l.* 9*s.*; a further sum of 50*l.* had been invested in the Post Office Savings Bank, and the total Convention fund up to December 23 of last year amounted to 127*l.* 9*s.* A recommendation was brought forward by the Council to the effect that there should be some memento of the great services rendered to the Convention by the late Mr. Traill Taylor, and it was suggested that a sum of twenty guineas be devoted to the Traill Taylor Memorial Fund. Mr. F. P. Cembrano moved, and Mr. A. L. Henderson seconded, that a sum of twenty guineas be set aside for the purpose: and this was agreed to, it being left to the administrators of the fund to decide the particular object to which the money shall be applied.

The Secretary stated that an invitation had been received from the Great Yarmouth Camera Club to hold the Convention meeting of 1897 at Great Yarmouth.

Dr. Adcock (Great Yarmouth) said that Yarmouth would be very pleased to have the Convention there next year, and he was sure that the Mayor and Corporation would accord their co-operation.

Mr. George Mason said that the whole of the Glasgow societies joined in inviting the Convention to meet next year at Glasgow.

Mr. John Stuart supported Mr. Mason, but said that he was conscious that Yarmouth really had the preference. However, he looked forward to the Convention meeting at Glasgow in 1898.

Mr. F. A. Bridge formally proposed that the invitation of the Great Yarmouth Camera Club be accepted, and this, being seconded by Mr. J. Porritt, was carried unanimously.

A hearty vote of thanks was passed to the local Committee for their labours on behalf of the Convention, and the compliment was acknowledged by Mr. J. H. Walker, Mr. Herbert Denison, and Mr. Godfrey Bingley, each of whom was warmly applauded by the meeting.

The General Committee having been elected, certain alterations in the rules were made on the proposition of Mr. C. H. Bothamley. Briefly, the new rules provide for the abolition of delegates, and of the General Committee; the election of the Council by the members instead of by the General Committee as hitherto, and the adoption of voting by ballot. The details of the alterations were referred to the Council for arrangements.

Mr. Frank Bishop made a few remarks on the aims and objects of the Photographic Copyright Union, to which he invited the support of photographers.

Mr. Addyman suggested that the Convention might take in hand the subject of a fixed tariff for headquarters, similar to that adopted by the Cyclists' Touring Club, and the President promised that the Council would take the matter into consideration.

The election of the Council was then proceeded with, and resulted as follows: Mr. H. P. Robinson, Mr. A. Haddon, Sir Howard Grubb, Mr. E. J. Appleby, Mr. Thomas Bedding, Mr. Godfrey Bingley, Mr. C. H. Bothamley, Mr. F. A. Bridge, Mr. F. P. Cembrano, Mr. Alexander Cowan, Mr. Herbert Denison, Mr. M. J. Harding, Mr. H. M. Hastings, Mr. Paul Lange, Mr. C. Phipps Lucas, Mr. Percy Lund, Mr. J. L. Lyell, Major Lysaght, Mr. George Mason, Mr. Thomas Mayne, Mr. W. W. Naunton, Mr. J. Porritt, Mr. A. Pringle, Mr. J. C. Ruthven, Mr. A. Seaman, Mr. J. Stuart, Mr. H. Sturmey, Mr. W. Taylor, Mr. A. Tate, Mr. E. J. Wall, Mr. H. Snowden-Ward, Mr. G. Watmough Webster, Mr. S. B. Webber, Mr. J. B. B. Wellington, Mr. F. W. Williams, Mr. A. F. Mowll, Mr. A. Horsley Hinton, and Mr. W. D. Welford.

The proceedings of the General Meeting then terminated, and members adjourned to the Yorkshire College. They were introduced to Professor Bodington (Principal of the College), who gave them a cordial welcome, and they were then conducted over the various departments by Professor Smithells. Mr. Donald MacIver then took the group on a stand specially erected for the purpose. In the afternoon the members divided into scattered parties, and visited places of interest within easy distance of the city, Kirkstall Abbey and Roundhay Park being the chief points of attraction. The weather was dull and rather cold for the time of the year, and not much work was done with the camera. Some of the members also paid a visit to the Carlton Hill Works of Messrs. Watkinson & Co., manufacturers of photographic apparatus.

The Annual Dinner.

The annual dinner took place at the Queen's Hotel. Covers were laid for over 120 ladies and gentlemen. The President (Mr. H. P. Robinson) occupied the chair. Among the guests present were Principal Bodington, Mr. J. W. Willans, Mr. Edmund Wilson, and Alderman Hepworth. The Chairman gave the toast of "The Convention," which, he said, at no period had been in a better financial or social position. A great deal of their success was due to their Secretaries, Mr. Drage and Mr. Bingley, whose names he coupled with the toast.

Mr. Drage, in responding, declared that the Leeds Convention, in the numbers attending it, and in other respects, had been the most satisfactory they had held. He was not born an orator, so that they would have to excuse him as much as possible. A great deal of work was attached to the organization of the Convention, but he had been ably assisted by Mr. Bingley. The work was amply recompensed by the smiling faces round him, and they were much indebted to the photographic press for the assistance given.

Mr. Godfrey Bingley, the Local Secretary, also replied. If he had been born an orator, he would have found some difficulty in expressing what he felt.

Mr. C. H. Bothamley gave "The Local Committee," coupled with the names of Mr. H. Denison (Hon. Treasurer) and Dr. Thomas Thresh. The Leeds Committee had, he said, engineered things uncommonly well. They had even managed to break the record by providing them with fine weather on the Convention Tuesday, which was always a wet day with them. They had been received in the city with open hands, and were going away with a great deal more than they brought. Knowing, as he did, the district fairly well, he could appreciate the difficulty the Committee had in arranging their programme.

Mr. Denison and Dr. Thresh briefly replied.

Mr. A. Haddon (ex-President) proposed "Other Photographic Societies."

Mr. Peter Gilston, J.P. (ex-Mayor), replying as the President of the Leeds Photographic Society, made a humorous speech, in the course of which he made some references to the New and Old Photography. He said he had in his way taken some interest in photography, not only as a hobby, but as a study, and he had derived a good deal of pleasure from it. He might not as yet have done anything remarkably great, but he was not without hopes. It was well we should have hobbies, and he knew of none better than photography, which, like mercy, was twice blessed—it blessed in the gathering and in the distribution.

Mr. Green Hirst, the President of the Leeds Camera Club, also replied. The Club, he stated, was started about two years ago with twenty-eight members, but it had now nearly 200.

Mr. F. P. Cembrano proposed "The President," and with the acknowledgment of the compliment by Mr. Robinson the speech-making came to an end. The remainder of the evening was devoted to songs and other musical items.

Thursday, July 16.—Excursion to York.

Over a hundred members undertook the excursion to York, led by Mr. J. H. Walker, Mr. Godfrey Bingley, and Mr. Herbert Denison. On arriving in York, they repaired direct to the grounds of the Yorkshire Philosophical Society, where they were welcomed by Dr. Tempest Anderson, Mr. J. Saville, Mr. H. M. Platnauer, Mr. G. C. Dennis, Mr. F. B. Cattley, Mr. Watson Hirst, and other gentlemen. The Conventioners soon dispersed about the beautiful old city, and we subsequently gathered that, dividing themselves into five or six parties, each having a guide who knew what objects would be best calculated to catch the eye and fancy of the photographer, they set out in quest of some of the tit-bits of quaint and historically or archæologically interesting architecture with which the city abounds. A given route was started at different stages, hence each group of workers saw much of what was worthy of their artistic effort without clashing with other sections. One party that had Mr. Cattley for its cicerone commenced operations in the Shambles and High Petergate, where the old buildings are replete with interest. Thence they went to Monk Bar, which Mr. Britton regards as the most perfect specimen of this sort of architecture in the kingdom. Next St. William's College, near the east end of the Minster, came under notice, and from there they proceeded to the Cathedral, of the exterior of which they took views from the south, the east, and the north. The west front was left till the afternoon, in the hope that the sun might assist the camera in doing greater justice to this magnificent example of Gothic architecture. Special leave was granted to photograph the south transept, the choir, the Lady Chapel, and the chapter house, inside the Minster, and advantage of this privilege was taken by a majority of the parties. From the Minster, Mr. Cattley took his representatives of the Convention to the picturesque overhanging houses in Low Petergate, and on to Bootham Bar, the Manor House, and St. Mary's Abbey. After luncheon attention was devoted to the Bar Walls, the Guildhall, and the Mansion House and its interesting contents, and Micklegate Bar, the most imposing of all the bars of the city. Drake and Lord Burlington attribute the structure to the Romans, but most writers now agree that it is Norman work. The heads of traitors were formerly exposed there. Hence, the route lay by way of Skeldergate Bridge,

the Blue Bridge, and the New Walk, snap-shots of which were taken in passing, to Walmgate Bar, the only one that retains its barbican, and which is supposed to have been the point where the Watling-street of the Romans entered. The ancient and quaint churches of St. Lawrence, St. Dennis (where the Earl of Northumberland, who fell at Taunton, is supposed to be buried), and St. Margaret's, with its fine Norman arch, having yielded some excellent opportunities, the photographers returned to the Minster. Thanks to better light and less wind, many very satisfactory exposures on the west front of the Minster were got before the various divisions of the party returned to the station." Altogether the number of plates exposed was believed to be nearly 1000.

At the evening meeting the following paper, illustrated by lantern slides, was read:—

SOME NOTES ON ORTHOCHROMATIC PHOTOGRAPHY.

By C. H. Bothamley, F.I.C., F.C.S.

It always seems to me to be a useful function of annual gatherings of this kind to take stock, as it were, of the present position of our knowledge of particular branches of photography for the purpose of seeing exactly where we stand, and what progress, if any, has been made. In the case of orthochromatic photography it must be admitted that very little progress has been made in the past few years, so far, at any rate, as methods are concerned. Erythrosine and cyanine still remain the best-known sensitisers, each in its own way, and no improvements in the modes of applying them have been placed on record. Nevertheless, these sensitisers are of such great practical value that orthochromatic or isochromatic plates have come largely into use, and may fairly be said to be now regarded as indispensable in several special classes of work. On the other hand, it is not likely to be disputed that orthochromatic plates have not with anything like the same completeness displaced ordinary plates for landscapes and other outdoor work. The explanation seems to lie in the fact that most outdoor work is done during the middle of the year, when all subjects, whatever their colour, reflect a very considerable proportion of white light, and the ordinary plates are thus put more nearly on the same footing as orthochromatic plates than they are in the early spring or late autumn.

It is satisfactory to be able to state that, so far as my own experience is concerned, commercial orthochromatic or isochromatic plates are now very much better in both general and special qualities than they were some seven or eight years ago. There are at present available to photographers who do not wish to orthochromatise their own plates, or who wish for such plates with better keeping qualities than can be obtained by the bath process, no fewer than three different brands of commercial plates showing great sensitiveness to yellowish-green and greenish-yellow rays, one brand which shows considerable sensitiveness to yellow-orange and orange-red rays, and one brand which is sensitive to a very useful extent to all rays from yellowish-green to orange red. At the same time, all these plates show, of course, the strong sensitiveness to blue and violet rays which is characteristic of gelatino-bromide plates.

In order that we may be able to search systematically, and not hap-hazard, for new sensitisers, it is indispensable that we should ascertain exactly how the dyes used act as sensitisers, and what is the relation between their sensitising action and their composition and general properties. There are two well-known hypotheses as to the mode of action. According to Eder and Vogel, the sensitiser absorbs the energy of the light rays, and its molecules are thereby thrown into violent agitation. This motion is communicated to the molecules of silver bromide in contact with the molecules of the sensitiser, and they are consequently thrown into such violent agitation that they split up and yield a latent or developable image. According to Abney, the dye used as a sensitiser is first oxidised, and the oxidation product and the developer together reduce the silver bromide and so produce an image.

Experiments that I have made show that with all the ordinary sensitisers, whether added to the emulsion or applied in a bath, the orthochromatic effect is produced, or, in other words, the less refrangible rays act on the plates, even when the plates are exposed whilst immersed in strongly reducing solutions, such as a solution of sodium sulphite containing pyrogallol and a small quantity of alkali. It is inconceivable that any intermediate oxidation of the dye should take place under these conditions, and it follows that Abney's hypothesis is not tenable. On the other hand, the alternative hypothesis is only an hypothesis, and the precise mechanism of the action of the sensitiser is still unknown to us.

Another point of interest is the question of the relation between the maximum absorption of the sensitising dyes and the position in the spectrum of the maximum action of the less refrangible rays. A series of long and careful experiments some time ago led Eder to the conclusions: firstly, that the maximum *absorption* of the dye in a simple gelatine film does not coincide with maximum absorption of dyed silver bromide; and, secondly, that, although the position of maximum photographic effect of the less refrangible rays is not coincident with the maximum absorption of dyed plain gelatine, it is coincident with the maximum absorption of *dyed silver bromide*. On the other hand, some later experiments by Dr. J. J. Acworth lead him to the conclusion that this coincidence is non-existent, and that the position of maximum photographic effect is somewhat nearer the red end of the spectrum than the maximum absorption, this result being in accordance with a theory of Wiedemann's.

Last year, in a communication to the Chemical Section of the British Association, I pointed out that, although Acworth's experiments lead to a number of interesting observations, they are, so far as their main conclusion is concerned, vitiated by a fundamental error. The method adopted was to add a definite quantity of dye to a definite quantity of emulsion of known composition. In most, if not all, cases, however, the quantity of dye added was much larger than could enter into intimate association with the silver bromide, and consequently there was an excess of dye, which was simply staining the gelatine. The absorption measured was, as a matter of fact (and this is readily seen on examination of Acworth's own tables), the absorption of *dyed gelatine*, and not of *dyed silver bromide*. Somewhat later Von Hubl made an exactly similar criticism. It follows that the accuracy of Eder's conclusions is, in reality, not disturbed by Acworth's results. It is, however, very doubtful whether the point can be quite definitely settled by experiment; at any rate, with our present means of observation, since the quantity of dye necessary to produce the maximum sensitising effect is so extremely small. A properly washed orthochromatic emulsion differs very little in colour from an ordinary emulsion. The point is one of considerable scientific interest, but at present it has no very direct bearing on immediate practical needs, and it is the chemical side of the problem that at present has the greater importance from the point of view of the discovery of new sensitisers.

A vote of thanks having been passed to Mr. Bothamley for his paper, Mr. F. W. Branson, of Leeds, who had a large collection of radiographic apparatus on view, gave a short discourse on Radiography. First, by means of a fluorescent screen, he showed a bullet in the hand of a youth who accidentally shot himself three weeks ago. The ball entered the centre of the palm, and was imbedded in the base of one of the fingers. Mr. Branson said that Edison had cabled, with reference to calcium tungstate, that the salt must be crystallised. He, on the contrary, preferred the material in an amorphous condition, and, when this was used as a substratum for a sensitive film, a radiograph might be taken in a twentieth of the usual time. For example, the bones of the human hand might be taken in a single second. Another new method of procedure described was one whereby a negative and several impressions on paper might be taken at the same time, merely by passing the X rays through a box containing at the base an ordinary photographic plate, and above it as many pieces of matt-surface bromide paper, according to the number of impressions required, the object to be radiographed being placed outside the box, so that the X rays might first pass through this, then through the papers, and finally through the surface of the negative. Thus, added Mr. Branson, all were developed together, all being equally exposed.

Mr. Branson illustrated his remarks with numerous experiments, high vacua tubes, fluorescent screens, &c.

Mr. A. Haddon, in the course of a few remarks, adverted to the desirability of varying the degree of vacuum of tubes on account of the varying opacity of bodies to the X rays. As to the suggestion of Mr. Branson, that the tungstate of calcium, prepared by double decomposition and heated, was in an amorphous state, Mr. Haddon pointed out that precipitated tungstate of calcium gave no effect of fluorescence, but when raised to a red heat became fluorescent. But it was not then amorphous.

A vote of thanks having been passed to Mr. Branson, slides illustrative of Ripon and Fountains Abbey were shown.

Friday, July 17.—Excursion to Fountains Abbey.

The most beautiful weather of the week was experienced on

Friday, and, in consequence, a large party set out very early in the morning for Ripon and Fountains Abbey.

The leaders were Mr. F. W. Bedford, Mr. Denison, and Mr. Bingley, Mr. C. Watson, of Ripon, being appointed as local guide. Conveyances from the Unicorn Hotel were in waiting at Ripon Railway Station, many of the party electing to drive direct to Studley and Fountains Abbey, where they were met by Mr. T. S. Mason (Lord Ripon's agent). "Meanwhile the smaller section of the party, with Mr. Watson, first visited the Cathedral, where, through the kindness of the Dean, opportunity was afforded of inspecting the architectural details as well as to take photographs of the edifice, both of the exterior and interior, from numerous points of advantage. They then went forward to Fountains Abbey, the adjacent picturesque grounds and the romantic valley of the Skell affording ample scope for camera work, full advantage being taken of all the facilities placed at the disposal of the visitors by Mr. Mason. In addition to the ruins of the fine Cistercian Monastery, a striking contrast was afforded in a visit to the splendidly decorated memorial church of St. Mary the Virgin in Studley Park, permission to take photographs from the interior being kindly given. The old mansion of Fountains Hall (Mr. Mason's residence) was almost viewed with interest."

Over 1230 exposures (chiefly on Fountains Abbey) were made, and it is safe to say that the day will not readily be forgotten—the delightful weather, the grandeur of the old ruin, and the beautiful scenery of the district creating a deep impression on the Conventioners.

At the eveniug meeting the following paper was read:—

PHOTOGRAPHY AT THE SEASIDE.

By Frank Meadow Sutcliffe.

When I was asked to tell you something about photography at the seaside, it seemed to me that nothing could be easier; but, when I began to arrange my scattered thoughts, I found that I knew very little about seaside photography, except what I had done myself, and, as I, like every one else, have a most decided objection to be continually repeating the first person singular, I was for giving up the attempt, and for telling Mr. Pringle that the thing could not be done, when a friend, whom I will call Peter, came to my aid; so, instead of telling you about my own experiences, I will tell you of Peter's; it will relieve me considerably, and it will not hurt Peter. If you think that Peter tells you too much about one particular place at the seaside, please put it down to his ignorance of other places, and not to Peter's prejudice. He says he is quite willing to believe that the sea washes the doorsteps of other towns than the one he lives in; but, unfortunately the anchor which fastens him to that particular bit of coast is too securely fastened in the sand, or, to be more accurate, in the mud, for him ever to hope to weigh it, and taste the delights of other climes, and acquire experience elsewhere.

Inland, the year is supposed to begin on the first of January, but at the seaside it begins with the season, which varies according to the situation of the town. At Whitby, for instance, the first of January is somewhere between the middle of June and the middle of July. By the end of the latter month every house is taken, not by photographers, but by an army of young and old, carrying spades and pails—to be sure, there are many photographers among them. If you look into some of the pails, you will find a Kodak inside.

One morning last August, Peter heard that a big ship was coming in. Nowadays a ship is a curiosity at Whitby—once the fifth port in the Kingdom. With the exception of a timber ship——that is a ship laden with timber—or two, and one laden with ice from Norway, ships pass us by on the other side of the Bell Buoy. Fetching ice to Whitby seems to be a piece of foolish extravagance, for geologists tell us that three glaciers met at Whitby in the olden times. Peter says he quite believes the geologists, and that he does not think the glaciers ever parted, and that, if the top soil was scraped off, the three old glaciers would be found there to-day. He proves his belief by the coldness of his feet.

Well, as I said, Peter heard that a big ship load of ice was coming in for the fish-packers, so he went along the pier with his camera in hope of getting a picture before the sails were taken in. There were three little visitor boys sitting on the pier rails, and, as he passed, they said, "*There's another!*" On hearing this, Peter turned back. He says he does not mind being compared to a ha'porth of soap after a day's washing, but he will not be called "another." When he was a boy at school, when one boy called another "another," there had to be a fight to prove that they were not another, but themselves.

Sometimes, after Peter has been out photographing, he often thinks he *is* "another," and not himself. You should know our harbour is rather muddy in places, and sometimes he is apt to forget all about the mud in his pursuit of pictures. Only when he goes home to breakfast, and finds the front door fast, and some one at the window, saying, "You will, perhaps, kindly go round to the back, and get some of the mud off your boots and clothes before you come in," and it dawns upon him that he is very unlike the man who went out of the front door an hour before.

Then, too, the salt water sometimes takes all the starch out of his linen. Maybe, the wind has been blowing pretty strong from the nor'-nor'-east for some days, and the sea has got up, and he fills his slides, and goes on to the pier in the hope of getting some breaking waves; but, unless he is very lucky, they will get him first. You see, he can never tell whether they will break out at sea, where the camera is pointed to, or come further in and break at the pier edge under his feet. If they do, it means no more photography that day, for one good splash will wet lens and shutter through and through, to say nothing of Peter's self. Maybe, his hat is taken away, and he feels decidedly like "another" as he goes home and tries to get the water out of his lens and camera. I—no, Peter—once heard of a man who was taken off his feet at the pier end, and who struck out, so great was the quantity of sea which came over.

Cameras are as common at the seaside as bicycles are inland. What becomes of all the plates exposed by the sea is a mystery as unfathomable as the sea itself. The number of cameras is only exceeded by the number of grains of sand on the shore, yet we may hunt many a photographic exhibition round and round in vain for any prints from all the plates exposed. Perhaps the workers do not take into account the extraordinary degree of light and the luminosity of the subjects near the sea. When it is possible to take drop-shutter pictures after sunset, one cannot help thinking that many plates must be wofully over-exposed. Peter says he saw a man one bright morning last summer with a camera take out his watch and slowly count one, two, three, four, five, six, seven seconds before he capped his lens on a subject which can any day be got with a quick-shutter exposure. He felt inclined to advise him to expose another plate, and give it the twentieth of a second, but he did not like to address a stranger, especially a stranger with such a beautiful set of apparatus.

Strange photographers are seldom as shy as Peter is; perhaps they are Conventioners, who, I understand, soon get the bloom of modesty and bashfulness rubbed off—as I have never been to a Convention, I cannot say. Well, Peter was going over Whitby Bridge one morning with his camera—the bridge, you must know, divides the old and beautiful from the new and ugly town—when he was accosted by a stranger with a camera, who told him that it was no use his going over there to the old town, there was nothing worth taking. Peter pretended to be much obliged for the information. The stranger further vouchsafed the information that he was waiting on the bridge for a boat load of naked boys, but could not make out why they were so long. Peter asked him what he wanted the naked boys for, and was told that they were to be turned into water rats, but Peter did not see how a boy could be turned into a water rat, so he went away ashamed of his ignorance. He heard afterwards that by some mistake the boat load of naked boys waited a full hour near another bridge for a photographer who never came.

Some people think it always ought to be bright, and clear, and sunny at the seaside, and, if all these conditions do not exist, that it is of no use unpacking the camera. Now, to Peter's mind, the great charm of the seaside is that the weather is always changing, and that there is always a certain degree of uncertainty as to what it is going to do next. You never find fishermen afflicted with that curse which is ruining our nation, the curse of gambling; the speculating on the wind and the weather is quite enough to keep interest alive. The whole town may be enveloped in a mist one minute, when suddenly a wind springs up, and all is changed. Besides, some of the most beautiful effects are only seen in bad weather; so, if you come to the seaside in bad weather, do not go to the railway people and ask for your money back because you cannot see the sea for fog. To be sure, it requires some little courage to set up your camera in a fog, for people who still think that bright sunshine and photography cannot exist apart look on any one who puts his head under a focussing cloth on a misty day as a kind of lunatic, or, at any rate, as one who does not know much about his own business. There was one man, he is dead now—I hope Peter's erratic way of trying to take photographs in all kinds of weather did not hasten his death—

SANDELL EXHIBITION, 1897.

The Sandell Works, 213, 215, Selhurst Rd., S. Norwood.

THIS EXHIBITION of the work of our Managing Director on the Sandell Plates will be opened on APRIL 1st, 1897, and continue open until MAY 31st at the Works. It will consist of upwards of Four Hundred Pictures, principally 15 × 12, comprising: CONTINENTAL VIEWS—THE HALLS OF THE CITY GUILDS—THE GUILD HALL AND MANSION HOUSE—GRAY'S INN—LINCOLN'S INN—LAMBETH PALACE—WESTMINSTER ABBEY—WINDSOR CASTLE—PHARMACEUTICAL SOCIETY'S ESTABLISHMENT—1896 CONVENTION VIEWS. Many users of the Plates have promised contributions, and we shall welcome the support of all interested in furthering the advance of Photography. We are prepared to pay the carriage to and fro of all exhibits. Demonstrations of Practice with the Plates will be given on fixed days.

TICKETS FREE ON APPLICATION DIRECT OR THROUGH ALL LEADING DEALERS.

The SANDELL WORKS COMPY., Ltd.

Printers, Allen & Carruthers, Cirencester.

who used to annoy him very much. He always wanted to know what Peter saw *there* which he thought worth taking, and was for ever telling him that there was too much haze, or that the light was too dull, or the sunlight too fitful, and he was always inviting Peter to go to his house to see some large photographs of Venice, which were wonderfully clear, which had only cost him tenpence a piece. He wanted to know why Peter could not take photographs like them, and why he seemed to care so little whether the distance was clear or not. Hundreds of people have the same notions about photography as this man had—if they do not express it in words, they do by their faces; so, if when you are at the seaside, and you wish to be considered a clever photographer by the populace, you will see that the sun is shining and the haze has gone before you venture out with the camera, but, if you wish for pictures to please yourself and three or four of your friends, you will take no notice of the weather, nor the wise people, but will stroll round, seeking for your prey in fine weather and in foul.

For more reasons than one it is not advisable to keep the head under the focussing cloth too long, especially if working on the beach with houses above, or an avalanche of empty mussel-shells, or something worse, may be shot from above on the top of the photographer and his camera, to the delight of all the small boys round about. Peter once knew a man who swam across the river at Kirkstall Abbey, whose landlady refused to let him in when he went home. Your landlady will have equal grounds for refusing you admission if you don't keep an eye open to see that none of the refuse, which you feed pigs on in towns, but which we throw into the sea to feed the fishes, is thrown over you and your focussing cloth. There are other dangers besides pigment to be met with at the seaside. There is the tide, which has a way of its own sometimes overlooked by strangers. Peter says he has had people come to his studio with sorrowful tales of the sea—how they have unpacked their cameras on a stone, quite out of the way of the water, but, on going for another slide soon after, have found everything quite wet. He has also heard of lenses being left on a rock, being covered by the tide, and never heard of again. There was an advertisement in our local weekly newspaper one summer which ran as follows:—"Lost, on the Scaur, part of the inside of a camera; so much reward," &c., but it did not state what part of the inside of the camera it was which was left behind. You might leave the *whole* of the inside of a camera on the moors or in the woods, and find it where you left it a month after, but a single night's tide will take not only the inside, but the outside too, of the heaviest camera clean away by next morning.

My friend Peter tells me that he often feels inclined, when he gets away from home into places where cameras are sold, to go into a shop and ask the shopman to be good enough to show him a seaside camera and legs, but he says he never has, for he knows it would be of no use. His ideal camera for the seaside is an ugly thing—it has no bellows, and is only a square box; it has no focussing rack, for when the wind is strong, it will rack in a camera with a rack as easily as winking; it has a rising front fastened with a screw, and it has not only a rising front but a falling front. Why camera-makers don't make the front to fall as well as to rise is odd. The ideal camera of my friend has the shutter near the plate, or, at any rate, behind the lens, for when the winds blows it plays the mischief with the speed of shutters, and sometimes makes them go very slowly when set to go very fast. And the legs are as heavy—no, much heavier—than the camera, without any joints or anything to stick when wet. A tripod for seaside work ought, says Peter, to be of the old-fashioned sort, without any machinery to go wrong and get out of order if sand gets into its joints. When working in wet sand, it is necessary to expose as quickly as possible after focussing, or the legs may settle down in the sand unequally.

Seaside photographers are often asked why they do not get more pictures of storms. Now, a photograph of a storm is one thing, and a painting of a storm is another. In the first place, the sky is seldom as black as painters make it, and the waves seldom as big—for, when the wind is blowing its hardest, it seems to flatten the sea down and keep it from knocking about. Then, those picturesque groupings of fisher-people are, I may safely say, never seen in real life. What you *do* see is a black mass of humanity sheltering as much as possible out of the wind. The force of the wind is seldom taken into account. You see people in paintings standing in places where nothing less than an elephant *could* stand! In fact, sometimes the only way of getting along is to go on your hands and knees. I have seen a man too proud to adopt this undignified method of progression twirled round and round, and thrown down on his face insensible. In a gale of wind one man can do nothing with a camera; even in a sheltered corner one man is wanted to hold on to the legs while the other looks after the plate and exposing. But worse than the force of the wind is its keenness. On our coast we only get rough seas when the wind is north-easterly. Standing beside the camera when a piercing wind is blowing is often more than a joke. I have felt the wind go through my coat, and cut my arm like a knife. Sometimes, after waiting, maybe, for a gleam of light for half an hour, the photographer finds his hands so benumbed that he has lost the power of using them, and, do what he will, he cannot even take hold of his camera legs to take it away, much less take his camera down and pack it up. One feels very stupid to have to ask a passer-by to be good enough to take up the camera, and carry it along till the blood, like melted lead, begins to flow again.

Not the least picturesque part of the seaside are the inhabitants thereof, especially the fishermen. Their distinctive dress of sou'-wester, guernsey, and sea boots would be worth taking alone; but, when you have besides a handsome, open, bronzed face, absolutely without guile or deceit of any kind, the photographer, and not the model, will be at fault if the photograph turns out a failure.

If not so bronzed as the men, the women are certainly more brazen-faced, and will sometimes demand half-a-crown from a strange photographer before they will stand to be taken. What with skeining mussels, baiting lines, mending nets, and feeding men and bairns, the women have little time to give a photographer, and he would be a mean fellow, indeed, who would run away with a good-looking woman's face in his camera and not want to pay for it. The amount of hard work these fishermen's wives and daughters undertake is marvellous. Let the photographer follow them when out flither-picking on the rocks, he will soon be wet through up to the waist; and then, when they have got their baskets and sacks full, let him climb with his apparatus—but a feather weight compared to the weight of their loads of flithers—with them up a cliff side, some 500 feet high, he will then think that the woman's work by daylight is even harder than the fisherman's toil and danger at sea by night.

I spoke a short time ago about photographers leaving their apparatus on the seashore. Peter reminds me of an adventure a friend of his had with a strange hand camera—a thing I know very little about. Though any one can photograph in the ordinary way with a decent-sized lens and camera, genius is necessary to manipulate a hand camera. I do not speak in jest, for I have been trying for some two years now to get a decent plate with a hand camera; so far I have got nothing which is not flat, thin, and foggy. There was a sale by auction at Whitby last year, and among the things on the table in the auction-room was a hand camera. Peter's friend, who had been looking round, took it up and examined it carefully. He was rather surprised to find it there among a lot of old odds and ends, for it was in perfect condition—the lens and shutter were of the most improved make—in fact, Peter's friend made up his mind to come to the sale, and had visions of seeing that camera knocked down to him for five or six shillings. The only part about it he could not understand was the changing arrangement, so he took the back off and emptied the plates, which were inside, out while he made himself master of the mechanism. This accomplished, he had just put the plates back in their place, and was putting the camera down on the table, when a stranger came up, who said abruptly, "What are you doing with that?" "Just been having a look at it" Then the stranger turned very red, and began to splutter, "How dare you touch what does not belong to you?" The photographer replied calmly that he expected everything which was in the sale-room could be examined, and that was why they were on view. Then the man turned redder than before, and said, "You did not open it, did you?" "Of course I did," came the answer. Then, when the stranger walked off, muttering and cursing, with the camera under his arm, it dawned upon Peter's friend that the camera was *not* for sale, and that by examining the changing appliance he had exposed to light the whole of some one's day's work. Peter says his friend rushed after the stranger and offered to buy new plates, and said how sorry he was, but the man with the hand camera refused to be comforted, and went down the stairs using language which Peter cautioned me not to repeat, except on board ship or in a windy corner.

After all, photography at the seaside is like photography everywhere else—if we get more than our share of stormy weather, so that our trees give up as hopeless the attempt of trying to grow before they are many years old, those very same winds bring compensation in the shape of fresh air, which enables the photographer to work eighteen hours out of the twenty-four without feeling as weary as he would with the regulation eight hours inland.

If Leeds was only at the seaside, one thing is quite certain—she would be troubled with smoke no longer, the sea breezes would blow it all away, if they did not blow all the chimneys down; but,

then, Leeds would not be Leeds without its smoke, and Yorkshire without Leeds would be nowhere, and England without Yorkshire would be nowhere, and the world without England might just as well give up the trouble of turning on its axis, so it is just as well that Leeds is not at the seaside, after all.

I am afraid the impressions I have given you of photography at the seaside have been very indistinct, very much out of focus. May I, in conclusion, suggest that you should all go to the seaside, and get your *own* impressions? After such a hard week's work as you must have had this week, I am sure a change of air and a little rest and quiet would just set you up, or, as we say at Whitby, would just "trim" you.

In reply to Mr. Addyman, Mr. Sutcliffe said the light at the seaside was much more actinic than inland on account of the absence of smoke. The exposures were reduced to about one-fourth of those given inland.

A vote of thanks having been passed to Mr. Sutcliffe, a series of slides illustrative of beautiful places in Yorkshire, not placed on the week's programme, was next shown.

THE COUNCIL MEETING.

A Council Meeting followed. Mr. F. P. Cembrano was proposed as President for the year 1897–8 by Mr. C. P. Lucas. Mr. George Mason seconded, Mr. Sturmey supported, the nomination, and, on a vote being taken, Mr. Cembrano was declared unanimously elected.

A vote of thanks was also passed to the local Committee and duly acknowledged.

Mr. Drage intimated that he would be unable to continue the secretaryship, but was induced to adhere to the office *pro tem.* Several members of Council thought that by the engagement of a paid assistant the duties of the Secretary would be so lightened that he would be willing to retain his position.

Subsequently the principal members of the Convention met at a smoking concert, organized by the officers and committee of the Leeds Camera Club, in the Green Dragon Hotel. The Chairman was Mr. J. Green Hirst (President), and the Vice-Chairman, Mr. W. A. M. Brown (Vice-president). To the latter gentleman the company, which numbered several hundreds, were indebted for the evening's hospitality, for which he was cordially thanked by those present. Songs, recitations, and instrumental solos constituted the larger portion of the programme, and there were also several appropriate toasts. A number of professional *artistes* from the Princess's Palace appeared. The pianist was Mr. W. McMillan. The hearty good welcome of the Leeds Camera Club was thoroughly appreciated by the visitors.

The week ended by the visit to Knaresborough on Saturday of about twenty-four members of the Convention.

"COSMOS" AT THE CONVENTION.

BETWEEN the hours of one and three o'clock on Sunday afternoon, July 12, Kirkstall Abbey, near Leeds, was almost entirely given over to the occupation of the writer of these lines. Provided with pencil and note-book, I sat where the great high altar once stood, and the only interruption I suffered in my imaginative efforts to people the ruined and restored Cistercian abbey with the monks of the olden time—to call back the glitter, the glory, and the dim religious light that once filled its stately aisles and transepts—came from a colony of quarrelsome birds that had found lodgment in its walls. I shall not soon forget that pleasant and lonely hour, for, during an eventful busy week, it was at once the most peaceful and the only one to which I was able to lay undisputed claim.

You will infer from the foregoing, dear reader, that the members of the Leeds Convention found plenty with which to occupy their time. Speaking for myself, and I believe for others, I can say that last week, for sheer, physical, hard work, would be difficult to beat in the ordinary way—that is in a week devoted to the pursuit of one's usual avocation. As an idea of what we went through, I give the tale of [my own] Friday's proceedings: Called at 6.30; 7.50 train to Ripon. Drove to Fountains Abbey. Five hours photographing and being photographed. Walked and drove back to Ripon. Lunch at 4.30. Train back to Leeds at 6.20. Arrived at 7.45. Meeting 8.30 to 10.30. Smoking concert till midnight. Then a visit to ——— But that, besides being another story, was not on the programme; so we will let it pass.

For all that, the week was enjoyable as well as bustling. They are good men of business at Leeds; and so things went without a hitch. The reception in the beautiful and well-filled picture galleries delighted the ladies, and gave them and the men the opportunity of looking their best. The civic dignitaries were affability itself, and the Deputy-Mayor (Mr. J. Gordon) pleasantly talked photography without boring us, or betraying signs that he had crammed up the article on photography in the *Encyclopædia Britannica* for his speech. The President's address gave ninety-nine out of a hundred Conventioners the opportunity of disagreeing with him, and so the week commenced in a most promising way.

Of the papers read, that delivered by Mr. Haddon, on *The Fixing and Washing of Paper Prints*, was the one that met with the greatest amount of attention. It was highly appreciated by all who heard it, as being full of sound, useful information on the subject. It was listened to with marked interest, and evoked a good discussion. One such paper, which appeals to every photographer, is sufficient to redeem a Convention meeting from the charge of doing nothing for photography. We all, or most of us, fix and wash silver prints; few of us do it properly, and Mr. Haddon tells us how it should be done. He hints at pursuing the subject, and I may therefore remind him that the Convention possesses a Research Fund of which he should take advantage.

Some fifteen or sixteen years ago a friend and I were having a humble tintype photograph of ourselves taken by the aid of magnesium, and when the operator had replaced the cap I ventured to suggest to him that the use of gelatine dry plates, which were then making headway, would enable him to shorten his exposures. Regarding me with an expression of savage contempt, he intimated, in emphatic but utterly unprintable language, that in his experience those people who knew something of photography always made the worst sitters, and he expressed bitterly ironical surprise that they condescended to be photographed by anybody but themselves. The moral of this has never been lost to me, and the incident rose in my mind on Wednesday morning of last week, when Mr. McIver, of Leeds, was taking the Convention group at the rear of the Yorkshire College.

The light was dull, the wind was blowing hard, the focussing cloths swirled and waved, one or two members thought they knew better than the photographer where they should stand, and, when the first exposure was made, somebody loudly and confidently expressed the opinion that it was underdone. Then one of the cameras appeared to be not quite level, and somebody else obligingly informed the photographer of the fact. The reply of Mr. Sellman of Huddersfield, who was assisting Mr. McIver, was simply, "Would you like to come and look for yourself?" and, not wishing to be out of the group, the interrupter was silent. Other very photographic criticisms were met by the stern request, emanating from some sensible photographer in the crowd, to "give the man a chance!" and at last the chance was given. Notwithstanding all these obstacles, a really admirable group resulted, a fact upon which Mr. McIver is to be congratulated. The background is not very picturesque, but the group contains 136 very good portraits.

The 136 members that figure in the group form considerably less than half of the total number that attended the Convention; this fact deserves mention as otherwise an erroneous idea might be formed of the attendance. Hard work, occasionally punctuated by pleasure, was the distinguishing feature of the week. Observation would lead me to think that there was far less than hitherto of that silly snap-shotting of one another in positions which, when the slides

are publicly shown, are calculated to raise a laugh or provoke ridicule. Bolton Abbey, the woods, and the river; York with its Minster, gates, walls, and other old buildings; Ripon Cathedral, Studley Royal, with the incomparably beautiful ruins of Fountains Abbey, gave opportunities for careful and well-considered work that were taken full advantage of. A crop of good results may assuredly be looked for, as the weather on the occasions named left nothing to be desired. Messrs. Watkinson's portable dark room, which accompanied us on our travels, was largely used, and a word of thanks is distinctly due the firm for its thoughtfulness.

The humours of a Convention meeting would provide matter for an entertaining book. I have only space and time for the narration of one, which gave a deal of innocent pleasure to all who figured in it. On the Thursday afternoon, in St. Mary's Abbey, York, a party of about a dozen, headed by the President, had gathered together. It occurred to somebody to have a group taken, which was done by means of a pocket Kodak. Then a member with a quarter-plate was pressed into service, and so we passed to 5×4, $6\frac{1}{2}\times4\frac{3}{4}$, $7\frac{1}{2}\times5$, $8\frac{1}{2}\times6\frac{1}{2}$, and ultimately to $9\frac{1}{2}\times6\frac{1}{2}$. In all, about ten separate photographers were cajoled, forced, bullied, or inveigled into exposing on the Presidentisl group, under the inducement of obliging Mr. Robinson, helping trade, immortalising themselves, and giving one of the party an opportunity of showing how a group *should* be taken. The confidence, the nervousness, the astonishment, the self-deprecation, the reluctance of more than one of those who were called upon to photograph groups in which such photographic notabilities as Robinson, Lange, E. R. Ashton, and others figured was most amusing to contemplate. The triumph of the afternoon was reached when two ladies were persuaded to take the group, which they did in a thoroughly cool and workmanlike manner.

The music of "broad Yorkshire;" the irrepressible animal spirits of the Leeds Camera Clubbers; the tact and distinction of Godfrey Bingley, Herbert Denison, W. J. Warren, and J. H. Walker, kept us company throughout, so that the proceedings never flagged. I have referred to the animal spirits of the Leeds Camera Club. They gave us a smoking concert one night, under the chairmanship of their President, Mr. J. Green Hirst, and the determined manner in which they set about the business of enjoying themselves and ministering to the comfort of their guests not only astonished the languid London contingent, but filled us with envy. Yorkshire folk do not appear to know what rest, repose, or sleep, means. They work hard; they play hard; and they seem to be always doing one or the other.

Some former Conventioners, such as Watmough Webster, Mr. and Mrs. Werner, Thomas Mayne, Hepworth, J. A. C. Ruthven, Child Bayley, and Mrs. Mason, were missed, but some interesting new blood put in an appearance. The late J. Traill Taylor—to whom the Convention, in its early days, owed so much—was not forgotten, as was evidenced by the vote of twenty guineas to the fund now being raised to provide a memorial to him. This was the right and proper thing to do, and the applause with which the suggestion was greeted indicated that his name will long find a warm place in the hearts of his former colleagues.

To the tale that is told elsewhere I have little more to add, except that Mr. Drage was, as usual, absolutely unselfish and tireless in ministering to the wants and wishes of the Conventioners. He was wholly unsparing of himself, and if ever a man toiled hard for other people, and met with success in his single-minded efforts, that man was Drage. With the assistance that he is entitled to receive, it is to be hoped that he will guide the Convention for many years to come.

To sum up, the Leeds Convention was an all-round success. Everything was of the best; the attendance, the papers, the weather, the places visited, the harmony, and the dinner; while good fellowship reigned throughout. At the beginning of the week a little cloud appeared on the horizon, but the wind changed, the sun burst forth, and the rest of the week was bright and fair. And so good-bye to grimy, smoky, noisy, bustling Leeds, and the enjoyable, earnest, thoroughgoing Convention of 1896.

The last four non-Leeds Conventioners remaining in the town on Saturday afternoon made their way to the 5.30 express for London, pleased and tired with their week's experiences. When the train started, one of them softly removed his Convention badge from the lappel of his coat. "Is the Convention ended?" asked a second, in a tone of voice expressive of surprise at the rapidity with which the week had gone. The others nodded, silently and somewhat sadly, and then the mighty express sped on its way south. COSMOS.

ON THINGS IN GENERAL.

I HAVE been considerably interested of late in scanning The Inquirer columns of this JOURNAL and have come to the conclusion that they meet a long-felt want, and, though I do not go to the extent of saying that no photographic home is complete without them, I do think they will be found very useful to a large number of readers. I must, however, say that the very least compliment that could be paid to those who reply would be to read the replies before asking for further information. I am led to make this remark by the query of "Billericay," who wishes to know if it is a fact, as asserted last week, that an insoluble chromate of silver is formed by the action of bichromate of potash on carbonate of silver. He goes on to show that his experience is contrary to the substantiation of such fact. Now, if "Billericay" will only go to the trouble of reperusing the replies on this subject, he will find that the exact converse of his alleged fact is set down.

With regard to "Perplexed" and others writing about iodine in solution there is all the necessary information for practical purposes, but not a definite explanation of his original difficulty. The truth is, the "tincture of iodine" of the pharmaceutist is not a simple spirituous solution of iodine, but a solution made by the addition of iodide of potassium to the extent of fifty per cent. by weight of the iodide employed. It is the presence of this potassium salt that prevents the precipitation when the tincture is added to water. When a solution of iodine is needed for stock—and it is a most desirable preparation in any photographic establishment—the simplest way to make it is to rub up some iodine in a mortar with a little water, and add a few crystals of iodide of potassium, and keep on stirring till the iodine is all dissolved, adding a further supply of crystals if necessary. This is an invaluable solution for removing silver stains from the hands or linen. Apply the solution, followed by a solution of cyanide of potassium. Any silver stains, however old, will give way to this treatment, which may have to be given a second time if the stain be very strong or the iodine solution not strong enough.

The event of the week—the event of the year, I may say—is past and gone, and the Convention of 1896 is the most illustrious of any, if mere numbers count. What very mixed feelings our worthy President's address must have raised! but the genial way in which he trod on people's corns robbed it of all offence. When, in the early part of his address, the President repeated the *bon mot* of a camera club man, "What is photography?" he scored a point; but he rather gave himself away afterwards in his plea for pure photography, for, when any one fresh to the subject views the annual exposition of the works of the Linked Ring, What is photography? is the very question that arises in his mind. *C'est magnifique mais ce n'est pas la photographie*, if I may be pardoned the liberty I take with a celebrated saying. Mr. Robinson says, "In the science of photography we soon find, with Macbeth, that 'nothing is but what is not.'" An equally fair quotation could be made from the Brothers James and Horace Smith's inimitable parody, when Photography and the New Photography were compared and discussed in the dim seclusion of the Salon: "Nought is everything, everything is nought, and thinking is but waste of thought."

By the bye, why does our most esteemed photographic stalwart of the stalwarts appropriate the term "The New Photography" to the Salon and all its works? I have a very distinct recollection of

seeing an advertisement of a professional photographer—years before the genesis of the Salon, headed "The New Photography."

What a charming picture is drawn in the address of the "public rush for the quiet simplicity of those portraits which appear to be almost too simple to be art, but which are all art, that have been shown to you in the Salon." Unfortunately the rush for photographs is a thing of the past to most people, and to suggest that business would be improved by avoiding retouching is to suggest the arrival of the millennium and the sudden surcease of vanity. It is retouching, however degrading it may be—and too often it is a vile degradation—it is retouching that has kept professional portraiture alive, sad though it may be to state it. What became of the arch-priests of photographic purity when retouching became general? They either sank utterly, never to rise, or, after a brief struggle, frantically stuck to retouching as the only lifebuoy. Talk of Silvy as a specialist! there is nothing special in charging two guineas for forty *cartes-de visite*, and, in his day, little but *cartes* were asked for. He and Salomon were men of great artistic taste, which permeated and distinguished all their work. What greater specialist or worker of more artistic feeling than poor Rejländer? And what did he make out of it? The thing necessary above all to make photography a paying profession is business talent. Silvy had a happy combination of both, and he made it pay handsomely. Some of the most wretched samples of, what I suppose, must be called photography were sent out of his studio, and some of the most beautiful.

To make a good thing out of professional photography is very rare nowadays, and, notwithstanding the editorial dictum about small and moderate businesses, I feel no hesitation in saying that a man who takes, say, 500*l.* a year, working it entirely himself, with perhaps a young girl to be useful to see clients, will make a bigger income than one whose receipts are three times as much, with the concomitant necessary assistants, and larger premises, and general expenses. I have at this moment in my mind's eye the example of a photographer in one of the Channel Islands, not to be too precise. He is a splendid worker. He takes all his sitters himself; prints, tones, mounts, and despatches every print, and deems himself passing fortunate if he takes two sitters a day. That man's receipts are pure profit within twenty or thirty per cent., while the "pro." is an exceedingly lucky man if, with gross receipts of three times 500*l.*, his *profits* reach twenty or thirty per cent.

One of the meanest pieces of photographic sharp practice is that referred to in last week's Ex Cathedrâ, where a local photographer, in supplying a series of views for publication, calmly appropriates another photographer's work by copying it, and sending the copied print with the pirate's name as author. The editor speaks of the possibility of a jury accepting the probability of a coincidence accounting for two different pictures appearing alike. That is possible, for the ways of the juror are beyond account. Fortunately, however, there is another mode of procedure, which would give absolute and irrefragable proof. Let each of the two photographs be copied to an exactly similar size, and mounted as a stereoscopic slide, a deviation of a straw's breadth in the position of barrow, man, or broom, would be startlingly evident if the slide were viewed in a stereoscope. I present this suggestion to the injured original photographer.

It is satisfactory to see attention given to the question of fading again, by so eminent an authority and accurate experimentalist as Mr. Haddon; but I would commend to his notice the question of mounts. I have evidence which, to me, is amply sufficient that an immense amount of fading is due solely and wholly to some fault in the mounts (not the mounting); mounts, too, that have no right to be faulty, if their cost is to be any criterion. This is a question of the highest importance, and will force itself to the front eventually.

FREE LANCE.

DAVEY'S SYSTEM OF EMBOSSING PORTRAITS.

MR. WILLIAM DAVEY, of 66, Truro-road, Wood Green, describes this invention (a communication to him by Frank Davey, of 121, Post-street, San Francisco, photographer).

It has for its object to increase the lifelike appearance of photographic portraits by embossing the parts of the print corresponding to the features, figure, dress, and accessories, in bas-relief, so that the effect of the photographic high lights, half-tones, and shadows will be enhanced by actual modelling of the surface of the photograph.

"In order to emboss a portrait, I either produce directly upon a suitably prepared wood block a photographic print from a transparency which has been made from the same negative as the print to be embossed, or I transfer to the wood block a celledion film or a single transfer carbon print, or a thin gelatine film, or a traced outline from the same negative or from a print produced from the same negative, the object, in any case, being to produce upon the block a more or less perfect outline of the portions of the portrait to be embossed, the relative position of the parts being reversed, as regards right and left, to serve as a guide to the carver in the subsequent operation. I then carve the wood-block so as to produce an approximately correct counterpart in intaglio (reversed as regards right and left) of the features and other portions of the picture to be embossed, the depth of the carving being approximately proportional to the natural relief and rotundity of the parts of the subject represented.

"The photograph print to be embossed, having been mounted upon a thick soft paper which will adapt itself readily to the die and permit of embossing in relief without splitting, is generally damped before being embossed, especially if the relief is to be considerable, except in the case of carbon and gelatine prints, which would be liable to adhere to the die if damped, and must therefore be embossed dry.

"The mounted print is then subjected to pressure, in a screw or other press, between the carved die and a soft rubber pad, or a counterpart in cameo, the face of the print being in contact with the intaglio die, and due precautions being taken to ensure correct register between the die and the photograph. With this object in view, I trace an outline from the negative and apply it in correct register to the die, and drive register pins through the tracing into the marginal portions of the die. I then remove the tracing and apply it in correct register to the print, and perforate the print through the holes in the tracing. The mounted and perforated print is then placed on the die, the pins coming through the perforations keeping the print in proper register.

"The counterpart in cameo may be an easily mouldable material such as paper pulp, or a pad of soft, elastic indiarubber which adapts itself to the configuration of the die at each pressure, and may serve for dies of different forms. In order to obtain a perfect impression of the die, the print may be first pressed with a soft pad, such as referred to, and then subjected to a second pressure between the same die and a counterpart formed of guttapercha which has previously received the impression of the die in the press. The print should be left under pressure for about ten minutes, or (especially if pressed dry) until it has permanently acquired the configuration of the die, and, after being removed from the press, it should be mounted in a deep *passe-partout*, or other frame, which will protect the relief surface of the print from injury. It is also preferable to back up the embossed parts of the print with cotton-wool, and to mount it on a stout cardboard backing."

The claims are:—

1. The described method of embossing photographic prints in relief by pressure between a correspondingly carved die and a suitable pad or counterpart.

2. A photographic print embossed or modelled in relief.

Our Editorial Table.

RADIOGRAPHY AS AN AID TO DIAGNOSIS is the title of a pamphlet by Dr. Hall-Edwards, of Birmingham, in which the author, an ardent radiographic worker, quotes cases upon which radiography has thrown considerable light, and has aided the diagnosis. The pamphlet, which is reprinted from the *Birmingham Medical Review*, appeals to surgeons, who, doubtless, will appreciate it, as it is replete with useful suggestions.

MARION'S CATALOGUE FOR PROFESSIONAL PHOTOGRAPHERS.

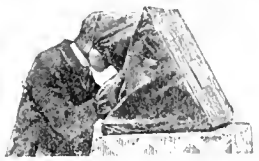
Marion & Co., Soho-square, W.

THE section of Messrs. Marion's catalogue which contains particulars of goods primarily intended for the use of professional photographers is before us. Accessories in great variety, backgrounds, show-cases, mounts, show-screens, and numerous other requirements of the professional man are described and illustrated in the course of a hundred pages. It is a well-got-up volume.

The Simplex Changing and Developing Tent.

F. Beresford, 14, Bridge-road West, Battersea.

Mr. Beresford has shown us his latest production — a tent, primarily intended for developing on emergency, but also capable of being used for changing purposes. Two metal uprights and a cross piece support the fabric, which is secured by stout elastic to the bottom of the box, forming the base, so that no light can enter.



There are large holes for the arms, and an elastically bound face hole fitting just beneath the nose, and so allowing one to breathe freely. When set up, the tent is nineteen inches high, and gives a working space of twenty-two inches by sixteen. Folded up in its box, the measurements are eleven by sixteen by three inches. Three thicknesses of material are used, and perfect light-tightness should therefore be obtained. The Simplex struck us as being a useful and practicable tent.

The Roman Ruins at Darenth.

Mr. J. H. Baldock, of the Croydon Microscopical and Natural History Society, has kindly sent us two photographs of the Old Roman Villa at Darenth, which he took on the occasion of the Society's photographic outing there a few days ago. The photographs are excellent.

Photo-Autocopyist Specimens.

The Autocopyist Company, 72, London-wall, E.C.

We have received from the Autocopyist Company some specimens of collotype printing done on the simple hand-worked apparatus that has been frequently described in these pages. Appropriately enough, having regard to the Leeds Convention, one of the views is of Kirkstall Abbey before its "restoration." This and the remainder of the specimens are remarkably good examples of this simple system of ink printing, which deserves to achieve wide popularity by means of the Photo-autocopyist. Rough surfaces and variously coloured inks are employed with equally happy effects.

News and Notes.

Paper for Photographic Purposes.—Mr. F. F. Weeks writes: "*Re* answer to correspondent, T. Coombs, page 464, I note your answer. But why not an English firm start making a special paper of A1 quality and various grades for photographic purposes? Surely there is a big opening for such a line. We have some famous British paper-making firms; it ought to be worth their while to make the trial."

Errata.—Owing to absence from home at the time of publication of our last issue, some errors escaped notice until too late for correction. In the last paragraph of leaderettes on page 452, last line but one, "controverts" should read "corroborates," which exactly reverses the meaning; but, as we have for many years consistently condemned "eliminators," we have little doubt from the context most of our readers will have recognised the mistake. Mr. Bothamley is made to speak of Mr. Haddon's four "pages"; "papers" was meant, of course.

Practicable Application of Acetylene.—At a garden party held on Saturday, the 11th inst., at Camberwell, S.E., the lawn was brilliantly illuminated by acetylene gas. The generators and fittings were supplied and fixed by Messrs. Thorn & Hoddle, inventors and manufacturers of the Incanto acetylene gas generators. This is, we believe, the first occasion on which this light has been applied in such a practical manner. The light was exceedingly brilliant, and illuminated the spacious lawn (on which dancing was being enjoyed by about five hundred persons) in a manner that would favourably compare with an elaborate electric-light installation.

For etching letters, names, or designs on metallic goods, such as knives, for instance, the *Zeit. f. Electrochem.* gives the following directions:—The objects are covered with the following mixture: 1 litre of naphtha, ½ kilogramme of carbon bisulphide, 2 kilogrammes of pulverised resin, and 1·5 kilogramme of chloride of copper. After covering with a thin layer of this, the stencil or type is washed with a weak solution of potash and pressed on the surface, which is then washed, after which it is wetted with a weak solution of sal ammoniac, through which a current is passed, which then etches the metal where the insulating coat has been removed.

On Saturday, July 11, the *employés* of Messrs. Penrose & Co., Upper Baker-street, W.C., the well-known manufacturers and dealers in process-work appliances, had their annual outing. The party, numbering twenty-five, proceeded by train to Hampton Court, and thence by steam launch up the river to Chertsey, where luncheon was served. Mr. A. W. Penrose presided, and, in responding to expressions of goodwill and thanks from the staff, said he fully hoped to see double the number around him next year. Cricket and boating were afterwards indulged in, and the party, having partaken of tea, started about seven o'clock on the return journey, which was beguiled by some excellent songs and music from various members of the staff

An Optical Illusion.—While doing some photographic work with a light from a Welsbach burner, which shone through a small ground-glass window in a dark room, I noticed that, when a lamp emitting red rays from its vertical sides was placed in a position so that its top was illuminated by the white light from the window, and while in this light it was then moved by hand to and fro in a horizontal plane, the top appeared to be loose, or displaced in opposite directions to the red sides. The top was of bright tin, and its surface sufficiently irregular to cast slight shadows, which rendered the effect very marked. This illusion is, no doubt, due to a physiological action at the retina, in which the impression produced by the white or grey light persists longer than that from the red, causing an apparent lag of the top. The persistency may be still further accounted for when the fact is borne in mind that the lag could only be obtained with weak lights in a dark room, and therefore with the pupil of the eye largely expanded, and in consequence a relative increase of intensity of the white over the red light upon retinal areas of different sensibility. Lamplight or daylight can be used instead of a Welsbach. I found it convenient to vary the intensity and colour of the lights by superposing sheets of coloured tissue papers.—F. H. Loring in *Nature*.

The Commercial Value of Applied Chemistry. — Professor Dewar's recent lecture at the Royal Institution was a rapid survey of the galloping pace at which chemical discovery of value in the arts has lately proceeded, says the *Chronicle*. It was a complete justification of Mr. Ludwig Mond's dictum, that chemical research spells commercial success. Take, for instance, what Mr. Mond himself has brought to light and utilised, all through his attempts to improve the gas battery first invented by Lord Justice Grove. Why cannot we turn coal directly into electricity without the cumbrous boiler, steam engine, and dynamo process intervening—burn it up as you burn up zinc in a galvanic battery? Well, the idea is very magnificent, but not yet within the range of practical science. But the suggestion that carbonic oxide might be used in some way led Mr. Mond to discover a strange and totally unexpected property of this gas, namely, that it will directly unite with metallic iron and nickel to form gases which are called carbonyls of these metals. Could anything be more strange than the idea of iron as gas at an ordinary temperature? And could anything be more valuable, for, as soon as you heat these carbonyls, they give out the metal again with the greatest facility? The result is, that Mr. Mond is now using carbonic oxide to extract nickel from its ores. He gets nickel carbonyl as a gas, subsequently heats it to make it part with its nickel, and sends back the carbonic oxide to extract some more. In this way pure nickel can be obtained, for the gas will only pick up the nickel. Professor Dewar also described the famous Castner process for getting pure soda from common salt. Here we have electrolysis at work once more, but with a movable electrode in the shape of a flowing stream of mercury, which bears away the metallic sodium in amalgamic solution as fast as it is separated from the salt. The amalgam then passes into water, where the sodium dissolves as hydrate, leaving the mercury free to go round again. But there is something more than this. As the sodium dissolves, it generates electricity. Formerly this electricity was generated in the electrolytic bath itself, and obstructed the operating current by setting up a "back current" on its own account. Now, the "back current," being separately generated, is made to travel the right way, and supplement instead of obstructing the working current. Finally, Professor Dewar illustrated the discovery of the effect of the oxides of the rare earths, such as those of zirconium, thorium, and lanthanum, in transforming heat into light. This is the principle of the incandescent gas burners. The now familiar mantle, which is suspended in an atmospheric or Bunsen burner, and glows so brilliantly, is made, as Professor Dewar showed, by saturating a cotton mantle with salts of these metals and then incinerating it. The organic cotton is all burned away, leaving nothing but a skeleton mantle of oxides and silica. When these are suspended in the colourless gas flame, they glow in the brilliant fashion now so familiar, far surpassing the incandescence which can be obtained from platinum, magnesium, lime, and other substances heated to the same point.

National Association of Professional Photographers.—The summer meeting of the N.A.P.P. was held this year in connexion with the Photographic Convention, Leeds. The Association attended the reception by the Mayor of Leeds in the City Art Gallery, and all the various excursions, meetings, dinner, &c, with loyal devotion to their "badges" as members of the 1896 Photographic Convention. The business meeting during Convention week was held at the Imperial Hotel, Leeds, headquarters, as on the previous occasion of the N.A.P.P. Mr. Barry (Hull), President, in the chair. Amongst those present were Messrs. T. Fall (London), Harold Baker (Birmingham), J. Davis (Lancaster), Boak (Driffield), E. J. Walker (Maybole, Ayrshire), Priestley (Egremont), Eddison (Leeds), Crosby (Rotherham), Freke (Cardiff), and R. Stewart (Elgin, N.B.). Amongst other professionals who joined in the Convention were Messrs. Warwick Brookes (Manchester), W. Crooke (Edinborough), J. Stuart (Glasgow), and T. Birtles (Warrington). The Hon. Secretary, Mr. T. Bromwich (Kidderminster) was absent through illness. Letters of apology for non-attendance were received from nearly fifty members of the N.A.P.P., all expressing extreme regret at being unable for various reasons to be present, and wishing their professional brethren "a good time and good weather." The annual report referred to the very pleasant summer meeting held last year at Matlock, and the special courtesies extended to the N.A.P.P. by His Grace the Duke of Devonshire when visiting Chatsworth House. Over 100 professional members are enrolled on the books of the Association, and it is in the happy position of having funds in hand. Messrs. Charles Speight (Kettering) and E. J. Walker (Maybole, Ayrshire) were elected as new members. Some resignations were reported. Mr. Harold Baker (Birmingham) submitted some skilful photogravures, of his own production, which are intended to illustrate a work he is preparing upon the Avon district and Shakespeare's land. Mr. T. Fall (London) gave the brethren a treat, by showing some of his inimitable photographs of dogs—as he said, with his Yorkshire humour, he was only a poor photographer, and had nothing to show but photographs of dogs and donkeys. The announcement of the death of two old members of the N.A.P.P., Mr. Jesse Holloway (Cheltenham) and Mr. Adamson, sen. (Rothesay), was received with profound

regret. The usual dinner and London meeting had been held, November 9, at Anderton's Hotel, Fleet-street, at which the opinion was expressed that the past action of the N.A.P.P. had resulted in a very definite improvement in the terms allowed to professional photographers, and the publication of lists for the trade, and the trade only, where formerly no such lists were issued or even named. Mr. Hubert's proposal to amalgamate the Photographers' Benevolent with the N.A.P.P., had not received the approval of the Council. Referring to Mr. J. A. Draycott's suggestion as to professional photographers acting on the same lines as the Printsellers' Protection Association, it was considered that the circumstances and details of the two trades were so essentially different, as to prevent any action in the direction suggested. The Secretary (Mr. D. J. O'Neill, Birmingham) drew attention to the present unsatisfactory condition of the law of photographic copyright. Hope was expressed for a proper and authentic codification of the confused and conflicting legal enactments, which are a source rather of doubt and difficulty than of security and protection to the profession in many cases. The next meeting of the N.A.P.P. will be held on the Monday following the opening night of the Royal Photographic Society of Great Britain and Ireland, expected to be September 28.

Patent News.

The following applications for Patents were made between July 8 and July 15, 1896:—

Photographic Apparatus.—No. 14,972. "An improved Camera, Dark Slide, and Changing Bag for Photographic and other Sensitive Plates." M. Stephens.

Cameras.—No. 15,154. "Improvements in or appertaining to Photographic Cameras." J. Gaoe.

Screen Kinetoscopy.—No. 15,155. "An improved Chrono-photographic Apparatus or Motograph." Complete specification. J. Rous.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

July.	Name of Society.	Subject.
27	North Middlesex	Demonstration on Sandell Plates. J. T. Sandell.
28	Birmingham Photo. Society	Excursion: Astley, South Warwickshire. Leader, W. Jones.
28	Hackney	*Intensification and Reduction.* E. J. Wall.
29	Oldham	Excursion: Rossett and Gresford. Leader, J. S. Dronsfield, J.P.
29	Photographic Club	The Management of a Photographic Society.
30	Birmingham Photo. Society	Last Day for Sending in Competition Pictures for June Excursions: Arbury, Compton Wynyates, and Stokesay.
30	London and Provincial	*Under-exposure, and How to Make the Most of It.* J. E. Hodd.
August.		
1	Borough Polytechnic	Excursion: Streatham and Beddington.
1	Darwen	Exc.: Hollinshead Hall and Rocky Brook District. Leader, Albert Almond.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

July 16,—Mr. T. E. Freshwater in the chair.

Mr. Edwin Banks was elected a member.

Mr. Ashby showed a photo-micrograph of a diatom magnified to about eight hundred diameters, the many different planes being very sharp. The objective used was of one-sixth inch power.

Mr. Bayston inquired what was an easy way of calculating the angle shown by any lens on a plate of a given size.

The Hon. Secretary referred Mr. Bayston to an article and tables of his on page 664 of The British Journal Photographic Almanac for 1894, which gave a very simple method, adopted by Professor Burton and the leading Continental authorities, and which was also the mathematical way of doing it. A 5½-inch lens on a 8½×6½ plate would include an angle of about 88°, that is when using the lens in the centre of the plate, but by shifting the lens to one side the angle is altered.

In a short discussion on the latest developments of the Röntgen-ray photography, the Chairman said he had found that those plates that were more sensitive to the X rays were also more sensitive to the photographic rays. He had failed in the use of a gelatine dry plate as a fluorescent screen, as suggested recently.

The Hon. Secretary said it had been shown that collodion plates which were not fluorescent were useless for radiography, while gelatine plates, which were fluorescent, were sensitive to the rays. He thought it would be interesting to know whether a more fluorescent gelatine would produce a more sensitive dry plate.

MANCHESTER PHOTOGRAPHIC SOCIETY.

On Saturday, the 11th inst., twenty-four members and friends assembled on London-road Station about 1.15. The event was the second outdoor meeting of the season, and the weather, like the last excursion, was perfect. The train left punctually at 1.30, landing the contingent about 2.15 at Chelford. After a short walk, a shady road was reached which led down to the church, which edifice being so surrounded by trees made it unphotographic. Turning to the right, and presenting our credentials at the lodge, we enter the park of Astle (permission being kindly granted by the owner, Colonel Dixon), where cameras were soon at work on the rush-lined shores of the mere. Nearing the hall, a refreshing sound of falling water tells us that we are near the waterfall, and several plates were exposed on it, seen through the arched bridge. About five o'clock the party collected together, and walked by lane and field to Nether Alderley, where tea was partaken of at the Eagle and Child Farm, after which those members who had the fortune to have some plates left, exposed on haymaking scenes, the church and rectory, and many other subjects. The usual group was taken in the churchyard, and, after a pleasant walk to Alderley, caught a most crowded train back to Manchester, arriving about ten o'clock.

North Middlesex Photographic Society.—July 13, Mr. Mattocks in the chair.—Mr. Milne gave a demonstration on

Venus Paper.

The lecturer began by passing round some prints, showing what could be done on the paper, the prints being of various grades of surface, from rough to smooth, and exhibiting a great range of colour. Mr. Milne then toned some prints in the Venus combined bath, which gave very pleasing brown tones, and also toned one to a platinum black by immersing it in th Company's No. 1 bath to a warm purple shade, which changed to black i the combined bath. He also toned some in a platinum and nitric acid bath which gave a pleasing warm brown tone. He recommended the addition of borax to the fixing bath:—hypo, 1 ounce; borax, ¼ ounce; water, 20 ounces. The prints toned in the combined bath required further fixing in this solution, as the action was very quick—about one minute is sufficient. Mr. Gosling asked if a partially printed proof could be developed up. Mr. Milne said Yes, and recommended hydroquinone. Several further questions were asked and replied to, and a vote of thanks passed to the lecturer.

South London Photographic Society.—The last meeting of this Society was devoted to a Beginners' Night, when the Hon. Secretary (Mr. Oakden) dealt with the subject of Cameras, their forms and accessories. After explaining the advantages of various cameras, he went into detail as to the uses of the various movements, and also as to how and when they should be utilised. Lenses and their different forms received their share of attention from the lecturer, who explained the advantages for certain purposes of some forms over the others. A camera stand should, above all things, be light, with sufficient rigidity to prevent the apparatus moving during exposure. A stand which was not rigid was a nuisance.

Correspondence.

☞ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

THE CONVENTION OF 1896 AT LEEDS.

To the Editors.

Gentlemen,—The Leeds Convention is at an end, the treatment that has been meeted out to us by our Leeds friends will make the period of our stay in the district a not easily to be forgotten week.

First and foremost the President's address, and the valuable papers and demonstrations (attendances at which have been very large) have supplied us with ample food for our minds during the week.

We have had placed before us an inexhaustible stock of food for our cameras (considerably over 3000 plates and films, ranging up to the lordly 12×10 and 15×12, having been exposed during the three principal excursions), while the arrangement for food for our bodies have been practically faultless, owing to the care and forethought of the local Executive Committee.

There were 305 subscribers, 209 signing the attendance roll, a large increase on former numbers of Convention.

Mr. Godfrey Bingley, the local Hon. Secretary, on whom great responsibility has rested, and on whose labours the success of the Convention so largely depended, deserves the heartiest thanks of every member of Convention; may he long be enabled to devote his *special* gift of organization for the benefit of his fellows.

Our reception at the City Art Gallery will long be remembered by those who attended; and to Mr. Herbert Denison, the local Hon. Treasurer, we all owe our best thanks for his labours in arranging such a very pleasant function, and also to the other members of the local Executive committee, the Chairman of which, Mr. John Henry Walker, by his tact, urbanity, and good fellowship, has done much to make our visit to Leeds so very enjoyable.

At the annual general meeting the members decided to vote twenty guineas of the Convention funds towards the Traill Taylor Memorial Lectureship Scheme.

A very cordial invitation to make Great Yarmouth our centre for the meeting of 1897 was accepted unanimously.

Mr. F. P. Cembrano was elected President of the Convention for the year 1898.—I am, yours, &c., R. P. Drage, *Hon. Sec.* (*pro tem.*).

Photographic Convention of the United Kingdom.

VARIOUS SUGGESTIONS.

To the Editors.

Gentlemen,—Your valuable Journal is always received with thanks. I wrote to you some time ago to have an explanation in regard to a

certain kind of halation, but have had no answer as yet, and all parties I have shown it to were unable to explain. I therefore must give it up, for the time being at least. On June 12 last, in your Correspondence, Mr. Charles H. Hewitt refers to his way of using the air in developing a plate. This is not quite new, as it was known to me and to others, as I am not the discoverer, over fifteen years ago, and even now it is a great help to me. While developing the plate, I lift it out occasionally, and, while looking at it, I leave it in the air some time, when the intensity increases more rapidly than otherwise, while an occasional good rinsing under the tap hastens the development also. I have even found lately that a plate, when fully developed, intensifies somewhat when left, say, ten to fifteen minutes under the tap before fixing in hypo.

On June 19 last, page 385, "A Suggestion for Overcoming the Crackling Tendency," &c., is not quite new either, as the explanation of such a contrivance was given by me at some length in your ALMANAC of three or four years ago.

A few weeks ago one of your correspondents complained of the irregularity of the ready-sensitised paper. I have had some trouble in the same line, but not so much lately as formerly. If the paper is badly prepared (as I do not think the trouble lies in the paper itself), that is, in the albumen or in the silver bath generally in such cases too weak, the remedy is scarcely possible, except one is satisfied with a very light purple tone, but never a black tone can be approached. I have lately found, however, that the results can be improved in a very simple way. I must, however, at once say that the method I use seems not only childish, but almost ridiculous; but I give it to you for what it is worth, and it may be followed or not. I, for one, am satisfied with the results.

When about to tone (I use the bicarbonate of soda and gold bath), I prepare my bath about fifteen or twenty minutes beforehand. This time may be lengthened to one hour, but I don't like to shorten it. Now, if I make a toning bath of, say, sixteen ounces of water with proportions of bicarbonate and gold, to tone 100 10×8 inch prints, I may succeed in obtaining a good tone and rapid toning, but sometimes I do not. My proportion of very good results is more certain when I prepare the same necessary quantity of gold and bicarbonate in about three or four ounces of water; then let it rest as above, and add the required quantity of water just before using the bath. I cannot explain the why of it, but this is my experience.

I see also in one of the later numbers of THE BRITISH JOURNAL OF PHOTOGRAPHY parties finding that the bicycle harms the camera business. This may be so, but the camera man is to blame for a great part of this lack of interest. I have advised the manufacturers of cameras to devote some attention to the making of a light and compact folding camera, and then the bicyclist may carry one along, otherwise he will be apt to leave it at home. Of course, some manufacturers will say that they have such a one for sale, and that it is all that can be desired; but ten to one that, if he is a cyclist himself, he does not use his own instrument, and, if not a cyclist, he is no good judge. The camera, if carried at all, should be inside the frame, between the legs, and the tripod, if any, across the guide or steering. The cameras, as made now for such purpose, are too heavy, when complete, with rising front and swing back, &c., or too clumsy, or otherwise too flimsy to resist any shaking during the outing, and the wind, however slight, during exposure.

Give us a camera of 5×4 or 7×5 plates, strong, light compact, and complete, to fix inside the frame, and I dare say a ready sale will reward the manufacturer, as the instantaneous boxes are, however light, always clumsy, and, as long as one has to stop cycling to take any view, he may as well have a good one, and correctly exposed and focussed, to have a better result, specially for enlargements.—I am, yours, &c., A. LEVY.

Asnières, Seine, July 16, 1896.

DEVELOPING FORMULÆ.

To the EDITORS.

GENTLEMEN,—We are so heartily in accord with your views as to the unsuitability of many developing formulæ for the ultra-rapid plates of to-day, that we gladly welcome the leading article on the subject in your issue of the 10th instant.

When the great increase of speed of plates was attained, we at once found the grave risks which such speed involves in the matter of development, as so forcibly pointed out by you, and, after careful experiment, we decided to adhere strictly to our then developing formula—pyro soda—*which is perfectly safe to use with even such ultra-rapid plates as the Ilford Special Rapid series.*

Not only is this formula perfectly safe for these plates, but it is one that brings out all possible detail, and thus admits of the shortest possible exposures.

The risks arising from using our developing formula are therefore *nil*, but there remain the further risks due to the use of formulæ other than our own.

To draw attention to this matter, and to minimise the risks, we have, for some time, added the following warning on our Special Rapid labels:—

"Developing Formula.—Special Note.—For Ilford Special Rapid plates the following is the most suitable, and the only one we recommend."

—We are, yours, &c., THE BRITANNIA WORKS COMPANY, LIMITED.

Ilford, London, E., July 21, 1896.

DIRECT HALF-TONE NEGATIVES.

To the EDITORS.

GENTLEMEN,—Mr. W. Gamble, in his "Photo-mechanical Notes" in THE BRITISH JOURNAL OF PHOTOGRAPHY, of May 29, 1896, refers to taking direct half-tone negatives from life, and points out the great advantage it would have over the present mode of making half-tone negatives from prints, and the great saving in time for producing blocks for newspaper illustrations, &c.

I have given this matter my serious attention for a long time, and have at last succeeded in making what I may call direct half-tone negatives from life, snap-shots not excluded. I enclose a few copies of a negative produced by my process, so that you may judge for yourself. The copies are produced in collotype, as I have no convenience for making half-tone blocks.

I shall esteem it a favour if you will be good enough to put me in communication with Mr. Gamble, as I should like to see him on the subject, and hear his opinion.—Thanking you in anticipation, I am, yours, &c., E. FENSKA.

19, *Rockbourne-road, Forest-Hill, S.E., July* 20, 1896.

[The results our correspondent encloses are promising. In all probability this letter will come under the notice of Mr. W. Gamble, who will, doubtless, communicate with Mr. Fenske direct.—ED.]

MOVING PICTURES ON THE SCREEN.

To the EDITORS.

GENTLEMEN,—Referring to the paragraph in your issue of July 17, under the head of Ex Cathedrâ, in which your correspondent says, *apropos* of Mr. Friese-Greene's letter in last week's issue, that "every one seems to have entirely overlooked Muybridge in this connexion." Now, it appears to me that Muybridge's methods and results do not bear upon the present controversy at all. In the first place, I think you will find that his pictures were not taken with one camera, but with a series of cameras taking one picture each; consequently they were not taken upon a continuous travelling film, neither were they taken from one point of view—they were, in fact, a number of detached photographs upon glass. The pictures were afterwards printed, in series, upon a glass disc, which was made to revolve in a lantern, the result being a sort of modified zoetrope, in fact the only difference I can see between Muybridge's apparatus and the old "wheel of life" is that the pictures were shown on a screen instead of being viewed through a slot. The essence of Mr. Friese-Greene's invention consists in the taking of the pictures upon a continuous film, in *one* camera, and in projecting them, intermittently, from the same or similar apparatus upon a screen. The comical episode your correspondent refers to sufficiently fixes the difference of method and result, as it would be absolutely impossible to get a similar effect, or anything like it, from Mr. Friese-Greene's apparatus. I take it that Mr. Friese-Greene does not claim to be the inventor of the zoetrope, but of a camera for taking photographs upon a continuous band at a rapid rate, and of an apparatus for projecting them upon a screen so as to produce a lifelike effect, and his claim certainly appears to be unassailable.—I am, yours, &c. T. H. BETHELL.

Parliament Mansions, Westminster, July 20, 1896.

THE SALE OF PHOTOGRAPHIC BUSINESSES.

To the EDITORS.

GENTLEMEN,—Your leader in last week's JOURNAL, touching the purchase and sale of photographic businesses, is one that all professional photographers should be interested in, and, although it is admitted that no fast rule could be arranged for the disposal and purchase of all businesses alike, there are still many points that are general to any business and might, with advantage, be more carefully observed by both purchasers and vendors of businesses. I think one of the first inquiries a purchaser should make, and insist upon, is a *balance-sheet* of the business, showing the profit and loss of the undertaking for the past three years. It may be argued that photographers are proverbially bad bookkeepers, and that to make a balance-sheet would be a difficult matter in most cases, but I contend that a photographer, having anything to sell worth selling, would be consulting his own interests, as well as the purchaser's, by calling in a respectable accountant and having a sheet properly prepared, the cost of which certainly should not exceed one per cent. and the same would enable him to fix more accurately the value of his business. A second inquiry a purchaser should make, and again insist upon, is an inventory of the instruments, furniture &c., and an account of the stock in trade, and I think, fortified with these primary particulars, any man finding himself taken in with a business would have no one but himself to blame, and certainly would have no redress in a law court. Your remarks in reference to the caution required with regard to the lines a business has been run upon do not, to my mind, contain as much importance as would at first be impressed, unless the business is in a very small place, where the population is not actually growing; for I am under the impression that, where the town is large enough, you can no more exhaust the demand for photographs than you can that for clothes, boots, &c., for each year brings forward its rising generation, full of the same vanity as its predecessors. What must not be lost sight of by the

new proprietor of a business is resource within himself, an ability to adapt himself to his new surroundings and cultivate new ideas to attract the public, &c. Your remarks in reference to the employees of a new business not being "bound over to keep the peace" is a very pertinent one, and the purchaser of a business should partly base his valuation on the probability of such a breach taking place, particularly if he is paying anything for the goodwill of the business. In conclusion, I will also refrain from making any estimate of the valuation of businesses, but attention to the suggestions made above cannot fail to prevent disappointment where ordinary care is taken.—I am, yours, &c., NOSILLA.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & Co., 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:—

Henry Dunning, Bridge-street, Usk, Monmouthshire.—*Photograph of Colonel Burton on horseback at brigade inspection.*

Edward Adolphus Tear, 5, Westgate-street, Ipswich.—*Photograph of Charles Barnard Westley, Champion of Suffolk, on bicycle.*

Debenham & Co., 5, Clifford-street, York.—*Photograph of the Lord Mayor of York, Mr. Alderman Milward, in robes and chain, three-quarter length profile. Photograph of the Lord Mayor of York (large head), Mr. Alderman Milward, in robes and chain.*

STRAINING.—N. B. (Burton-on-Trent. 1. Ordinary chamois leather. 2. Nainsook, as sold by all linendrapers.

THE RÖNTGEN RAYS AND CONSUMPTION.—H. R. SHARPLES. Your doctor was quite right; the X rays are not germicidal.

ONE OF OUR ADVERTISERS.—You omitted your name and address. We do not answer such questions as yours, viz., "What is the best hand camera?"

ADDRESS WANTED.—EDWARDS & SON write: "Will you kindly give us the address of Mr. H. P. Robinson, who wrote article *Photography as a Business* some time ago?"—In reply: Mr. Robinson's address is Winwood, Tunbridge Wells.

PROCESS BLOCKS.—P. MILLEN. Yes, process blocks could be produced with much finer screens than those generally used commercially, but you must have in mind that the finer the screen the greater is the care required in printing; also that these fine screens necessitate a better quality of paper and ink than are usually employed for commercial work.

THE EXHIBITIONS.—CHALKLEY, GOULD, & Co. write: "Would you kindly inform us through the medium of your paper the latest date for sending in photographs to the Royal Photographic Society's Exhibition in Piccadilly, and also for the Salon Photographic Exhibition, and oblige."—In reply: Our correspondents had better consult the JOURNAL for June 5 and 12. Dates and full particulars are given there.

PHOTOGRAPHING IN GREENWICH PARK.—R. J. DUBBIN says: "Will you please inform me to whom I am to apply for permission to photograph in Greenwich Park, &c.? I know you have made this known through the JOURNAL several times, but I cannot remember it now. Thanking you in anticipation."—In reply: Permission may be obtained from the Secretary of H.M. Office of Works, 12, Whitehall-place. We do not undertake to reply through the post.

UNEQUAL TIME IN SHUTTER.—CYCLIST. There is a very simple explanation of the discrepancies in the exposures, although the shutter was set at the same speed for all. You mention that you travelled on your bicycle fourteen miles to take the pictures, consequently particles of grit from the dusty roads got into the working parts of the shutter, and thus had an influence on its normal speed. That must always be the case with shutters of the type mentioned, unless they are carefully protected from dust when touring.

STUDIO AND BUSINESS.—Twenty-seven to thirty feet long, by twelve or thirteen feet wide, will be good proportions. The amount of glass, top and sides, will very much depend upon the aspect and the form of studio settled upon. We can give no idea of the cost, as the price of material and labour vary in different localities. Get out a plan of the building desired, and then ask local builders to estimate for the work. Any light business you are familiar with will go with photography, such as carving and gilding, stationery and printing, &c., if you are proficient in them.

PATENT.—S. G. writes as follows: "I have recently applied for a patent for an invention I have made, and a provisional protection has been granted me by the Patent Office, and I am now making the article. A friend, who professes to know more than, I think, he does, says I am not entitled to call the thing 'patent,' and that I am rendering myself liable to a penalty. Kindly give me your opinion."—Your friend is quite right. You have no patent, and, by saying you have, you incur a penalty. You may use the terms, "Patent applied for," "Provisionally protected," &c., but not "Patent."

NON-DELIVERY OF GOODS.—H. HUGHES says: "Will you kindly advise me what to do in the following? On May 29 I ordered and paid for a camera and slides of Messrs. ——, who advertised in your JOURNAL of that week. They informed me the camera and slides would be sent on the following week. On June 12 and 17 I wrote again, asking them to refund cash or forward the goods. To neither of the letters did they condescend to reply. I informed the Superintendent of Police in this district, and he has not heard anything. I see they are still in the land of the living, as they advertise elsewhere this week. How can I get camera and slides or my money back?"—In reply: A County Court summons would, no doubt, be your best course. We do not know the firm.

DUSTING-ON PROCESS.—T. HOMEWARD says: "I have been trying the powder process for the first time, and cannot get on at all with it. I have tried two of the formulæ given in the ALMANAC, but the result is the same with both, the powder will not take. My object is to make reversed negatives."—The failure may be due to two causes. First, over-exposure. If the print be over-exposed, the powder will not adhere. Second, the film too dry. Moisture plays an important part in the process, and the atmosphere has been very dry of late. Probably, supposing the plates were not over-exposed, if they had been developed in a damper atmosphere, the results would have been different. There are other causes of failure, but we have indicated the two chief ones in the direction mentioned.

PLATINOTYPE TROUBLES.—NEDDIG says: "If you could help me over the difficulty I am about to bring to your notice, you would be doing me a great favour. The print enclosed is a platinum, developed in the ordinary way with oxalate, and has had three acid baths, also sixteen changes in washing. The rubber backing was dried before using, and the frame kept indoors. You will notice the wretched yellow tone which appears, more or less, in every print we do. If you could give me any hints as to how the splendid blue-black tone is got by some people it would solve the mystery. I may add that I am a professional, and, as you may guess, my employer is far from satisfied with the platinums; so you will understand how any hints would help me. I have also tried Dr. Jacoby's platinum paper, with the same result."—So far as we can judge from the print sent, supposing that the manipulations were carried out in the usual way, moisture is the source of the trouble at some stage or other. Possibly the paper was not in good condition when received. Try another brand, or communicate with the makers of that in use.

DISCOLOURED PRINT.—J. B. C. says: "The enclosed print, which I should be obliged if you would return, is a curiosity, the mystery of which I should much like solved. It is on Eastman's permanent bromide, developed in metol and carbonate of soda, thoroughly washed, fixed in pure (recrystallised) hypo, about one pound in one hundred ounces, for twelve minutes, then washed one and a half hour in Wood's washer. I am not certain—I thought not—but I may have toned it about three minutes in uranium and prussiate of potass solution, and then washed fifteen minutes. I believe it was not toned, but, as I did several in the batch, can't be quite certain. I made the print last night, and this morning it was white; at one o'clock, as it leaves here, blue. The marks in the corners come from my shutting it in a book without noticing that they were still wet. It was exposed to the light all the morning."—In reply: We cannot tell the exact cause of the blue colouration, but in all probability it is due to the access of iron to the potassium ferridcyanide of the toning solution, which would result in the formation of a blue deposit, and the consequent discolouration of your print. Still, this is only a surmise on our part.

OVER-EXPOSURE AND CHLORIDE RESTRAINERS.—SHARP FOCUS says: "In your No. 1881, of Friday, May 22, I read an article on the above, by Mr. Matthew Wilson. Having some negatives which I know to have been considerably over-exposed, I applied to my dealer for the standard ferric-chloride solution mentioned by Mr. Wilson, and at the same time gave the article to him (dealer) to read. He tells me he would not advise me to try this method, as he is sure I have read the article wrongly, and that Mr. Wilson means the over-exposed plate to be developed first, then soaked in ferric chloride, and, lastly, redeveloped. I read the article to soak for five minutes in ferric chloride first, and then to develop. I should feel obliged if you would direct me on this point, as also how to make up the ferric chloride. I have also seen some other methods described, which, however, I forget at present, and in any case place more reliance on your paper than on others. It appears to me that such articles as Mr. Wilson's are of far greater importance and worth than all the trash that is published by 'Fuzzy Jones' to prove out-of-focus photographs better and more artistic than paintings. I enclose stamped addressed envelope for reply through post."—In reply: We do not undertake to reply through the post. You read the article aright. The author says he first soaks the plate in ferric chloride, and then develops. As to the method of preparing the standard ferric-chloride solution, if our correspondent will turn to the JOURNAL of April 10, he will find that the author of the article gives the necessary particulars.

*** Many communications stand over on account of pressure of Convention matter.

NOTICE.

With the JOURNAL *of this week we issue a half-tone illustration, by the Strand Engraving Company, representing some of the members of the Eleventh Annual Photographic Convention of the United Kingdom, assembled at Leeds on Wednesday, July* 15, 1896. *Mr. D. McIver, of Leeds, took the negative. A key, with the names of members, is also given; and, although it is unavoidably incomplete, we tender our thanks to the several gentlemen who assisted us to identify many of the members. We shall be glad to have the names, for publication next week, of those members who are not named in the key.*

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1891. Vol. XLIII.—JULY 31, 1896.

Contents.

EX CATHEDRÂ.

Our contemporary and neighbour, the *Echo*, draws attention to the congested state of the market traffic in and about Covent Garden on certain mornings of the week, and hints at the terrible condition of things that would ensue on the outbreak of a fire in the locality when it is blocked by waggons, carts, horses, produce, &c. It asks for the opinions of, among others, the editors of papers published in the immediate district. We have no hesitation in observing that Covent Garden Market is a nuisance to the locality. In time to come we, or our descendants, will be smiling at the fact that in this year of grace, 1896, the greatest city in the world was content to put up with the numerous inconveniences of a small and shabby vegetable, fruit, and flower market, such as would disgrace a town not a tenth of the size of London. Covent Garden and its approaches on a market morning cry aloud for the photographer; for, without the irrefragable records of the lens and the dry plate, we fear that not only our descendants, but many people still living at home and abroad, would find it hard to believe that such a deplorable place as "Mud-salad Market" ever had an existence in fact.

The echoes of the Leeds Convention have hardly died away before we find ourselves instinctively looking ahead to the Great Yarmouth meeting of 1897. We are glad to observe that thus early the press of the interesting seaside town for which Nelson had so much affection is well disposed towards the Convention, and evinces every anxiety to make the visit a success. The *Yarmouth Mercury* takes a very practical view of the advantages likely to accrue to the town from the Convention meeting. It remarks: "The visit will not only be the means of bringing many strangers into our midst, but will also prove a huge advertisement, as photographs of the scenery of the locality will find their way into every part of the kingdom. As there are many thousands of the inhabitants of the British Isles who do not know of the charms of our town and broadland, it must inevitably follow that the subsequent exhibition of the views taken hereabouts will result in our reaping a rich harvest. Mr. Harvey-George informs me that some 500 members are likely to come here next July, and it is to be hoped that the Mayor and Corporation will render the Camera Club every possible assistance in entertaining the visitors, as the Mayors of other towns have done." The kindly spirit in which the Convention is thus regarded will assuredly not be lost on its many members.

* * *

Shakespeare's Town and Times is the title of a book by Mr. and Mrs. Snowden Ward that is to be published forthwith, and to which we shall shortly have an opportunity of further referring. From the synopsis of the contents we anticipate a readable and painstaking life of the "bard of all time." There are over 120 illustrations in the book, most of which are in half-tone from negatives made by Mrs. Ward. The subject and the admirable manner in which it appears to be treated should ensure the work wide appreciation and success. The world cannot tire of Shakespeare, and it is always ready to shower thanks on those who write of him, illustrate him, or act him earnestly and well.

* * *

The brief report of the National Association of Professional Photographers' meeting, held at Leeds in the Convention week, that appeared in our last number, is pleasant but disappointing reading. Of business tending to advance the interests of the photographic profession, or even of individual members thereof, the Association appears to have done none at all. It is, without doubt, a thing laudable enough in itself to bring together

once or twice a year a number of professional men for purposes of social intercourse, but, unless a distinct community of interest also prevails, experience shows that mere festivity and enjoyment are powerless to prolong the existence of peripatetic organizations such as the N.A.P.P. May we, as sincere and well-wishing friends of the photographic profession, express the hope that an early opportunity will arise for proving to the world that the National Association of Professional Photographers is not doomed to succumb to inanition?

* * *

An old friend and correspondent of the Journal, Mr. H. H. Cunningham, J.P., sends us this week a letter from Georgetown, British Guiana, in which the disadvantages that wait on photography in a hot, humid climate are realistically described. What does the stay-at-home photographer think of the phenomenon of plates being attacked by bacterial growths in a fortnight, or of the difficulties that also necessarily beset printing? The production of photographs under such conditions is a task that would delight a Tapley. Mr. Perkins's paper on *Photography in British Guiana*, which, by the kindness of the author and Mr. Cunningham, we also print, is a record of photographic work achieved in disadvantageous circumstances that forms instructive reading. We wish our friends of the British Guiana Graphic Club success in their pursuit of photography.

* * *

The following interesting announcement appears in a Newquay publication:—"After seven years of patient investigation, our townsman, Mr. Wallace Bennetto, Photographer of Newquay, has attained what at one time appeared to be an unrealisable dream, viz., photography in colours of nature, by *purely* photographic means. The results by this process are, beyond imagination, beautiful, being, in fact, what a true photograph should be, an exact representation of the subject. When the surroundings of Newquay are considered, it will readily be believed that photographs of the cliffs against the electric blue of the sea, varied by sea pinks in full bloom, are something quite in contrast to anything that has hitherto been accomplished.

* * *

"Several leading scientists and distinguished persons have seen the results, and have declared them marvellous. Those we have seen have left us with the same feeling, and we are glad now to publicly, as we have long ago privately, congratulate Mr. Bennetto on having discovered the long-sought-for Philosopher's Stone of photography. Mr. Bennetto intends to give an Exhibition at Newquay before the season is over. Already pictures of Newquay beaches and cliffs, sea and sky studies, sunrises and sunsets, flower pictures, and figures have been taken, and will appear with others in the Exhibition. The Exhibition will really be one of the greatest events in photography since its discovery, and this development by Mr. Bennetto will be regarded by the future scientific historian as of the greatest importance. We hope to be in a position to give further information soon; meanwhile we congratulate our town and ourselves on the discoverer being a Newquayite."

* * *

We endorse the aspirations contained in the concluding sentences of the above extract, but are surprised to learn, from a correspondent, that Mr. Bennetto declines to show the results to a photographer. We should have thought he would have sought the earliest opportunity to have had his discovery professionally verified.

PLATINOTYPE AND PLATINOTYPE PRINTING.

The gradual spread of platinotype work is made evident by the increasing number of queries on the subject we receive, as shown by our Answers to Correspondents. Experts in the process, and it is a simple one, can scarcely understand what there is to inquire about, but the query of a professional printer, as seen in our issue for last week, is a fair sample of the difficulties some beginners experience. Again, we were quite recently shown a letter received by a well-known contributor to these pages from a photographer with a large studio and good business, asking if he would object to do some platinotype prints, the writer having an order for some and not being able to get good results. Taking all these facts into consideration, it is evident a few practical remarks on the subject will be useful to many of our readers.

There is, however, at the outset, one piece of advice to give, which we offer in the confident assurance that, if attended to, it will solve the difficulties of nearly every worker. It is brief and to the point: "Carefully read the manufacturer's paper of instructions, and attend to them." It is quite easy to do this; yet how few there are who have adopted the advice!

The most important consideration in connexion with this class of prints is their permanency or otherwise. As to the prints being permanent, in the true sense of the word, there can be no possible doubt; but there is one little difficulty that arises. We have been told many such pictures have been known to fade. This we have always denied, the fact being that no fading can take place; but, at the same time, a large number of the platinotype prints sent out by workers of the highest skill do turn yellow or various shades of light brown in the whites. Nothing fades, but the whites discolour. Can this be prevented? Save by a complete sealing from the air, we have grave doubts. Most of the platinotypes we have seen after the lapse of a few years undoubtedly "go" in the whites; but, if there is no absolute prevention, it is true that, by carefully attending to instructions, this discolouration will be reduced to a minimum. Never less than three (and four would be still better) acid baths must be used, and, further, the prints must be continually separated while in the baths, or a larger proportion of iron will be left behind. It is the greatest mistake in the world to hurry this part of the process. We have before us as we write an exceedingly good portrait in platinotype, done by a well-known lady photographer, whose prices do not suggest any need to cheapen the cost of production, yet, though only a comparatively recent picture, it has gone a sickly, dirty yellow all over, showing this, of course, only in the whites and lighter tones. We therefore again say, Do not economise in the use of acid baths, and, above all, do not try to do cheaper work by using commercial hydrochloric acid, the yellow colour of which is mainly attributable to iron; that is the very body which we desire to keep out, or to eliminate when present; for it has been conclusively demonstrated that it is to the presence of iron imprisoned within the fibres of the paper that the degradation of the whites is attributable.

The next point that troubles so many is the want of crispness and brilliancy in the prints. But, in the first place, it must be remembered that a print, however brilliant, done on a dead surface, cannot compete for richness and range of tones with one done on a glossy surface. Leaving that point aside, however, it is certain that some workers only get the poorest, greyest, flattest of effects, whatever negative they print from and whatever the brand of paper they employ. But the main cause of this is simply the want of attention to instructions.

Those unaccustomed to chemical experiments cannot understand the readiness with which anhydrous substances can attract water from the atmosphere, but we wish to say in the most emphatic manner that a piece of unprinted platinotype paper left lying about for a few minutes is rendered worthless for producing perfect prints. Anything which leads to the possibility of moisture being absorbed leads at the same time to flat prints. Even when the paper is removed from the frame the same care must be taken. It is absolutely necessary to keep them in a box suitably prepared for retaining a dry atmosphere. If the prints are merely put in a drawer, or placed in any ordinary receptacle, poor prints will result. They must be placed in a box supplied with a desiccating material. Asbestos, impregnated with chloride of calcium, is usually employed. Yet, again, it must be remembered this drying agent does not last for ever; it soon gets wet, and is then useless till it has been strongly heated to drive off the moisture it has absorbed. For the same reason care must be taken not to leave the lid off either the store tin or the tin in which prints are kept. Every time the lid is removed, damp air enters, and has to be desiccated by the action of the absorbent. We are convinced that the bulk of the complaints arise from this source of evil alone. Paper will keep good for months if the original package be not opened.

Another point that has been objected to is that the tone cannot be varied to the subject, like albumenised paper; but surely this is no disadvantage if the defect exists; no one complains of the want of variety in the colour of engravings. But, as a matter of fact, there is considerable variety of tone possible. First, there is the sepia modification; and, next, a great variety of shades of black to brown by varying the temperature of the solution and the length of time of keeping the unused paper.

Others, again, have it that it it necessary to use a special class of negative to get good results; but the paper is so much improved nowadays that it must be a very poor, thin negative from which a good print cannot be got. Further, almost every degree of hardness or softness may be obtained by using new or old paper.

A rusty colour in the shadows is often complained of. Here, too, it must be remembered that bronziness in the shadows of an albumenised paper print cannot always be avoided, and in platinotype this rustiness is comparable to bronzed shadows. It can, however, often be avoided by using weaker developing solution. It is possible that occasionally the makers send out papers defective in this respect, but none but experienced workers are competent to say that this rustiness comes from over-strong developer, and that rustiness comes from defective paper.

We have briefly touched upon the points most likely to arise in the practice of beginners, and, in conclusion, will repeat our advice, that most troubles will disappear if the makers' instructions are learnt and followed.

PRINTING DIFFICULTIES IN HOT WEATHER.

That we are now passing through one of the most trying periods of the year scarcely any of our readers will require reminding; but, though the difficulties surrounding the use of our plates of to-day during hot weather are far less than they were ten years ago, the same cannot be said of our printing papers. Now is the season when the alum bath becomes an absolute necessity with gelatine papers, and even with collodio-chloride it is a great aid to success. With the former, although the prints, with care, may pass safely through the ordeal of washing without damage, it is practically impossible to mount them. We have heard many complaints lately in this direction, and only a few weeks ago we experienced the difficulty ourselves with some gelatino-chloride prints that had been dried after washing, but without using the alum bath. They were rewetted previous to mounting, but the gelatine surface proved more adhesive than the mountant, and, on rubbing down, they became firmly attached to the paper used, and, after ineffectually trying to save the first two or three, we were compelled to alum the rest.

During the hot and "thundery" period of last year, about this time, we heard a good deal about the effect of heat and thunder on gelatine films, but the most remarkable instance we have yet heard of the narrowness of the line that divides us from the borderland of danger with gelatine papers has just reached us from an amateur correspondent. It appears he had just finished toning and fixing a number of gelatine prints, and, though the weather was by no means sultry, it was close and "thundery," a storm actually occurring a few hours later. The prints had appeared more than usually tender, and had required careful handling, but had shown no signs of actual softening. The dish containing them had been left for a few minutes on the kitchen sink, when, on going to change the water, the colouring matter was seen to be oozing out from between the prints and the dish in precisely the same manner our correspondent describes it—as from a piece of carbon tissue before stripping for development. On attempting to lift the prints, those in contact with the bottom of the dish were found to have melted and become attached firmly to it, while the upper layers were perfectly intact. A subsequent inquiry showed that, during his absence, the domestic had emptied a saucepan of hot water into the sink, and this, flowing round the porcelain dish, had warmed it sufficiently to upset the "tottering state of equilibrium" of the gelatine and produce the result stated.

Many workers with gelatine papers object to the use of alum, on account of the difficulty of ensuring its complete removal after it has done its duty. Alum, we know, has been recommended as an eliminator of hypo, and in that capacity we know many have used it to their cost, and have come to regard it with no friendly feelings. The opinion so frequently expressed in these columns on the subject of hypo eliminators is well known, and we are inclined to agree with a statement we heard made a few days ago, that, of the two, alum is a more dangerous enemy to our prints than hypo. If carelessly used or imperfectly removed, it is undoubtedly so, and we can safely say, from our own experience, that we have had more cases of unstable prints from amongst those that have been alumed after fixing than from those not alumed. Very probably, if the alum were applied before fixing, it would not prove so dangerous, because, knowing the necessity for its removal before passing the prints into the hypo, greater care would be taken in washing.

We are inclined to believe that a far safer application will be found in chrome alum, especially if it be first purified by Professor W. K. Burton's method of washing the powdered crystals with spirit. We have used it in place of ordinary alum, in solution of about four or five grains to the ounce, and, judging by the comparative effect produced by prolonged immersion, we should say it is far safer than that salt. If a print be cut into three portions and immersed in solutions of ordinary potash alum, chrome alum, and hypo, the first will be bleached out or turned yellow in two or three hours at the

outside, that in the hypo undergoes a very gradual reduction in depth, but no serious discolouration, for perhaps twenty-four hours, while the chrome alum seems to make very little difference.

It has been recently recommended to alum collodio-chloride prints, in order to harden the gelatine under surface, and some operators perform this function before toning; but it cannot be too strongly borne in mind that, unless very completely removed before toning, the alum will cause great trouble. This has been pointed out in connexion with gelatine prints, with which it has been recommended in order to counteract the softening effect of sulphocyanide. With collodion, owing to the nature of the film, it is not supposed to require so much washing to remove it. This is perhaps true so far as the collodion itself is concerned, but there is the gelatine film underneath to be considered also, for which reason we advise that at least as perfect washing be given, or else the alum left until after toning at least.

Shortening the Exposure in Röntgen Work.—In reference to the suggestion of Mr. Porter recently described by us, Mr. Alexander Thurburn writes to *Nature*, giving details of a very easy method of applying it. He says: "Many tubes for Röntgen-ray researches have the edge of the cathode mirror opposite the short neck, and in such cases the expedient, described by Mr. Porter in your issue of the 18th ult., can be very easily carried out by fitting an indiarubber ring on this neck, winding two coils of copper wire round it, and leaving two or three inches free at one end, which is then bent so as to bring the point sufficiently near to the cathode loop." This seems a very easily arranged application, which any of our readers would have no difficulty in bringing to a practical test.

The Balloon Polar Expedition.—The steam ship *Lofoten*, which left Spitzbergen on the 18th inst., reports that Herr Andrée would commence filling the balloon on that day, and, if the meteorologic conditions were favourable, would make the ascent on Monday last, the 27th. This venture has been much commented upon ever since it was first proposed, and the safety of the intrepid explorer and what he will accomplish engages the minds of many at the present time. It requires a considerable degree of pluck for an arctic expedition, even with the most complete equipment, but with such a frail bark, and one of such an uncertain destination as a balloon, much more. Every one wishes Herr Andrée all the success his daring enterprise deserves, and a safe return.

Photographic Evidence.—On several occasions we have alluded to the fact that the ends of justice might frequently be furthered if photography were used more in evidence than it usually is. For example, in the case of railway accidents, photographs, if taken immediately after the occurrence, and before anything is disturbed, would sometimes help materially to elucidate the cause. So in the case of murders, where there is often a great discrepancy in the evidence of witnesses as to the state and position in which the victim was when first discovered, owing to the natural state of excitement at the time, photographs, if forthcoming, would often be more decisive. We notice in a report of the inquest on the body of the unfortunate girl who was recently murdered at Hemel Hempstead that the doctor who was called in his evidence said that, before allowing the body to be disturbed, he took five photographs of it. Those photographs, whether they help in furthering the ends of justice or not, are better evidence as to the position and surroundings than will be any verbal testimony that may be brought forward.

The X Rays in Divorce.—By the New Photography is generally understood by the lay public, and even photographers, photographs produced by the Röntgen rays. In connexion with this subject, a correspondent sends us a cutting from a daily paper—an advertisement of one of those inquiry agencies that engage to find out where private people go, what they do in their late hours, what company they keep, &c. We give the cutting as it appears *verbatim*, omitting, of course, the name and address, as we shall not give this, to us, latest expert in the New Photography a free advertisement: "The New Photography.—Owing to the success ———— has personally achieved with the New Photography, he is prepared to introduce same in divorce matters free of charge." To us it would be exceedingly interesting to learn how Röntgen's discovery is, or can be, utilised in divorce matters, even if a substantial charge were made, instead of its being free. At present, we must confess it is "beyond our ken," and probably is beyond that of Professor Röntgen himself. This is the only reply we can give to our correspondent.

Röntgen Rays.—A few weeks back we mentioned that a Berlin physician had found that the intestines could be photographed by the X rays provided they contained solutions of metallic salts. Now, according to the Berlin correspondent of the *Standard*, a German army doctor has found that chlorine, bromine, and iodine in a pure state are not easily penetrated by the Röntgen rays, but that this fact is not a consequence of the grouping of the atoms in the molecule, but depends upon the atoms of the haloids. From that he concludes that all chemical combinations of the halogens are impenetrable by the X rays in proportion to their halogenic percentage. This doctor—Dr. Scharwald—has also found that the shadows of the soft parts of the body are partly produced by the iron contained in hæmoglobin and in the alkaline metals, and especially by the chlorine the soft parts contain, and that muriatic acid, chloroform, liquid chloride of carbon, and especially liquid bromoform, all free from water, are almost impenetrable to the Röntgen rays, and they therefore act as a filter for them. The four most important elements—carbon, hydrogen, oxygen, and nitrogen—it is also said are almost absolutely penetrable by the rays. If this be the case, there seems to be a further important use for Röntgen's discovery.

A Cause of Unsteadiness in the Use of Delicate Recording Instruments.—Every one familiar with microscopic work, visual or photographic, is aware of the almost complete improbability of avoiding tremors at all times under the usual conditions. Professor H. Turner at Oxford has been making a series of experiments which have a practical bearing upon the point, working upon old data which suggested the possibility of the weight of a shower of rain actually causing a distortion of the earth's surface, as he could not call down with success a shower of rain whenever he wanted to test the matter, he utilised the services of a body of sixty-seven men, whom he marched and countermarched in compact or in loose order, and found that no effect was produced until the walls of the observatory were reached. Hence he concluded that, with regard to displacement from the vertical of any apparatus, there was practically nothing to be apprehended from such an event as a heavy fall of rain. It was yet evident that external agencies are quite capable of effecting the indications of delicate instruments. For example, "small local earthquakes" were supposed to be acting causes in such cases.

Departure of the Eclipse Expedition.—This expedition is now on its way, and is timed to reach Vadso on Monday next, so as to allow sufficient time to make the necessary preparations for the work to be done. This expedition is unique, inasmuch as it is a scientific one and a pleasure trip combined. It has been arranged and carried out by the Messrs. Gaze, who have chartered the *Norse King* for the purpose—a large vessel, formerly one of the P. and O. liners. It has about a couple of hundred berths, lighted throughout by electric light, and magnificently fitted; indeed, it may be considered a first-class floating hotel. Large as is this vessel, it was found necessary to supplement it by another, to accommodate some sixty more passengers, for whom there was not room aboard the *Norse King*. Few scientific expeditions have been made under such

uxurious conditions as this. Often they have been made under just the reverse state of things, and the members of them have had to put up with many discomforts, not to say "rough it." Amongst the company are many ladies, doctors, professors, colonels, a bishop, &c. It is to be hoped that this array of talent and learning, under such auspicious conditions, both as regards time of day and season of the year, will materially add to our knowledge. The duration of the eclipse is about a minute and three-quarters at Vadso.

A Cheap Grating for Astro-photographic Special Work.—The very great expense attendant upon the use of a diffraction grating is a bar to its employment by many; but a recent invention of Messrs. Hall & Wadsworth, described in the June number of the *Astro-physical Journal*, will enable the desired work to be done at an immense reduction in cost of apparatus. Some idea of the saving possible will be obtained when it is stated that the new grating, if applied to the Lick telescope, for example, would only cost the one two-hundredth part of what would be required for the ordinary kind. The experiments were made with a twelve-inch lens working at an aperture of *f*·18. Two screws twenty-seven cm. long, and with sixty-three threads to the centimetre, were cut in two along their axes, and the half screws mounted parallel to each other on opposite sides of a rectangular frame. Copper wire was thrown across the successive threads of the half-screws, and soldered to them so as to form a grating. When applied to the telescope, photographic spectra of both the first and the second order could be obtained, and cases are quoted showing the agreement of the adduced wave-length with Rowland's values. The exposure to wind was found disadvantageous, but it is proposed to avoid this by soldering light rods across the wires parallel to the half-screws.

Stability of Aluminium.—The uses to which this metal is being put are so numerous, and in photography it is so very useful, that many investigations have been made as to its power to withstand not only atmospheric influence, but also the corrosive action of many substances with which it is likely to be brought into contact. The cause of the dull grey tarnish so familiar upon unlacquered aluminium has been attributed to the presence of small quantities of sodium taken up in its manufacture, and means have been devised for preventing its presence. The *Journal of the Franklin Institute* contains a paper on this subject by Mr. J. W. Richards, who has been investigating the action of corrosive liquids upon the metal when alloyed with various other metals. The bearing of his experiments is to the effect that pure aluminium is more resistant to alkalies than any alloy, as it is also to nitric acid and common table salt solutions. If, however, free hydrochloric acid is contained in a liquid for which aluminium vessels are employed, Mr. Richards finds that an alloy containing two per cent. of titanium is of advantage.

It is worthy of note in this connexion that mercurial salts, so often found in the photographic laboratory, are, according to Mr. Percy A. E. Richards, F.I.C., writing in the *Chemical News*, decidedly injurious. He finds that nearly all mercurial salts have an action of a continuing character. "It seeems to me," he writes, "that this result is brought about by the mercury first forming an amalgam with the aluminium, and this, reacting at once on the moisture present in the air or on the surface of the metal, forms alumina, at the same time liberating the mercury, which once more forms amalgam. . . . In short, these results show that the greatest care should be taken to prevent any apparatus, &c., of aluminium being brought into contact with mercury in any shape or form."

FOREIGN NEWS AND NOTES.

Development of Chloride Prints.—Ed. Liesegang, in the *Photographisches Archiv*, expresses the opinion that the development of printing-out papers will be more generally adopted, and may supplant other processes. Such prints are also superior to those produced on the usual papers for development only. The developer should not be alkaline, or at most only slightly so, otherwise fog ensues. Wilson's method he rejects as being difficult to work. Ferrous oxalate and amidol also are quite unsuitable, as they produce a general blackening of the image. Hydroquinone and gallic acid are practically the only two useful developers. Others, like pyrogallol, brenzcatechin, and para-amido-phenol, produce unpleasant tones. Hydroquinone, with acetate of soda and citric acid, yields prints that, after fixing, have the appearance of ordinary prints, viz., a warm reddish-yellow. Gallic acid, with addition of acetate of soda, also produces warm tones if printing is somewhat full and development stopped at an early stage; but the tones are not as pure as with hydroquinone. With short exposures the tone assumes a greenish colour. The methods of development may be divided into two classes: the first, in which a colour is given to the picture that does not require modification by toning with gold. This can be done with gallic acid, and red-brown, olive, or greenish-black prints may be obtained. The second method requires after-toning in a combined bath. A little reflection will show that hydroquinone is the most suitable for this, because the toning depends upon the presence of a red silver deposit, which is modified by the blueness of the gold. The photographic tone is due to the red of the silver showing through the thin blue deposit of gold. Black bromide prints will receive a deposit of gold, but are not toned because the colour cannot be modified by the gold deposited. Some time ago the writer recommended tannin as a developer. It yields a red tone, but is valueless in practice. The colour is not as pure as with hydroquinone; the back of the print is liable to discolouration, and it spoils the combined bath.

Copying Frame for Photographs on Wood.—In *Die Photographie* we read that a new frame has been patented by K. Schlatter, of Stuttgart. It has the appearance of an ordinary pressure frame, but without the back and springs. The negative is held in position by means of thin, broad steel plates, fitted with screws for adjustment to any of the usual (Continental) sizes, and the plate cannot be shifted. The block of wood is brought into position by means of fine-threaded screws, of which there are two on each side of the frame. The pressure is secured by means of small screws, which are more suitable than wedges, on account of greater uniformity. The block can be examined as often as necessary without fear of displacement.

Warnerke's Sensitometer.—A source of error in the use of this instrument, that has hitherto been unnoticed, forms the subject of a short article from the pen of Dr. G. Eberhard, in the *Photographische Correspondenz* The sensitometer is constructed with a shutter between the scale and the phosphorescent tablet. The latter is hinged, and is turned over, like a door, on to the scale for exposure. Thinking the shutter might be an unsafe protector of the plate, whilst burning magnesium in front of the phosphorescent tablet, a trial was made by inserting a plate in the frame and burning three centimetres of magnesium ribbon at five centimetres' distance from the closed shutter. To the writer's astonishment, about eight numbers of the sensitometer could be easily read on the plate. As a distance of five centimetres is usual in burning magnesium ribbon in front of the tablet, the writer recommends the substitution of a metal shutter for that of wood supplied with the instrument.

Toning Lantern Slides.—In the same periodical, Th. J. Placzek, of Vinna, writes in reference to the toning of collodion transparencies. If pyrogallic acid be used, instead of iron, for development, a pleasing blue-black deposit results, that can be easily toned with neutral chloride of gold, chloride of palladium, &c.; but the large addition of glacial acetic acid to the developer makes double the exposure necessary as compared with iron development. In consequence of this, attempts have been made to tone the greyish-black image of iron-developed positives, and the following bath has been found very useful:—

Solution of potassium chloro-platinite (1:50)	4 c.c.
Nitric acid	12 drops.
Solution of chloride of gold (1:50)	3 c.c.
Distilled water	550 to 600 „

The plates, after fixation with hyposulphite of soda, or preferably cyanide of potassium, are well washed, and, whilst still wet, placed in the toning bath for one to two minutes. They acquire a blue-violet tone, which is found very suitable for lantern slides or stereoscopic transparencies. Dry-collodion plates may also be toned in this bath, but the process is much slower, owing to the horny character of the collodion film, which resists the penetration of the solution. A bath of potassium chloro-platinite (1 : 1400), slightly acidified with hydrochloric acid, gives a blacker tone. A solution of—

Water	500 parts,
Sulphocyanide of ammonium	20 „
Hyposulphite of soda	½ part,

added in equal quantity to the following:—

Water	500 parts,
Chloride of gold solution (1 : 50)	30 to 40 „

gives grey-blue tones. Platinum and gold toning is very successful with these baths.

Phosphorescence in Development.—A. Helheim draws attention to this subject in the *Photographisches Archiv.* After reciting the experiments of Dr. Neuhauss in 1892, Dr. Precht in 1895, and those of Lenard and Wolff in 1888, he writes that he has had similar experience in studying the action of formaldehyde as a constituent of the developer. He made up a developer of—

Water	30 grammes.
Pyrogallic acid	1 gramme.
Carbonate of soda	1½ grammes.
Formaldehyde (40 per cent.)	2 „

The negative was over-exposed and fogged. After laying aside a few minutes, the plate was seen to glimmer, first at the edges and then towards the centre. The light was bluish-white, and observable even in presence of the dark-room lamp. The phosphorescence appeared as soon as all moisture was absorbed from the surface, and lasted several minutes. Thinking the absorption an important factor, as the phosphorescence was imperceptible whilst the plate was in the dish, the writer tried the effect of another absorber of water, and added 30 c. c. of alcohol to the developer. A very intense phosphorescence was at once visible. As it passed away, it could be revived by shaking the bottle. The addition of alcohol, of course, precipitated the carbonate of soda, and produced similar conditions to those in the experiments of Lenard and Wolff, who poured pyrogallic acid developer into an equal quantity of saturated solution of alum.

The Roller-blind Shutter.—Dr. R. Krügener, in the *Photographische Mittheilungen*, compares this shutter, used immediately in front of the plate, with one he has constructed of similar pattern for use in front of the lens. He maintains that a slit passing in front of the lens can be quite as effective for exposure as a slit passing immediately in front of the plate. Light, passing through a slit in a shutter on the front of the lens, will fall upon the plate in band form. Take a blind 40 mm. long with a slit 3 mm. wide. This gives an aperture of 1·2 sq. c. The lens, a collinioscope, with aperture of 35 mm. and largest effective stop of 30 mm., covers the plate 13 × 18 c. sharp to the edges. The slit exposes on the plate a band 30 mm. wide, or about ⅛ of the length. But, as the blind aperture is 1·2 sq. c. and the aperture of the stop is about 7 sq. c., the illumination is only about ⅙, as compared without the shutter. But, as the light passing through the slit covers only ⅛ of the plate, it is six times more intense, for with full aperture the light is distributed over the entire plate. It therefore follows that, in using the slit in front of the plate, even with full aperture, no more light passes the blind than if the shutter is placed in front of the lens. We have now only to deal with the breadth of the band of light. With the same speed for both shutters the band of light, 30 mm. wide, with shutter in front of lens, must travel 4½ times quicker across the plate, than with the blind next the plate. The first must traverse 40 mm., and the second 180 mm. Theoretically, a slit of the breadth, $\frac{30}{4·5} = 6·6$ should suffice, if next the plate, and in practice, as shown by comparative experiments, the writer finds such a slit gives the same results as a slit of 3 mm. in front of the lens. A shutter fitted to the front of the lens may be turned to any angle, according to the subject, and its smaller size is a great advantage.

A German Photographic Convention.—The *Deutsche Photographen Zeitung* announces the twenty-fifth Convention of German Photographers at Trèves on August 25 to August 29. This is a professional gathering, and promises to be very successful. There will be an exhibition of photographs, apparatus, and objects of historical interest. Excursions and papers on photographic subjects also form part of the programme. The German Photographers' Association have organized this gathering, and their balance-sheet for the year ending December 31 last shows an income of about 530*l.* There is a balance in favour of the Association of about 170*l.*, subject to some outstanding liabilities. We wish our German friends every success, and we hope their Convention will be a most enjoyable one.

CELLULOSE AND ITS DERIVATIVES.

[Royal Photographic Society.]

WHAT has cellulose to do with photography? is a question which may have occurred to many of our present audience, and may express a certain curiosity which accounts for their presence. We, on our part, do not expect to gratify any anticipations which proceed from the "Athenian" desire to hear some new thing. In the first place, cellulose is an extremely common substance, and while it is, so to speak, the theatre of many of the most striking dramas of the molecular world, it would be itself popularly described as an extremely uninteresting substance. It is true it discharges a number of important functions in the natural world, and then employs a stupendous amount of capital and labour in fitting it for further uses in the human sphere. But the same might be said, for instance, of water; and it is not to be expected that a substance, colourless, inert, and devoid of positive characteristics, and, above all, of the commonest, should be able, *per se*, to excite the imagination. In the domain of science, on the other hand, nothing is "common;" and, if a substance plays a large part in the natural order, it is entitled to the more consideration. In endeavouring to treat scientific subjects from the point of view of general interest, these aspects always conflict, and the present is not likely to prove an exception. If, therefore, we venture on an all-round treatment of the subject matter "in the hope that by any means we might save some" who, as yet, are in darkest ignorance of the position and function of this remarkable substance, cellulose, we are sure to offend fellow-specialists who are well acquainted with the essential outlines of the subject, but who may expect disclosures of new matter containing suggestions of theoretical or technical progress. *Que faire?*

Perhaps, if we address ourselves to the consideration of the uses of cellulose, actual and possible, in photography, we may succeed in getting somewhere near that highest level to which the lecturer can aspire, that is, to offend the least number.

Photographic processes depend essentially upon the two factors, the photo-sensitive substance and the medium through which it is distributed. This holds for photographic action in its widest sense, which is, indeed, of the widest, for it includes the whole arena of light actions.

What radiant energy accomplishes in the plant world we know as an aggregate: but the mechanism of its actions is as yet largely unknown. But here also, as in the photographic plate, we have the same essential factors, the photo-sensitive substance and the medium through which it is distributed.

In photo-sensitive substances we have the common property of absorbing light energy. The energy appears to undergo that kind of "appreciation" by which it becomes chemical or atomic. We are accustomed to changes of terms, or transformations in radiant energy. A familiar example is afforded by the "incandescent" gas burner: the hood or mantle of the special oxides of which it consists has the effect of changing the character of certain constituents of the total radiation of the flame, raising or lowering them to the condition associated with maximum luminosity. Another example, but of a different order, is afforded by the phenomena of electrolysis. The electric current is passed between two conductors through a fused metallic salt or its aqueous solution. The two constituents of the salt, metal and acid, are separated and appear each at its respective pole or conductor. This may be regarded in general terms as a com-

munication of energy to a compound body, and the appreciation of the energy lands the constituents of the compound into the emancipated condition of elementary or dissociated molecules.

So much briefly and superficially concerning the main function of the photo-sensitive substance.

And what of the medium? The media actually used in practical photography are not many. They have one feature in common, they belong to the group of colloids. The term applies to a diversified group of compounds containing representatives of all the more prominent chemical types: bases, acids, salts, alcohols, ethers, &c.

It distinguishes a common property of such compounds in solution, viz., that of forming, when dissolved, gelatinous or viscous liquids, as opposed to the limpid or mobile solutions of the compounds known as crystalloids. The group of phenomena summed up in these two antithetical terms were exhaustively investigated in certain directions by Graham, many years ago. But in recent years they have been more profoundly studied, and have in fact become one of the most prominent arenas of pioneer work in molecular physics. It is, of course, in the order of things that the problems of physical science should become more and more refined. The chemistry of a generation ago revelled in discoveries which were striking enough to excite the crudest intellects. Thus the enrichment of the world by the introduction of the coal-tar colours and the colossal industry which has been built up on this foundation, offers broader features of interest, which excite wonder and interest from whichever point of view regarded. We doubt whether the current and future developments of chemical science will prove attractive in the same sense.

Of the problems of more general import now engaging the active work of investigators, we may cite the following as having a direct connexion with our subject: *the theory of solution*, the mechanism of the process, and the actual molecular condition of substances in solution; more broadly, the actual configuration of molecules in the various states of aggregation of matter, and the connexion of physical properties with the order of configuration.

The *theory of assimilation* in the plant world. How radiant energy is brought in the plant cell to act upon such unpromising materials as carbonic acid and water and mould them into starch, cellulose, &c. The *theory of photographic action* in the narrower sense: what is the actual meaning of the "invisible image" produced by the impact of light on the prepared plate?

The connexion of these groups of phenomena with one another may not be obvious, and it would take us too far afield to demonstrate their intimate relationships to those who have not as yet given any thought to the subject. It is sufficient for our present purposes to remind photographers that they are moving in very good company as regards the science of their art. We may go further in stating that the science of photography is intimately bound up with coming developments of the greatest moment.

It is important therefore that its working basis should be broadened as much as possible, and to include all substances or materials calculated to contribute. We cannot help thinking that cellulose is destined to play a more important part than heretofore, if not in the art, at least in its scientific developments.

This is our preliminary answer in general terms to the question, "What has cellulose to do with photography?" We shall now demonstrate the more important properties of the substance in the hope of suggesting a few subjects of investigation and practical inquiry, which in the hands of experts should lead to results.

The external or mechanical properties of cellulose are remarkable, and there can be no better demonstration of the wide range of variations of aggregation and structure which are conditioned by these properties than an exhibition of specimens of cellulose in its most characteristic forms, natural and artificial.

Here we have, of the former group, the fibres—cotton, rhea, calotropis; side by side we will place the new artificial silk or "lustra-cellulose," which has recently been the subject of much writing, *ad captandum populum*, in the daily press. Far be it from us to endeavour to invade the "precious" incredulity with which many will meet the statement that this "silk" is identically the same in substance as cotton. As a matter perhaps of unpleasant duty, we have to point out that its brilliant lustre is due merely to the fact that it is a solid cylinder of smooth and regular outline, whereas the cotton fibre is a flattened tube with membranous walls. The form of the "silk" favours regular and maximum reflection of light, that of the cotton favours the scattering and breaking up of the incident light.

Here we have a coarser thread, also prepared in continuous length by squirting a viscous solution of cellulose into a liquid which precipitates or solidifies it. This thread is carbonised for making the filaments of the electric incandescent light, the resulting carbon having great compactness or density. Here, again, we have the cellulose in the form of artificially prepared films, which are transparent and of great tensile strength. Again we have the cellulose in masses of a firm resistant jelly, a form in which it separates, combined with water, from certain aqueous solutions to be afterwards described. In this form it has considerable elasticity, approximating in the mass to that of indiarubber, though without the exceptional texture of the hydrocarbon. This hydrate parts with its water with extreme slowness, and the cellulose molecules in aggregating together constitute a solid of extraordinary hardness and taking an extremely high polish.

These solids are so dense in texture that they are hardly amenable to wood-turning machinery, and the usual comment which is passed on a casual inspection is that they must have been submitted to an enormous pressure. As we have seen, on the other hand, the only factor involved is the extraordinary cohesion of the cellulose molecules or particles. Of course, in the natural world, cellulose and cellulose compounds, which constitute the entire framework of the vegetable world, present themselves in an imposing array of structural forms, from the tenderest silky mycelium of a fungus to the densest of woods, such as lignum vitæ. But in these natural forms there are considerable variations of chemical composition which somewhat invalidate comparisons. We have therefore chosen the various forms of the pure substance, natural and artificial, as an object-lesson of the great diversity of structural form which one and the same substance may assume. But we have now to deal with the more interesting question of the chemistry of this substance. So far we have remained in the region of sense impressions; the province of the chemist is in the sub-sensible region, which can only be entered through the channels of the imagination. At the same time the results of the chemist can be very well appreciated apart from a close study of their theoretical basis, and we must endeavour to give a brief chemical history of cellulose from this more limited practical point of view.

Cellulose is, for a compound of carbon, hydrogen, and oxygen, a body of remarkable inertness. It entirely resists a number of very severe treatments, more especially is able to withstand the action of alkalies at high temperatures. It is difficult of attack by oxidising agents. The industrial value of cellulose and its unique position and functions in the vegetable world are largely due to these negative characteristics. If we compare cellulose with the well-known substance starch, to which it is in many respects nearly related, we find that both are aggregates of sugar or glucose groups.

Starch, on the one hand, is soluble in water, and easily broken down in solution by certain ferments to the simple sugars of which it may be regarded as compounded. Cellulose is insoluble in water, and can only be resolved into sugars by the action of powerful reagents, such as sulphuric acid.

In its original fibrous and insoluble form, cellulose is therefore a very unattractive substance. It is useful to the photographer in the various forms of paper which are employed in the art; but in these uses the negative characteristics of the substance are to the fore, and we shall therefore pass them by.

Special interest, however, attaches to cellulose when it is obtained in solution. There are three groups of treatments for obtaining such solutions.

(1) There are certain compounds of the metals which in aqueous solution dissolve cellulose directly:—

(*a*) Zinc chloride. When warmed with a forty per cent. solution of this salt, cellulose swells up to a gelatinous mass, and finally dissolves to a homogeneous viscous solution. The cellulose is reprecipitated in flocculent masses on dilution with water, the precipitate retaining a large proportion of zinc oxide approximately in the proportion $2C_6H_{10}O_5.ZnO$.

By alcohol the compound is precipitated in a tenacious homogeneous form—*i.e.*, in films or threads, according to the method of bringing the liquids together.

We have often wondered why photographers have made no use of this solution. It certainly lends itself to the manipulations with which the craft is familiar, and appears to offer a method of preparing a suitable medium for carrying the photo-sensitive substance, whether on glass or paper. Certainly it should be found useful in investigations, and we commend the preparation to notice as affording a plastic modification of cellulose—one, moreover, which is easily obtained.

(*b*) Zinc chloride dissolved in hydrochloric acid.

A solution of the salt in twice its weight of the aqueous acid acts instantaneously on cellulose in the cold, and for many uses in research work has therefore important advantages over the preceding solvents.

Photographers may make some interesting demonstrations with this solution. If a platinum print be laid face downwards upon a resistant surface—*e.g.*, glass, porcelain, or asbestos—and the reagent poured upon the paper, the solution of the paper is accompanied by the appearance of the photograph in full detail. The effects are interesting, and, as every chemical effect finds a practical application somewhere or other, we quite expect to see this solvent taken advantage of.

We have now described two solvents of cellulose—one a normal salt, a compound of a metallic oxide and an acid in equivalent proportions; and one an acid solution of this salt. We have now to describe an alkaline solvent, a compound of a metallic oxide which may be regarded as having acid properties, with the alkali ammonia.

(*c*) Solutions of cuprammonium are prepared by adding precipitated copper oxide to strong aqueous ammonia. Crystallised copper sulphate is dissolved in water, and to the cold solution caustic soda (solution) is added. The blue gelatinous precipitate of copper oxide (hydrated) is well washed on a cloth filter, squeezed and pressed, and stirred into strong aqueous ammonia.*

The solution should contain the reagent in the proportion NH_3, 10 to 16 per cent., C_4O. 25 to 30 per cent.

The solution may be also prepared by placing scrap copper in contact with very strong ammonia and in presence of air. The metal is oxidised by the oxygen of the air, and the oxide dissolved by the ammonia.

This solution rapidly attacks cellulose in the cold, and forms usually gelatinous or ropy liquids. The reaction has been largely used in the arts for treating cloth and paper; the treatment with the solvent, followed by evaporation of the solvent on the fabric, leaves the surface in a condition impervious to moisture. As far as we know, there have been no applications of this solution or the reaction in photography. But we see certain possibilities of results, and we have therefore included it in our list of cellulose products.

These three solvents constitute a group; their action depends upon reactions of a not very definite order, speaking chemically. They may be broadly described as an interaction of acid and basic groups of the cellulose itself, reciprocally with basic and acid groups of the respective solvents; there results therefore in each case a species of soluble double salt.

We cannot here discuss the theoretical bearing of the reactions, and we must refer those who wish to follow them up to the special literature of the subject.

We now pass to methods of dissolving cellulose which depend upon well-defined reactions, in which the cellulose is converted into derivatives or compounds belonging to well-known groups. These reactions are reactions of synthesis, and take place with those groups of the cellulose molecule the presence of which make it an alcohol. The reactions of cellulose are, in fact, exclusively those which belong to the group of alcohols. Thus, if we write ordinary alcohol, the arch-fiend of the "blue-ribbon" philosophers, as $C_2H_5.OH$, we may write cellulose, for the purpose of this discussion, as $C_6H_6O.(OH)_4$. It is the OH groups which are alcoholic.

We shall now describe one of the most characteristic of such compounds of cellulose, which occupies an intermediate position between the ill-defined compounds above described and a group to be subsequently dealt with in conclusion. It is a compound soluble in water in all proportions, whereas in the latter group, that of the acid ethers of cellulose, the relationship to water becomes negative: they are eminently water-resisting compounds. In respect of this property, therefore, the transition is maintained. Cellulose is attacked by solution of the caustic alkalies at a certain degree of concentration, *e.g.*, at and above a strength represented by twelve per cent., Na_2O on the solution. The effect on the fibrous celluloses is remarkable. They swell up, shrinking considerably in length, and become translucent or transparent. The effects are due to the definite combination of the cellulose and alkali in the proportion $C_6H_{10}O_5 : Na_2O$. We may express the compound "alkali cellulose" in the abbreviated form, $X\begin{matrix}ONa\\ONa\end{matrix}$. This compound in the presence of water reacts with carbon bisulphide in the cold. The molecules unite thus, $X\begin{matrix}ONa\\ONa\end{matrix} + CS_2$. The resulting sulpho-carbonate of cellulose may be written as $CS\begin{matrix}OX.ONA.\\SNa.\end{matrix}$ The compound is perfectly soluble in water, and the solution is now employed on the large scale in several industries, being known as "viscose." Its most important property is that of decomposing spontaneously on keeping, the cellulose being regenerated in compact coherent masses. The decomposition is more rapid at high temperatures.

* See also *Ber. Deutsch. Chem. Ges.*, 13, 1822.

Obtained as described, the solution has a yellow colour, due to by-products of the reaction. The pure compound is obtained by treating the crude solution with a saturated solution of common salt or with alcohol. Both reagents precipitate the pure cellulose sulpho-carbonate. If the liquids are poured into the viscose, the compound is precipitated in flocculent masses; but, if the viscose be spread upon a glass plate and the whole submerged beneath the precipitating solution, the compound is obtained as a coherent film of a greenish colour.

CROSS, BEVAN AND BEADLE.

(*To be continued.*)

PHOTOGRAPHY IN THE INTERIOR OF BRITISH GUIANA.

[British Guiana Graphic Club.]

My first experience of photography in the bush was in 1884–5, when I accompanied Mr. E. Im-Thurn to Roraima. At this time there were, I think, but few amateur photographers in the colony, as I remember I found it particularly difficult to get any dry plates for my camera, which was a quarter-plate by Lancaster, kindly lent to me by the late Mr. Glaisher, Curator of the Museum.

I went to one or two of the professional photographers, but they said they were unable to let me have any plates, as their own supplies were small, and they might at any time run short. At the eleventh hour, I may say, Mr. Gilzean, who was then at Anna Regina, kindly lent me, through Mr. Im-Thurn, some three dozen plates, and with these I tried my best to secure good pictures of Roraima and the adjacent country.

I had decided to take a camera with me only a few days before we left Bartica, and I had not had any lessons or practice at all in photography, and therefore made up my mind to just expose the plates and repack them for development in Georgetown on our return.

There was only one double back to my camera, so my chances of taking many pictures at a time were very limited. To remedy this, however, I obtained from Mr. Norton, who was then established in Georgetown, a small collapsible changing box, made of cloth, covered with pasteboard, and provided with a red-fabric light side, and a pair of observing glasses through which the work of plate-changing could be easily seen and carried out, the hands being introduced into the box by two sleeves fitted with elastic, which tightened over the arms. After taking pictures on the two plates in the double back I had to use my changing box for refilling, and at the same time repacked the two plates that had been used.

In this way I managed to expose all the plates, but, of course, had no idea of the value of my results, which, I regret to say, were far from satisfactory. One of my minor difficulties was the instability of the camera which had a nervous, irresponsible way of supporting itself, and in the occasional strong gusts of wind which prevail at certain seasons on the mountain, and especially about 5300 feet up, the camera and all blew bodily over. I got over this trouble, after one or two falls of my instrument, by suspending a heavy stone from the centre of the wooden platform under the bellows body of the camera, but it always took a considerable time to prepare for action before a stone suitable for the purpose could be found and tied up in position.

When I got back to Georgetown the plates were submitted to Norton for development, and were all pronounced by him to be suffering from red fog; some of them were over-exposed and yet others under-exposed. I show here some prints taken from the best of the negatives.

I found the plates travelled fairly well, they were carried in their own packages wrapped up in brown paper, and placed inside tin boxes, and were, at times, exposed to very considerable heat, both when taken to and from Roraima, over the open savannah country, where the sun beat down fiercely all day long on the backs of the Indian porters who carried our luggage day by day from one camp to another.

I think the chief reason why the plates did not turn out well was my entire ignorance of photography at the time, but I also fancy that my changing box may not have been quite light-tight. I intended to have brought it down to town for Norton to test it, but it had to be left behind at the mission in the Potaro River, along with some other things, as we had very little room for the boats in which we came to Bartica from the mission, and I never saw my belongings again.

Thus ended my first endeavours in photography, and I did not take it up hotly again till 1887, when I purchased the half-plate camera I always use now; and, after some instructions from Norton, I provided myself with six dozen of Rouch's plates, and in September, 1887, left Georgetown for the Puruni River, where I remained seven months, and where I had a regular camp, but no dark room for developing plates or other photographic work.

On the way from Bartica I took a few pictures, intending to work them up when I reached my destination, as I had no opportunities to do so whilst on the journey. The plates I changed at night by a red lamp, and repacked the exposed ones in their original packages. When I got to my chief camp on the Puruni, I found a small house already built, and which had been occupied by the surveyor, who had been there before me. The sides were roughly wattled and let in the daylight freely, so all my developing work had to be done at night.

I fixed up a couple of shelves, one to hold my developing dishes and lamp, and, above this, another, on which I placed a bucket filled with water, which I used by means of a flexible indiarubber tube employed as a syphon, the water being shut off when not required by a spring paper-clip.

The bush water, I found, did not injure the plates or stain them in any way, though it was not quite colourless, being of a light brown; and I used to find that, if the alum dish was allowed to stand till morning, there was always a slight brown scum at the bottom, whilst the rest of the solution was clear. One of my chief troubles in developing was the lightning, which on certain nights compelled me to give up work altogether, and which fogged several of my plates when a sudden flash illuminated the whole house and the surrounding bush. On what I called regular lightning nights I did not attempt to work, but, as I have just said, I lost a few plates by lightning when I commenced work on what appeared to be a favourable night, in which, however, there were unexpected lightning flashes.

Another trouble was the presence of fireflies and the fire beetles, which were occasionally quite numerous, and seemed to have a partiality for a dull red light such as my lamp emitted. I don't know what is the actinic force of a firefly's or fire beetle's light, but I ascribed the fogging of some of my plates to their being exposed to this light; and I am afraid the force of my language exceeded that of the insects' light.

For the final washing of my plates, I used to subject them, after a copious washing with the water through the indiarubber tube, to a soaking of a couple of hours in a bucket of water. I found this imperative, as I could not store enough water before night fell for all the work I wished to do, and I always refrained from getting more from the river at night, as the bank was high and precipitous, and on the only occasion on which I tried to get water at night I nearly fell into the river.

My present practice, when photographing in the bush, is to leave development till I return to town, unless a favourable opportunity offers of using a dark room, or unless I can get some house where I am likely to stay for a day or two, and where the plates, after thorough washing, can have time to dry. This I don't look upon as a satisfactory plan, owing to the fact that the picture of an effective view of some spot visited on a journey may turn out very badly, and the place may not be revisited, or, if revisited, the attendant circumstances of time, weather, and light, may not be at all favourable for a successful picture.

On the few occasions on which I have developed whilst actually travelling, I have found that, owing to the great dampness of the air, my plates did not dry by next morning at half-past six, by which time everybody was ready to start on the next stage of the journey, and the plates had to be put into light-tight tin boxes, grooved inside to hold plates. Once I found some large ants had taken a fancy to the films in the night, and had eaten off most of the pictures, again a vigorous boviander kicked a mass of sand over the negatives, and another time I found a dog belonging to the boat captain industriously licking the negatives, with strips of gelatine hanging on to each side of his mouth. As one's position is constantly changing during a bush journey, it often happens that the same route is followed when returning to Georgetown, chances occur of taking pictures of places which have been already photographed, but which have not turned out well, and I hope to be able, in future, to allow myself sufficient time always to develop all my plates when I have got to the end of my journey from town, so that I may repair any deficiencies on my return to town if necessary.

Concentrated developers and vulcanite dishes reduce the bulk of the load when travelling, and should be adopted. The plates themselves, if the journey be a long one, and the stay from town extend over some months, should be specially packed, and particularly so if it be intended to leave development till the return to town, as I found during my stay in the Puruni, although I had each dozen of plates packed in soldered tin cases before I left town, and did not open the last two dozen till about three weeks before I returned to Georgetown, that some active deteriorating effect, the cause of which I am ignorant, had set in, and I was unable to get a single good result from the last plates.

I submit for your inspection one of these, and would like to hear your views on it. I had many others, which I regret to say I have been unable to find, and may have possibly destroyed them.

H. I. Perkins, F.R.G.S., *Acting Commissioner of Mines, British Guiana.*

STEINHEIL'S IMPROVEMENTS IN LENSES.

Herr R. Steinheil, the patentee, says: "The discovery of new sorts of glass has rendered it possible to produce two kinds of lenses which consist of two positive, equal or similar parts, each of which is in itself chromatically, spherically, and astigmatically corrected, consequently the finished lens contains these three corrections, whereas formerly lenses of two positive, equal or similar parts, could only be corrected chromatically and spherically, as, in attempting to effect the astigmatic correction, an unsymmetrical construction resulted. Astigmatic corrections can only be made on a divisional surface of two mediums which presents the concave side to the greater refractive medium, whilst the spherical correction can only be made on a divisional surface which presents the concave side to the lesser refractive medium.

"With this principle as a basis, lenses can be constructed out of symmetrical or similar halves, which on the first divisional surface of the separate halves are corrected astigmatically, and on the second surface are corrected spherically. Lenses so constructed have this characteristic, that a positive lens is enclosed by a double convex one, and by a double concave one, both of which have a higher refractive power than the enclosed positive lens.

"The lens shown on the accompanying drawings consists of symmetrical or similar halves, differing only in proportion, each of which is composed of three cemented lenses. The middle lens is a positive one, and is enclosed by a double convex lens and by a double concave lens,

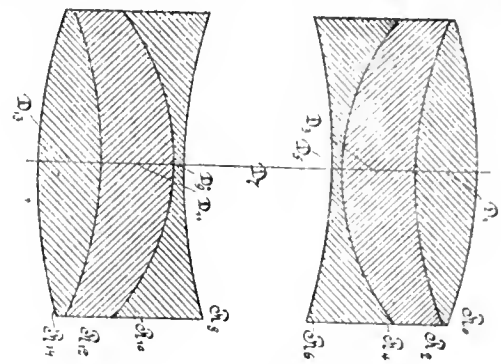


Fig. I.

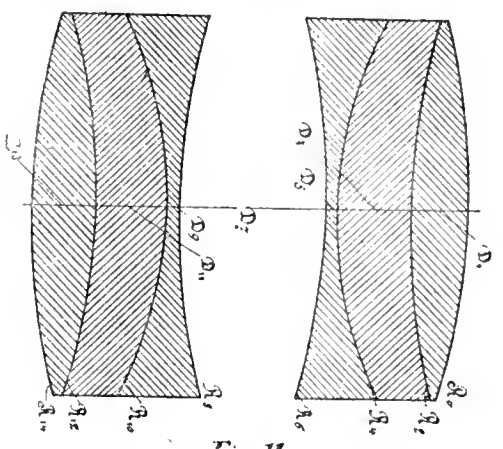

Fig. II.

each of the two latter possessing stronger refractive power than the enclosed positive lens.

"Fig. 1.—Taking a focal distance of 492 mm., a lens constructed on the principle of this invention, with a degree of exposure of 1 : 6, would have the following elements:—

$x\,0 = 41.$

R 0 = R 14 = + 173,00 mm. R 2 = R 12 = ± 139,66 „	D 1 = D 13 = 20 mm.	n D = 1,61003 n F = 1,61759
R 4 = R 10 = + 77,805 „	D 3 = D 11 = 25 mm.	n D = 1,51874 n F = 1,52561
R 6 = R 8 = − 202,47 „	D 5 = D 9 = 4 mm.	n D = 1,56370 n F = 1,57160

Difference D 7 = 50

n D and n F = the indices of refraction for the Frauenhofer lines D F.
R = Radii. D = Thickness.
$x\,0$ = Radius of lens aperture.

"Fig. 2.—With a focal distance of 476 mm., with an exposure proportion of 1 : 4, the elements of a lens constructed from the foregoing point of view are the following:—

$x\,0 = 59{,}5$

R 0 = R 14 = + 229 R 2 = R 12 = ± 562,95	n D = 1,62356 n F = 1,63498
R 4 = R 10 = ± 142,03	n D = 1,50786 n F = 1,51351
R 6 = R 8 = − 490,196	n D = 1,60304 n F = 1,61128

D 1 = D 13 = 20; D 3 = D 11 = 25; D 5 = D 9 = 4; Difference, D 7 = 50

The claim is:—A lens consisting of symmetrical, or similar halves, differing only in proportion, each of which is composed of three

cemented lenses, namely, a positive lens, a double convex lens and a double concave lens, the two latter enclosing the former, and both of said double convex and double concave lenses possessing stronger refractive powers than the enclosed positive lens.

WHAT IS IT?

[London and Provincial Photographic Association.]

I NEED not apologise for bringing this subject before you to-night, but, from numerous failures and peculiarities observed in plates by experimentalists, it warrants a close investigation. A few weeks ago Mr. Hodd exhibited here several negatives somewhat strangely marked. These marks, although not new to us, are very puzzling. In them I at once recognised an old enemy, and recalled to my mind the fact that I had several examples by me of a more marked character, taken about eight years since. I exhibited them at the time, and, although some of our members ventured theories, yet I was not satisfied, still living in hopes that the mystery would be solved some day. When an effect is produced from more than one cause, the difficulties of investigation are very great.

Here is a plate that has been placed, film side, in contact with a piece of glass, in order to prevent any chemical action; the two plates were wrapped up in brown paper, and a small hole torn through the wrapper. Several thicknesses of white cigarette papers were placed over the hole, then the parcel was further covered with more brown paper; this packet was carefully put away for about three months; then, an energetic developer applied, a dark mark came up corresponding with the hole in the inner paper. I don't for one moment think that the X rays have anything to do with the phenomena; it is evidently a phosphorescent action emanating from the cigarette papers.

Who amongst us has not been a sufferer from markings on the negatives, caused by the separating cards? Believing that it was a chemical action, I had some cards dried and thoroughly saturated with paraffin wax. I used them as separators. The cure was worse than the disease; the markings gradually spread almost into the middle of the plate. This must be phosphorescence in the cardboard. I have lately examined some plates, made about ten years, that were separated with tinfoil. They developed clean and clear to the edges, thereby showing the valve of tinfoil as a separator. The expense might be less than cardboard. Three pieces, three-quarters by half an inch, are sufficient for twelve quarter-plates. See, here are several negatives that represent an accelerated and restrained action. They are drop-shutter exposures, and taken on board a P. and O. steamer off Colombo. You will notice that, in one, half of the plate is comparatively insensitive—that is a restrained effect; in another you will perceive an accelerated effect; another where the image has almost disappeared; and another where the reversed action has commenced. How can we account for this? In one we have an exudation from the dark slide, which attacks the film (a sort of waterproofing), thereby preventing the equal reduction. I have carefully tested this by subjecting a plate, or part of a plate, to the vapour of turpentine. If I take a plate and put it in a dark slide, and keep it close to a small, wet pad, say of chamois leather, leave it there for a quarter of an hour in the dark room, then I quickly examine the plate by reflected light, I notice that the plate is glossy, *i.e.*, the part that was near the damp pad. This moisture acts as a restrainer, and, if a very energetic developer be applied, the film will slightly fog, leaving the moist part clearer. This is easily explained—moisture is the delinquent.

I have discovered that moisture under varied circumstances will give different effects. Here is a plate that has been cut in half; one half has been exposed in a dark slide for about twenty minutes in sunlight, the other half exposed the same length of time, the only difference being that a stencil plate, cut out of leather, has been glued to the shutter, a brass escutcheon being fixed, and the leather plate moistened with water. Both halves of the plate were placed in a strong developer, with the result that a strong impression of the escutcheon plate and leather is visible. Examined carefully, you will see that the part of the brass plate nearest the plate is less sharp. This I cannot understand. If a moist piece of leather is put at one end of a dark slide, and the sun allowed to play on the dark slide through the leather for about twenty minutes, on development you may have a light action more apparent at the moist end, or you may have a restraining effect, as aforesaid.

As far as the sunlight experiments are considered, I think the X rays are to be credited; but, at the same time, credit may be given where it is not due. The plate-makers have a legitimate excuse when plates give out or deteriorate. Many dealers keep their stock of plates on shelves, exposed to strong light, and, if a small amount of moisture is present, it is only a matter of time before the plates go bad.

I might argue that, as the X rays do not readily pass through glass, that might account for markings round the negative. I may mention that the plates I experimented with with the tin foil were kept in the dark. I am continuing experiments, but I cannot hope to exhaust them. suffice it to say, I have some celluloid receivers made, by which I intend to pass the light through various substances. Some years ago Professor Gladstone showed some interesting experiments at one of the British Association meetings showing the absorbent of light property of disulphate of quinine. I repeated the experiments successfully. He demonstrated that, when a wine glass half full of ink and another half full of a colourless solution of quinine were photographed together, it was impossible to distinguish one from another. It has also been stated that light passed through a cell of quinine, that it rendered the light safe for wet-plate photography. This I did not find correct, yet I have made an experiment which tends to show that quinine does exercise some influence on the invisible rays passing through dark slides.

I think the information suggested by these experiments valuable to plate-makers; in the mean time, I would suggest separating by tinfoil, keeping the plates in metal boxes and in the dark.

In conclusion, I will ask an oft-repeated question (which is usually answered by asking another), Why is a gelatine plate more opaque when wet than dry? Usual answer, What good will it do you if you knew? But I want to know.

A. L. HENDERSON.

ANIMATED PHOTOGRAPHS AT MARLBOROUGH HOUSE.

ON Tuesday evening, the 21st inst., Mr. Birt Acres had the honour of showing some of his animated photographs at Marlborough House, by command of H.R.H. the Prince of Wales (through General Sir Dighton Probyn), before the distinguished company invited by the Prince and Princess of Wales to the dinner in honour of the marriage of H.R.H. the Princess Maud of Wales to H.R.H. Prince Charles of Denmark. The demonstration was given in a specially arranged marquee in the grounds of Marlborough House. The company, which numbered about seventy-five, included the following: H.R.H. the Prince of Wales, H.R.H. the Princess of Wales, T.R.H. the Crown Prince and Crown Princess of Denmark, T.R.H. the Crown Prince and Princess of Sparta, H.R.H. Prince Nicholas of Greece, T.R.H. the Duke and Duchess of Connaught, T.R.H. Prince and Princess Christian of Schleswig-Holstein and her Highness Princess Victoria of Schleswig-Holstein, H.R.H. Princess Louise (Marchioness of Lorne) and the Marquis of Lorne, H.R.H. the Duchess of Albany and her Serene Highness the Princess Elizabeth of Waldeck-Pyrmont, H.R.H. Prince Christian of Denmark, H.R.H. Prince Charles of Denmark, H.R.H. Prince Harold of Denmark, H.R.H. Princess Ingeborg of Denmark, H.R.H. Princess Thyra of Denmark, T.R.H. the Duke and Duchess of York, H.R.H. Princess Louise (Duchess of Fife) and the Duke of Fife, H.R.H. Princess Victoria of Wales, H.R.H. Princess Maud of Wales, T.R.H. Prince and Princess Philip of Saxe-Coburg, H.R.H. Princess Frederick of Schaumberg-Lippe and his Highness Prince Frederick of Schaumberg-Lippe, H.R.H. the Duke of Cambridge, his Highness Prince Christian Victor of Schleswig-Holstein, their Highnesses Prince and Princess Edward of Saxe-Weimar, his Highness the Duke of Teck, H.S.H. Princess Victoria of Hohenlohe-Langenburg and Countess Feodora and Helena Gleichen, T.S.H. the Prince and Princess Adolphus of Teck, Count Gleichen, Count and Countess Siegfried Clary and Countess I. Kinsky, the Danish Minister and Madame de Bille, the Swedish Minister and Countess C. Lewenhaupt, the Greek Chargé d'Affaires and Madame Metaxa and Count and Countess Ahlefeldt Laurvig, Mdlle. de Wimpffen, Count Moltke, Captain Bull, Lieut. Lewald and Col. the Hon. Hy. Byng, Mdlle. Condostavalo and Col. Sapountzakis, Lady Mary Lygon, the Hon. Derek Keppell and Sir Charles Cust and Comtesse Sermade, Baron Gablenz and Captain W. Campbell. Lord and Lady Colville of Culross, Lord and Lady Suffield, General Sir Dighton and Lady Probyn, Sir Francis and the Hon. Lady Knollys, Major-General and the Hon. Mrs. A. Ellis, Major-General and Mrs. S. Clarke, Miss Knollys, Commander the Hon. S. Fortescue, the Hon. Stonor, and Mr. Holzmann, &c.

The programme consisted of twenty-one scenes as follows:—

1, *Capstone Parade, Ilfracombe.* 2, *Children Playing.* 3, *Great Northern Railway—Departure of an East Coast Express.* 4, *The Derby*, 1895. 5, *Niagara Falls* (in three tableaux): No. 1, The Upper River just above the Falls; 2, The Falls in Winter; 3, The Whirlpool Rapids. 6, *The German Emperor Reviewing his Guard previous to the opening of the Kiel Canal, June*, 1895. 7, Carpenter's Shop Scene, *Refreshments.* 8, *The Boxing Kangaroo.* 9, *The arrest of a Pickpocket.* 10, *A Visit to the Zoo.* 11, *Yarmouth Fishing Boats Leaving Harbour.* 12, *Golf Extraordinary.* 13, *Tom Merry* (lightning artist) *drawing Mr. Gladstone.* 14, *Tom Merry* (lightning artist) *drawing Lord Salisbury* 15, *Boxing Match in two rounds by Sergeant Instructor F. Burrett and Sergeant Pope.* 16, *Highgate Tunnel.* 17, *Henley Regatta.* 18, *The Derby*, 1896. Clearing the Course; the Preliminary Parade; the Race: "Persimmon" wins; the rush, intense enthusiasm, waving of hats, &c. 19, *Broadway, New York.* 20, *A "South Wester."* 21, *H.R.H. The Prince of Wales accompanied by T.R.H. The Prince of Wales, Princess Victoria, and Princess Maud, arriving at the Cardiff Exhibition, June* 27, 1896.

All the pictures were well received, but in the last picture Royalty recognised themselves as they had never been portrayed before; and, as the figures were thrown life size on the screen and the portraits were clear and distinct and readily recognisable, this picture met with the most enthusiastic reception, and, in spite of the fact that the programme was an exceptionally long one, this last picture had to be repeated.

At the conclusion, H.R.H. the Prince of Wales personally thanked Mr. Birt Acres.

The disc thrown on the screen was perhaps the largest that has been attempted in this class of work, measuring as it did about eleven feet by

eight feet six inches, and the light throughout was excellent, largely due to the facts that transparent films were used.

H.R.H. the Prince of Wales gave Mr. Acres permission to take kinetic photographs on the following day at the wedding, and we understand that Mr. Acres secured excellent negatives each 80 feet long and consisting of about 1500 separate photographs of the departure of the royal party from Marlborough House and also of the return to Marlborough House after the ceremony at Buckingham Palace. Later on, Mr. Acres secured an excellent negative on the Lawn of Marlborough House of the departure of the royal couple for Sandringham.

Mr. Acres was greatly impressed with the kindness and consideration of their Royal Highnesses, as every facility was granted to him to ensure satisfactory results both at the demonstration on Tuesday evening and also while the photographs were being taken on the wedding day.

The Inquirer.

*** *In this column we shall, from time to time, print questions that may be addressed to individual contributors to our pages, or such as are sent to us with the view of eliciting information from a variety of sources. We invite the co-operation of our readers in rendering this feature of the* JOURNAL *useful and instructive.*

MAGNESIUM LIGHT. — J. H. asks for a comparison between sun light and magnesium. As I use magnesium in preparing the standard tint for my actinometer, and made careful trials for the purpose, I can give him some information. I found that two grains of magnesium ribbon, burned in a coil at a distance of four and three-quarter inches from the object, had the same actinic power as two seconds' exposure to mid-day June sunlight and skylight.—ALFRED WATKINS.

LENS QUERY.—NON-MATHEMATICAL READER writes: "Distance of object and focus of lens being known, to find size of image also, size of object and focus being known, to find distance at which an image of a certain size can be obtained. Can you give me formulæ for working out these calculations?"—We cannot go into the matter here, but, if our correspondent will bring a little thought and common sense to bear on the table of conjugate foci in the ALMANAC, he will not have much difficulty in arriving at a solution of both questions.

CHROMATE OF SILVER IN EMULSION (To "Billericay").—It seems to me that there must have been free nitrate of silver present as well as carbonate in the film referred to by your correspondent, in which case a somewhat complicated reaction would result. In the first place acid chromate of silver would be formed by the mutual decomposition of the silver nitrate and the bichromate, and this is soluble in water, while any neutral chromate formed at the expense of the silver carbonate would probably be partially or wholly decomposed and rendered soluble by the nitrate of potash formed in the first reaction. In order to secure a film of insoluble or neutral chromate of silver, there should be nothing present but carbonate of silver."—SYNTAX.

UNMOUNTING GELATINE PRINTS. — ALBUMEN writes: "Will any one kindly recommend a reliable method of unmounting gelatino-chloride prints that have apparently been put on the cards with a gelatine mountant? I have a number of such prints to take off the cards and transfer to an album or scrap-book, and, as they are of some value to the owner, I dare not risk spoiling them. I have soaked them in cold, and even in slightly, warm water, but cannot get the slightest sign of detachment. With albumen prints it would be an easy matter to use hot water, but this is out of the question with gelatine, and to render the gelatine print insoluble would also result in a like action upon the mountant. Is there any method of removing them?"

PHOTOGRAPHING THE MOON. — ASTRO asks: "Is it possible to take instantaneous photographs of the moon sufficiently sharp to bear subsequent enlargement? I have a four-foot focus (about) achromatic lens, which, I am told, is a telescope lens; if I mount this in a long tube, can I take photographs of the moon and stars without any driving apparatus and with a moderate-sized stop? Will the pictures be sufficiently sharp for, say, lantern slides? Or would the lens work with full aperture?—it is four inches in diameter, and therefore equal to about *f*·48. Can you give me any idea of the exposure necessary with quick commercial plates, and whether it is worth my while to attempt astronomical photography under these conditions?"—Perhaps some of our readers who are familiar with this class of work will supply the information.

ALKALINE INTENSIFICATION OF WET PLATES.—Without doubt, "Wet Plate" (page 444) is correct in what he says with regard to the retarding influence of the layer of silver deposited by the first developer, but this may, especially in the case of under-exposure, be an argument in favour of the alkaline method of intensification. With a properly prepared bath film, there is very little difference in the sensitiveness whether iron or alkaline pyro be used; but with a collodion emulsion film, or when pyro and silver is employed as the developer, the alkaline method is much the quicker. Now, in case of under-exposure, whatever may be the first developer employed, obviously there still remains the small proportion of haloid that has been acted on by light, and which, being practically uncovered by any silver deposit, or a very slight one, is fully exposed to the reducing action of the alkaline intensifier, while the better-exposed portions, covered with a thicker coating of reduced metal, are more thoroughly protected, and do not undergo proportionate reduction. Thus, this style of intensification would seem calculated —as it actually does—by its selective action to favour the production of detail and softness, and this is very markedly the case when acid pyro is the first developer used.—SYNTAX.

SULPHOCYANIDE TONING.—TWO YEARS AN AMATEUR says: "I have hitherto met with very fair success in printing, using —— and —— paper, with both of which the sulphocyanide bath gives me as good results as I could desire; but, recently, my dealer, being out of both those brands, sent me —— instead. Now, although the instructions give the sulphocyanide amongst other formulæ, I cannot, with this paper, work it at all. If the toning bath be new and of full strength, the first few prints pass through it fairly well; but, after less than one-fourth of the proper number have been toned, it becomes very slow in action, and eventually refuses to tone at all. Adding more gold 'wakens it up' a little: but, although the image may tone, the high lights and half gradations take a variety of tints—pink, yellow, and even green—and, after fixing, the things are simply horrible. I cannot get the paper changed, as the dealer implies that it is my fault, not that of the paper. Have you, or any of your readers, had similar experience with this special brand of paper?"—It is against our rules to discuss the relative working merits of commercial preparations, but we may say that, with other toning formulæ, we have used this brand of paper with satisfaction. Why not try acetate or phosphate, both of which work well?

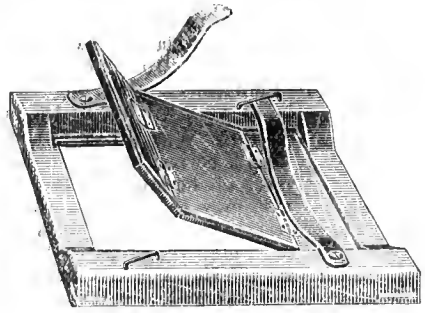
CHROMATE OF SILVER (To "Billericay").—J. P. writes: "Having made the statement to which this correspondent alludes, namely, that an insoluble chromate of silver is formed by the action of bichromate of potash on carbonate of silver, I suppose I must, as I am prepared to, justify it. If 'Billericay' will heat an emulsion, or an emulsion film, containing nothing but pure carbonate of silver with bichromate of potash, he will find the fact as I have stated; the chromate of silver will remain, and will withstand any amount of washing. If, however, there be any soluble nitrate present, either in the form of decomposition products or of free silver nitrate, then, no doubt, the chromate formed will be more or less soluble, as he states, being in the first case acted upon by the nitrate of potash, soda, or ammonia, as the case may be; on the other, by the nitric acid set free by the reaction of the silver nitrate with the bichromate. I imagine that 'Billericay' has operated upon an emulsion made by double decomposition of the salts in the gelatine, but this is not the best way of making a carbonate emulsion. If the carbonate of silver be precipitated from aqueous solutions of the salts and washed, it will readily emulsify in warm gelatine, and bichromate may be added to it without fear of loss, or the film of gelatino-carbonate may be dried and sensitised with bichromate in the same manner as carbon tissue."

Our Editorial Table.

The "Mosely" View and a Half-Printing Frame.

G. Houghton & Son, 89, High Holborn, W.C.

This frame is novel in construction. It has a double-jointed back, which allows of a three-quarter view of the print being obtained at either end, thus permitting every part to be examined. The print is



held firmly, so that it cannot possibly move during examination. The advantage of being able to view the whole of the print without incurring the risk of displacing it should render the "Mosely" frame very popular. It is cheap and well made.

Marion's Large Bamboo Double Mirror.

Marion & Co., Soho-square, W.

The useful accessory here illustrated will, doubtless, be found of great service in the professional studio. The mirrors are five feet

From a photo by W. & D. Downey, Ebury-street.

long and two feet broad, and are of plate. Full-length reflections are to be obtained, and it can easily be seen that many novel poses will suggest themselves to the photographer. The whole is of solid bamboo on casters.

White Enamel Bromide Paper.

Morgan & Kidd, Richmond, S.W.

The white enamel bromide paper of Messrs. Morgan & Kidd, of which they have sent us specimen prints, together with sample for trial, has a very great degree of gloss, thus imparting to the finished picture the appearance of a highly glazed collotype. This surface conduces to the obtaining of the utmost detail. In use, the manipulation of the paper does not differ from that of ordinary bromide paper. The white enamel bromide paper will doubtless be appreciated for a variety of special purposes, as the results it yields are in every respect excellent.

A Retouching Powder.

Norman Vine, 5, Elthorne-avenue, Hanwell.

This is an extremely fine impalpable powder, for imparting to unvarnished negatives a smooth matt bite for taking pencil work. It is applied by means of a fine linen rag, and can afterwards be varnished. As a substitute for matt varnish on the glass side of the negative it is also recommended. The powder appears to answer its purposes very well.

Catalogues Received.

McGhie & Co., 75, St. Vincent-street, Glasgow.

The supplemental catalogue of Messrs. McGhie is devoted to the latest introductions in lenses; finders; cameras, hand and stand; studio stands; shutters; apparatus generally; mounts; backgrounds, &c. The catalogue should be useful alike to professional and amateur, for, in the familiar phrase, it is well up to date.

David H. Hogg, 662, Craig-street, Montreal.

If we may judge by the handsome catalogue before us, Mr. Hogg holds a very prominent place amongst Canadian photographic dealers. It is a well-executed compilation, the choicest photographic goods of England and the United States being described and illustrated in its pages.

News and Notes.

Messrs. F. S. Thorn & Co., of 169, Camberwell New-road, inform us that in future their firm will be known as Thorn & Hoddle.

The Convention Group.—No. 58 is Mr. J. Houghton, of Leeds; No. 71, Mr. A. Nicholson, Leeds; No. 51, Mr. William Booth, Manchester; No. 101, Mr. Walter Booth.

The Photographic Club.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock, on Wednesday evening, August 5. Subject for discussion, *The Use of Small Cameras and the Making of Enlarged Negatives.*

Leicester and Leicestershire Photographic Society.—An Exhibition of photographic pictures will be held in the Co-operative Hall, High-street, on Tuesday, Wednesday, and Thursday, November 24–26. There will be one open competition, viz., for landscape or seascape, with or without figures, and a silver or bronze medal will be given for the best and second best single pictures. Full particulars may be obtained from the Secretary, T. Brown, 68, Church-gate, Leicester.

Mr. Jackson, of King's College, has been lately examining with the spectroscope the light emitted from different fluorescent screens under the influence of the X rays. According to last week's *Electrician*, he finds that the barium platino-cyanide and the potassium platino-cyanide give respectively the light of barium and of potassium, which is an important point, seeming to show that we are not dealing with vibrations of the molecules, but rather with some of the constituent atoms. This confirms Professor Silvanus Thompson's remark made during an address recently delivered at Oxford, that "X rays apparently can touch the atom within the molecule and set it into vibration."

A new material for filling paper has recently been introduced under the name of "nematolith." It is of a fibrous nature, and promises to prove of great utility as a filler. Chemically speaking, a member of the asbestos family, it has an advantage over the latter, owing to its freedom from the iron, lime, and sulphur compounds that are usually found in crude mineral asbestos, the raw material from which nematolith is prepared for paper-making purposes testing, on analysis, 96° of pure silicate of magnesia. It is very white, and, owing to its fibrous nature, it is readily retained by the pulp. It may be hoped that it will take the place in America of the very heavy filling of barytes there used.

An account is given in the *Physical Review*, by R. A. Millikan, of some careful tests of light emitted by glowing solids and liquids, with a view to discover the laws of its polarisation. This phenomenon is exhibited strongly by incandescent platinum, silver, gold, and by molten iron and bronze; a somewhat feebler polarisation is shown by copper, brass, lead, zinc, and solid iron. The most significant result named is that polarisation is minimum with rays emitted normally to the surface, and maximum at a grazing emission, thus indicating that the vibrations take place in a plane at right angles to the emitting surface. Glass and porcelain also emit polarised light, but to a lesser amount; fluorescent bodies do the same, so that evidently a high temperature is not necessary; and in the case of uranium glass it is said to be the green reflected light which is polarised, and not the blue incident light diffused from the surface.

THE SANDELL EXHIBITION, 1897.—This Exhibition of the work of the Managing Director of the Sandell Works Company on the Sandell plates will be opened on April 1, 1897, and continue open until May 31, at the Works. It will consist of upwards of four hundred pictures, principally 15×12, comprising Continental Views, the Halls of the City Guilds, the Guildhall and Mansion House, Gray's Inn, Lincoln's Inn, Lambeth Palace, Westminster Abbey, Windsor Castle, Pharmaceutical Society's Establishment, 1896 Convention Views. Many users of the plates have promised contributions, and the support of all interested in furthering the advance of photography is invited. The Company are prepared to pay the carriage to and fro of all exhibits.

IT is well known that the bones are relatively opaque to the X rays, and that this opacity is due to the chemical composition of the fundamental bony tissues, which are made up of calcium salts (phosphates, carbonates, and fluorides). The question would then be a natural one, whether, by introducing a salt of lime into the veins, they could be made to leave a shadow on the photographic plate. The Physical Institute at Rome has performed this experiment. Into the brachial artery of a dead body was injected a paste of sulphate of lime, sufficiently liquid to penetrate all the blood vessels, and then, after it had hardened, the hand was photographed, the Crookes' tube being held at a great distance, so that the shadows would be very sharp.—*Cosmos*, Paris.

RÖNTGEN X RAYS COMPETITION.—The council of Animals' Hospital and Institute, which it will be remembered was established in memory of Sir Henry Hawkins' famous dog, "Jack," primarily with the object of providing the poor with gratuitous treatment for their animals, propose holding a competition with the object of showing improvements in the Röntgen X rays, as applied to the diagnosis of lameness and disease in the human subject or the lower animals. Owing to the unfortunate illness of Professor Atkinson, the well-known bone-setter, who has charge of the Exhibition, it is perforce postponed, but probably, before long, what cannot fail to be an interesting collection will be shown at the institute in Kinnerton-street, where at present Professor Matthews, the medical superintendent, has a number of animal patients under treatment.

NOVAK and Sulc have examined nearly three hundred substances on the absorption of the Röntgen rays by chemical compounds. Their method of investigation consisted in attaching rings of glass to a sheet of paper, and placing uniform layers of the finely pulverised materials in the different rings, so that the thickness of the layer was 0·4 cm. in each case. The paper with the rings was then placed over a photographic plate, which was enveloped in black paper, and exposed to the Röntgen rays for a period of twenty to twenty-five minutes. By comparing the photographic effect of the rays where the substances were interposed, the relative absorptions were determined. The authors found, says the *American Journal of Science*, that a great number of organic compounds containing only carbon, hydrogen, oxygen, and nitrogen, are equably penetrable, and hence they conclude that the absorption has no relation to molecular weight or the arrangement of the atoms. Organic halogen derivatives were found to possess much greater absorption, which increased with the number of halogen atoms present. This effect increased with the atomic weights of the halogens, two atoms of bromine having a greater effect than six chlorine atoms, while iodine derivatives were entirely impenetrable under the conditions used in the experiments. This indication of the influence of elements of varying atomic weight led the authors to examine a series of elementary substances, all of rather low atomic weights.

ALUMINIUM GLASS.—M. Leon Appert, the distinguished glass expert, has contributed to the *Moniteur de la Céramique et de la Verrerie* an able article, in which he discusses the prominent part which, he thinks, alumina is destined to play in the manufacture of glass. "After having made numerous analytical tests of ancient window glass," says M. Appert, "I have arrived at the following conclusions, which appear to be of practical industrial value. The introduction of alumina into glass prevents, or at least retards, devitrification, which will occur always by the slow and repeated lowering of the temperature. The presence of alumina makes it possible that a part of the alkaline bases, soda or potash, may be replaced advantageously by an equal quantity of lime. Glass thus modified in its composition is more solid, less changeable, and more elastic. The alumina can be added to the silica without any inconvenience in a proportion not exceeding seven to eight per cent. The fusibility of glass is slightly increased thereby, while its ductility is not sensibly diminished. The only inconvenience that can arise from the use of aluminium is that it will colour the glass to some extent. This colouring does not result from the alumina itself, but from the action of the iron oxide, which is always found in it when in an impure condition. To sum up, the use of alumina, which permits its introduction only into bottle glass containing larger proportions of sand bases, should be extended equally to glass destined for other purposes, such as mirror glass, window glass, and especially drinking glasses. The quality of such glass would be greatly improved thereby. In the latter case the addition of alumina could best be accomplished if pure clay or, still better, if feldspar is used, which can be obtained at a low price. For the batch, the purest materials possible should be selected among those destined to furnish the silica, soda, and lime bases."

AT the annual general meeting of the Victoria Institute, Sir George G. Stokes gave an address on the Röntgen rays, and described at considerable length the work which led up to Röntgen's discovery. Referring to the fact noticed by Lenard, that the cathode rays could pass through aluminium, he said he did not think they did so in a manner analogous to the passage of light through glass. Supposing the cathode rays to be, strictly speaking, not rays, but streams of molecules, he suggested that an electrical action took place through the aluminium, resembling what electrolysis was on one theory supposed to be. The molecules, being highly charged with electricity, might set in motion, on the other side of the aluminium wall, other molecules similarly charged. Sir George Stokes then proceeded to discuss the nature of the Röntgen rays. They had their origin in the part of a Crookes' tube opposite the cathode; but they were not cathode rays. That they could pass through substances opaque to ordinary light did not prove they were not of the same nature as light. Light was regarded as consisting of transversal vibrations propagated in the luminiferous ether. Supposing X rays to consist of a process in the ether, were the vibrations giving rise to them transversal or longitudinal? They differed from ordinary light in several ways; but, if phenomena of polarisation could be obtained from them, that would prove them to consist of transversal vibrations. Many experiments had been made to get such phenomena, but most had failed. One or two investigators thought they had been successful. If that were so, we might affirm that the X rays were due to transversal vibrations of the luminiferous ether. The absence of diffraction and interference phenomena was explicable on the supposition that the vibrations were of an exceedingly high order of frequency. Lord Kelvin, in proposing a vote of thanks, said he had listened with satisfaction and comfort to Sir George Stokes, and his faith had been strengthened by what he had heard. Sir George declared for transversal vibrations, and he himself felt fortified in accepting that view. Not, however, that the fact was absolutely demonstrated, but there was great probability of that conclusion that was true.

AMONG the many phenomena for which the broiling sun of July is probably answerable, that of presenting the Röntgen rays in a new and somewhat grotesque light is one of the most curious in certain of its consequences. A number of eminent *savants*, French and American, says the *Daily Telegraph*, maintain that the X rays possess various mysterious virtues, such as that of killing microbes in the blood in the lungs, &c., and MM. Lorney and Genoud lately communicated to the Académie des Sciences the results of certain of their numerous and successful experiments, tending to show that even tuberculosis is mitigated and arrested by their influence—a statement which is categorically denied by an Italian bacteriologist, Sormani, who subjected no less than sixteen varieties of bacteria to the action of the rays, and discovered that the microscopical little scourges merely basked in them. Another enterprising Frenchman, from Dijon, having read that Professor Vanderbilt, of Tennessee, is of opinion that the X rays, if caused to penetrate the human skull, utterly destroy the roots of the hair, making havoc of the most luxuriant tresses, and leave the patient bald for life, hurried to Paris to make a fortune by applying the discovery. Not, of course, that M. Gaudoin was simple enough to fancy that the population would crowd to his ante-chamber and pay him royally for inducing baldness. Nature has provided numberless cheap ways of attaining that particular result. But he was aware that a considerable proportion of his countrywomen are, if not precisely born into the world, at least early endowed, with soft, silky moustaches, which, although eagerly yearned for by the masculine youth, are by no means appreciated by marriageable young girls, or even married ladies. He resolved, therefore, to use the Röntgen rays as a *dépilatoire*, to remove the superfluous hair from their lips, and, when needful, from their chins. Having discreetly made known his benevolent intention, he was not long in getting fair customers. They flocked into his laboratory, patiently awaited their turn, cheerfully paid their fees, and received the invisible rays on their full-blown moustaches and incipient beards But these hirsute appendages made no sign of vanishing, and one young lady who had been under the treatment asked to have her money back. Another lady, a well-developed widow from the Halles, whose moustache and beard ought to make her fortune at country fairs, told the operator that, if he had not found an infallible *dépilatoire*, she had, and, pointing to her fingers and nails, informed the scared scientist that she would operate on the exiguous hairs of his devoted head unless he then and there refunded the money. M. Gaudoin appeased these infuriated Graces, and hurriedly retired from the business with the fees he had accumulated.

THE BRITISH GUIANA GRAPHIC CLUB —Elsewhere in our columns we print a letter from an old friend of the JOURNAL, Mr. H. H. Cunningham, President of the British Guiana Graphic Club, also a paper by one of the members. We append some interesting extracts from the local press relating to a recent Exhibition of the Club: "THE GRAPHIC CLUB.—The members of the above Club are at present holding an Exhibition in their studio in Main-street, where the artistic productions of the members, comprising photographs and paintings, are on view. There are three classes of pictures—landscape, portraits, and paintings. In the two former, Mr. Anson, of Morawhanna, has some conspicuously good platinotype photographs of typical scenes in the interior. The groups of aboriginal Indians are exceptionally fine, and his picture of the Barima Mine conveys a vivid impression of the famous property on which the immediate future of the gold industry in this colony will so much depend. Mrs. Fred. White exhibits some photographs which fully maintain the reputation she has won as a distinguished lady amateur, and her study representing two little boys fishing in a trench, where the Victoria Regia is growing in profuse luxuriance, is one of the most effective things of the kind we have seen. The members are quite up to date, and on the walls are hung photographs of the latest spectacular sights that the city has afforded, including the swearing-in of Sir Augustus Hemming, and the fire at Messrs. Sandbach, Parker, & Co.'s premises. Mr. F. A. Conyers exhibits some very fine impressions, notably a graphic scene taken from the Botanical Gardens, entitled, *When Shades of Evening Fall*. Mr. H. H. Cunningham (the President) exhibits an oil painting of Kaieteur Fall, and Mrs. Bellairs and Mrs. George Garnett have also some pretty studies in oil. . . . . In connexion with the Exhibition of the Graphic Club, to which allusion is made elsewhere, the Chairman and members held an "At Home" on Saturday evening. A large number of invited guests, which included His Excellency the Governor, took advantage of the opportunity thus afforded them to view the Exhibition, which evoked general expressions of admiration. Many, too, were not a little surprised to learn that such a strong amateur organization exists in the city, with members capable of turning out such excellent and highly finished work. A ballot was held during the evening, and as the result of it the following artists were awarded the palm:—Class A, Views, Mrs. F. White (for the picture of two boys fishing in a city trench); Class B, Portraits, Mrs. F. White (portrait of a little girl); Class D, Paintings, Mr. H. H. Cunningham (the Kaieteur Fall). We trust this Exhibition will be the means of inducing many others, who either paint or go in for amateur photography, to join the Club."—*Demerara Daily Chronicle.*

Patent News.

The following applications for Patents were made between July 15 and July 22, 1896:—

X Rays.—No. 15,554. "Improvements in and relating to Apparatus for the Application of the Röntgen X Rays to Human Beings, Horses, and other Animals." V. E. Johnson.

Screen Kinetoscopy.—No. 15,603. "Improvements in or relating to Apparatus for Use in Taking or Reproducing Animated Pictures." H. J. Heinze.

Printing Machinery.—No. 15,781. "Improvements in Photo-printing Machinery." Complete specification. L. M. Schmiers and J. D. H. Stein.

Lantern Tinters.—No. 15,804. "Improvements in the Method of Producing Coloured Glass Lights for Lenses, also applicable for other suitable purposes." J. Davis and A. J. Davis.

Developing.—No. 15,847. "Improvements in Apparatus for Developing Photographic Plates." W. Brookes.

Printing.—No. 15,852. "Improvements in Chemical Compositions for Preparing the Surface of Suitable Material for Photographic Prints." E. P. Schoenfelder and E. Kehlf.

Developing.—No. 15,929. "Improved Apparatus for Developing Photographic Films in Rolls." A. M. Thompson and W. W. G. Webb.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

August.	Name of Society.	Subject.
3	Borough Polytechnic	Excursion: St. Albans.
3	Croydon Microscopical	Excursion: Chilworth.
3	North Middlesex	Exc.: Cambridge. Leader, H. Walker.
3	South London	Exc.: Eynsford. Leader, H. Goodwin.
5	Borough Polytechnic	Open Evening.
5	Photographic Club	The Use of Small Cameras, and the Making of Enlarged Negatives.
8	Borough Polytechnic	Excursion: Neasden and Harrow.
8	Croydon Microscopical	Conversational Meeting.
8	Gospel Oak	Excursion: Richmond.
8	Hackney	Excursion: Holland Park Gardens or Penner Wood. Leader, J. Gardner.
8	Oldham	Excursion: Moreton Hall. Leader, W. A. Nash.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

July 23,—Mr. A. Haddon in the chair.

Wellington's Negative Paper.

Mr. J. E. Hodd passed round a negative and a print from the same, taken on Wellington & Ward's new negative paper, which was to be distinguished from their stripping film, as the emulsion with which it was coated was not removed from the paper support after development, but the printing done through the paper. It was not intended that the negative should be waxed for printing, and, in fact, he found that course objectionable. It was easy to work, and printed in about the same time as a glass negative. He had found no trace of halation, but said there was a tendency to blister. He mentioned that he had used no alum.

Mr. Kellow pointed out that alum was recommended by the makers, and would probably do away with the blistering.

The Hon. Secretary understood that Mr. Wellington advocated a very short exposure of the back of the paper to light, so as to obviate any grain in the negative by filling up, so to speak, the small inequalities in the paper. He considered that for carbon printing the trouble of making reversed negatives was overcome, as one could print from either side.

Mr. A. L. Henderson read a paper entitled

What is it?

[see p. 490].

The Hon. Secretary recently used some slides, which he had possessed for about seven years, with some very rapid plates. Two of them, developed soon after exposure, came out quite correct, but the others, which had been left for four days before development, exhibited a band across each near the position of the hinge, although not very marked.

Mr. Hodd gave some further experiences he had had with his dark slides in the presence of their maker, and, although the plates had never seen daylight, the band still appeared. He showed some of the hinge material and the black varnish, which was composed of gold size and dead black.

The Chairman remarked that turpentine would repel the developer and prevent its action, but, if dissolved off with ether and the plate washed, the developer would be able to effect its object.

Mr. Welford said years ago he had subjected a dark slide to very hard treatment by putting it into a damp cellar for a time, and then inserting a plate, and exposing to the sun's rays until the moisture had condensed on the plate, but was unable to trace anything to this treatment.

The Chairman detailed some experiments which had been made, showing the persistence of the action of the X rays. A number of articles were placed on a card box, in which was a sensitive plate, and an exposure made. Subsequently another plate, treated in the same box, but without the objects, showed, on development, reproductions of these objects, which had been removed, and which was due, he believed, to some constituent of the cardboard.

PHOTOGRAPHIC CLUB.

July 22.—Mr. Frank Haes in the chair.

Mr. Welford passed round a copy of the *St. Louis and Canadian Photographer*. This photographic journal is illustrated with a series of sixteen pictures, showing the ruin inflicted upon the city of St. Louis by the tornado which struck the city. Mr. Welford also passed round a considerable number of snap-shots of the Convention. The negatives were developed and prints made in forty-eight hours.

Mr. Wallis showed some Daguerreotype plates, the tarnished surface of which he had endeavoured to repolish. Failing in this, he had replated them, but the result was not successful, the metal being, apparently, too thin to stand the burnishing of the silver deposit.

Brixton and Clapham Camera Club.—A meeting was held on the 21st inst., the greater part of the time being occupied in examination of the prints sent in for the recent quarterly competition, and a study of the criticisms which the Judge (Mr. Horsley Hinton) had been requested to make. The bronze medal, presented by the President, was won by Mr. F. W. Levett, Mr. J. Gunston being second, and Mr. G. W. Welham third.

North Middlesex Photographic Society.—July 20, Monthly Instruction Evening, Mr. Smith in the chair.—Mr. S. E. Wall gave a demonstration on

Bromide Printing.

Speaking of the kind of paper to use, he preferred rapid paper when artificial light is to be used, and slow for daylight. He found it an advantage, when enlarging by daylight, if the light was very bright, to tone it down by means of several sheets of tissue paper placed between the light and the negative, until a Watkins' exposure meter took about 100 seconds to turn to the standard tint. He advocated the free use of matt varnish and judicious pencilling on the negative to get the best effects. If the negative was at all weak, use a weak light, and a good light for a strong negative. He found Eastman's rapid paper registered about 35, Watkins' and Wellington's about 30. He liked rough bromide paper, but found it more liable to blister than smooth. He thought there was more latitude in exposure in bromide paper than in a dry plate, and ferrous oxalate was better to use than hydroquinone, and less liable to fog, and a mixture of old and new developer gave better results and was more under control. Hypo 1·200 was a good accelerator, but wanted careful using. Too much bromide gave a nasty greenish tone. The paper should be carefully washed after the acid bath before fixing, and, if hydroquinone had been used, the addition of bisulphite of soda to fixing bath got rid of any stain. He passed round some fine examples of his work, and then developed two prints, keeping back certain portions by partially drying with a spill of blotting-paper, and using a small quantity of developer. After replying to several questions, a hearty vote of thanks was accorded to the lecturer.

July 27, Mr. Marchant in the chair.—Mr. J. T. Sandell read a paper on

Anti-halation and Latitude in Dry Plates.

He sketched the various methods used to combat the evil of halation, and contended that the best method of overcoming it was by means of multiple films, as found in Sandell plates. These plates reduced the simplicity of development to a minimum. All that was necessary was to immerse the plate in the developer (several, having different exposures, could be developed in one dish) for a certain time, according to the strength of the developer; take out and fix. If any were too dense, they could be reduced with potass ferridcyanide. He developed three plates together in a dish, an interior, fifteen minutes exposure, and a landscape, one having one second and the other sixteen seconds. He passed round some magnificent prints taken from Sandell plates. In reply to a question, he said a yellow screen could be used with benefit with exposure three or four times that given with isochromatic plates.

Stockton Photographic Society.—At the monthly meeting, held at the Royal Hotel, on the 21st inst., the chief incident was a presentation to the Hon. Secretary (Mr. J. E. Ellam), who is leaving the district. The gift consisted of a silver cigarette case bearing the inscription, "Presented to Mr. J. E. Ellam by the Stockton Photographic Society, 21st July, 1896," and a silver-mounted walking-stick. The President (Mr. W. S. Fothergill), in handing them to Mr. Ellam, said that he hoped they would in after-time serve to remind him of his old friends in Stockton. A letter was read from Dr. Stainthorpe, of Saltburn, regretting his inability to be present, and expressing his sense of the loss to the Society which Mr. Ellam's removal would cause. Eulogistic speeches expressing admiration for Mr. Ellam's skill and gratitude for his help—which were ever at the disposal of members both in the way of demonstrations before the Society and advice in cases of individual perplexity—were made by the following gentlemen: Messrs. W. Downs (Vice-President), J. H. Jackson, F. L. Dodds, M.A., Thomas Watson, M.D., H. Bradley, G. F. Allan, and J. Bowron. Mr. Ellam thanked the members for their present, assuring them that, while nothing of the sort was necessary to keep him in mind of his long and pleasant association with the Stockton Society, he greatly appreciated this mark of their esteem. He further promised a demonstration of carbon printing for the next meeting if he should be within reach. Regret was expressed that Mr. H. Bradley (a Vice-President) is also about to leave, and a hearty farewell was bidden to both members.

Correspondence.

☛ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

TRAILL TAYLOR MEMORIAL.

To the EDITORS.

GENTLEMEN,—As the time for closing this fund is now at hand, I shall feel obliged if you will allow me, through your columns, to ask those who have not already subscribed, and who intend to do so, to send me their subscriptions at once; and, further, may I ask that Hon. Secretaries of societies, and others who have subscription lists open, will, at their earliest convenience, let me know the amounts they have in hand so that I may be enabled to report to the Executive Committee, with some degree of accuracy, the total sum to be dealt with.

Your readers will already have learnt, from your report of the Photographic Convention, that that body, at their annual meeting, voted twenty guineas to the fund.—I am, yours, &c., ALEXANDER MACKIE,

3, *Upper Baker-street, N.W.* *Hon. Secretary to the Fund.*

ORTHOCHROMATIC PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—On looking over Mr. Bothamley's Convention paper on Orthochromatic Photography, as given in the last week's issue, I find therein some criticisms referring to a communication of mine upon the same subject.

Mr. Bothamley states that the main conclusions from my experiments are vitiated by the fundamental error of adding a much larger quantity of dye to the emulsion than would enter into intimate association with it. He also states, without any modification, that the method adopted was to add a definite quantity of dye to a definite quantity of emulsion.

This is true only for a limited number of the dyes used.

I always tried to avoid the optical, as distinguished from the chemical, method of sensitising, and only resorted to the former when I found the latter impossible. In a chemically sensitised emulsion I maintain that the dye compound of silver and the bromide of silver are as closely associated as in an ordinary chloro-bromide emulsion, no matter the relative proportion of silver dye compound and silver haloid or haloids.

Regarding Mr. Bothamley's remark with reference to the extremely small quantity of dye required to produce "maximum sensitising effect," I would prefer to say "maximum general sensitising effect," for the maximum sensitising effect of a dye can be increased by adding a larger quantity of the dye, and this latter method I have frequently had to employ so as to get results that I could interpret photographically. I do not therefore agree with Mr. Bothamley when he says that the quantity of dye added was much larger than could enter into intimate association with the silver bromide. The quantity may be large or small within certain limits, and yet always associated with silver bromide if the emulsion be properly prepared.

In the near future I propose giving a further communication on this subject, and hope to prove conclusively that the position of maximum photographic effect of a dye is somewhat nearer the red end of the spectrum than its maximum absorption.—I am, yours, &c.,

Cricklewood, N.W., July 27, 1896. J. J. ACWORTH.

PHOTOGRAPHY IN BRITISH GUIANA.

To the EDITORS.

GENTLEMEN,—You used to know me in your pages, and I still read them; but, since residence in the tropics, I have been able to do little for photography except locally.

The amateurs here are gathered under a club, called the Graphic Club of British Guiana, which, though it includes some who paint and model, is mainly confined to photographic amateurs. Our title, as you will see, includes all sorts of "graphing." We number some thirty or forty members, and meet monthly for the hearing of papers on subjects of local and photographic interest, and for discussion (much as English societies do), in our own premises in Main-street, Georgetown, where we have a dark room and studio.

I send you a paper lately read by Mr. Perkins, F.R.G.S, one of the members who was the first to climb, along with Mr. Everard Im-Thurn, that strange mountain, on the borders of British Guiana and Brazil, called Roraima. It has been lately climbed again by Mr. Quelch and Mr. F. M'Connell; and they, by passing a night on the top, were able to secure better photographic and other records of its peculiarities.

Photography in this damp climate, with a temperature of 80° to 90° Fahr., is quite another thing from photography in England, and one's trials are many—bacterial growths attack, and render worthless, plates in a fortnight, and consequently dealers can't keep more than a small stock; thus one is often at a loss for a plate, and when a good subject occurs lose it. Nor does printing paper keep any better, and I leave you to judge of platinotype. Still, we do our best, though sulphurous language gives a tone now and then.—Yours, &c.,

H. H. CUNNINGHAM, J.P., B.A.

Georgetown, British Guiana, July 7, 1896.

ART *versus* MECHANICAL PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—At a time when so many are complaining that photography is being thrust on one side by cycling, and that the ranks of the latter are increasing at the expense of the former, it will not be amiss to ask the question, Have we more than a mere handful of men and women occupying themselves seriously with the subject, and going beyond the mechanical manipulations, which are at the best only a means towards the end, the expression of art through the medium of the camera? I have come to the conclusion that the number of those possessing more than a mere transient interest in photography is very small indeed; for, considering either the societies, the exhibitions, or the journals, everywhere, excepting in a few rare instances, one finds the eternal supremacy of matters relating to the advantages of different forms of apparatus, the merits of rival processes, the trivial details of manipulation, and but rarely those relating to the principles of art, the education of the eye, and the cultivation of artistic qualities. In this manner do we occupy ourselves, for ever worrying about the paints and brushes, or the canvas, while the Goddess of Art is sleeping on our doorsteps, waiting to be let in.

The time is ripe for a great development of pictorial art in photography, if only photographers will arouse themselves and become alive to its possibilities. There is a need for good teachers of photographic art; we have ample means of learning the rudiments of manipulation. Cannot the Linked Ring, our only organization which has grasped the artistic potentialities of photography, arrange for a course of lectures in London and the provinces? They have put an ideal before us, will they now help us towards attaining it?—I am, yours, &c., MATTHEW SURFACE.

Bradford, July 24, 1896.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:—

John Lander, 24, Division-street, Sheffield.—*Two photographs of gun shield.*

John Lander, 24 to 30 Division-street, Sheffield.—*Photograph of tied steel test. Photograph of spiral steel test.*

ADDRESS WANTED.—NORMAN VINE. We do not know the address, but he is a Leeds man, and probably Mr. Godfrey Bingley, Thorniehurst, Headingley, will tell you where he lives.

PLATINOTYPE.—HANTS. With paper the colour of that sent it will be quite useless to attempt to get prints with anything like pure whites. It has clearly been exposed to damp, as the makers say.

ROYAL ARMS.—DOUBTFUL. Supplying photographs to the Royal family under the conditions mentioned certainly does not entitle you to put up the royal arms. To use them you must obtain the Royal Warrant to do so.

LENS.—C. WELLS. The lens, as the prints show, is a very good one; but you are expecting too much from it. A lens of four and a half inches' focus will not cover a quarter-plate sharp up to the corners with its full opening of *f*·5·6.

PHOTOGRAPHING HYMNS.—G. S. says: "Will you tell me if permission is required to photograph hymns for magic-lantern slides—*Hymns Ancient and Modern* and Moody and Sankey's?"—In reply: Yes, if the hymns are copyright.

PHOTOGRAPHING IN HYDE PARK.—HARD UP. You will certainly not get permission to take either ferrotypes or glass positives of the equestrians in the "Row." Itinerant photography is not allowed in Hyde Park, or, indeed, in any of the royal parks.

STAINS ON NEGATIVE.—OXON. The stain on the negative enclosed is caused by imperfect fixation—that is, the whole of the unaltered bromide has not been dissolved out. As the negative has been printed from several times, nothing can now be done with it to remove the stain.

STUDIO.—M. CARPENTER. Either fix on 1 or 3 form of studio in preference to any of the others for general all-round work. If you are likely to do many groups from time to time, the latter form might prove rather the better of the two, but so little as not really to be worth much consideration.

FRILLING.—T. SHEANN. This is simply a hot-weather trouble, though we have never suffered from it with the brand of plates referred to; but we are careful not to handle them with warm fingers more than we can help, as all plates are liable to frill more or less with such treatment in such weather as we have been having of late.

METHYLATED SPIRIT.—A. C. V. In all probability the seller has not deceived you. It does not follow, because the spirit is rendered turbid on the addition of water, that it is "finish." All the methylated spirit now sold retail at oil shops becomes turbid if mixed with water, owing to the compulsory admixture of mineral oil with it.

LEARNER AND HOLIDAYS.—S. WEEDON.—If you made no arrangement, when the agreement was signed, as to holidays, you are not entitled to any; but most employers give their hands a week or so during the year. Probably yours may do so; but, of course, it must not be expected at his busiest season, and that seems to be what you are complaining of.

COLLODION PROCESS.—THOS. COLLINS. The formulæ for collodion, as given in the ALMANAC, are quite right. Probably your failure is due to your not keeping strictly to temperature and time, imperative conditions in the manufacture of pyroxyline. Why not purchase your collodion ready-made, that is what nearly every photographer did, and does now?

CRACKED PRINTS.—S. RICHARDS. The prints are, as you say, in a sorry plight, but their state is not at all unusual with some of the very highly albumenised paper, if the prints are allowed to dry *and curl up* this hot weather. Prints on that kind of paper should be dried between blotting boards, so that they are kept flat the while, or be mounted while they are wet. In either case there will be no cracking.

CARBON PRINTING.—W. S. READ. Your difficulty is distinctly traceable to the hot weather. The water in which the prints were soaked in prior to mounting them, the support upon which they were developed, were too warm. This water should not exceed 65°, or trouble may be expected. Water at this temperature is not difficult to obtain, as a rule. If it is in your case, a few lumps of ice will supply all that is necessary.

POISONS ACT.—PROVINCIAL PHOTO-DEALER. No, you will be acting illegally if you sell solutions for intensifying negatives which contain either bichloride of mercury or cyanide of potassium. That Trade Union, the Pharmaceutical Society, will be down upon you for their penalty. It is only members of their body that the law allows such things to be vended by, although they, as a rule, know nothing of their uses or their properties.

RED PRINTS.—A. S. B. writes: "Would you please to favour me with the formula of the toning bath, also what paper is used to produce prints similar in tone to the colour of the printing on the enclosed tissue? I have seen prints similar to this (but, if any difference, not quite so red), and like them very much, and should like if you could favour me with the information."—The prints so much liked are, doubtless, by the carbon process, and the tissue used is what is known as "red chalk tissue."

STARCH PASTE.—P. Z. L. S. asks: "Can you tell me what I can put in my starch for mounting prints to prevent it from turning sour, and at the same time have no injurious effects on the photographs?"—Carbolic acid or salicylic acid will prevent the starch from going sour; but we do not recommend any antiseptic to be used, as starch is so cheap and the paste so quickly prepared. Freshly made starch is more adhesive and better for silver prints than stale starch made containing foreign matter.

ENAMELLING SILVER PRINTS.—A. B. says "he would like to know if there is any method of making collodion to enamel silver prints cheaper than using the ordinary enamelling collodion and thinning solution, or whether vitriol can be used in part?"—"Vitriol" certainly cannot be used in place of either the ether or the alcohol. There are no cheaper solvents for the pyroxyline than methylated ether and alcohol. The latter may be the methylated if it is free from the mineral spirit, and of not greater specific gravity than ·820.

EXPOSURE.—S. A. JONES. To take a group of a couple of hundred people in a "fairly lighted" hall is not an easy matter. We can give you no idea what would be a proper exposure, although you tell us the lens and stop, and the plates to be used. "Fairly lighted" at six in the evening is too vague. What we should recommend you to do is to make one or two exposures in the hall a day or two beforehand under the same conditions as the picture has to be taken. Then you will be in no doubt as to the exposure required.

RESIDUES.—RESIDUE says: "1. I save all fixing baths from plates in an earthenware jar. Can I throw the silver down with hydrochloric acid, or what would be the easiest way to collect the residue ready for the crucible? 2. I also save the first washing of prints—P.O.P.—and put this in with the above old fixing bath. Is this all right?"—In reply: 1. It is better to precipitate the silver from old fixing baths with sulphide of potassium (liver of sulphur). 2. It is preferable to keep the washing waters separate, and throw down the silver from them with hydrochloric acid or common salt.

FADING PRINTS.—HERTS AMATEUR says: "I sent some negatives to a professional printer about a year ago to be printed on gelatine paper. At first he demurred to doing them on that, and recommended me to have them on albumen instead. However, I insisted on their being on gelatine, as I preferred it, and got them. Now many of them are turning yellow, and, on complaining, he says he is not surprised, and that I should have had them on albumen, as he recommended, and he will make no recompense. What can I do?"—The only thing we can suggest is to sue for the amount paid, and produce expert evidence that the yellowness is due to his work, and not to the process—a somewhat difficult matter.

EXPIRATION OF LEASE AND REPAIRS.—R. C. W. Without seeing the lease, we can give no definite opinion; but if there is a clause in it, and most probably there is, as in most leases, that the premises are to be left in good repair, the tenant will have to put them in good repair. That the landlord has not troubled about the condition of the premises during the fourteen years till now is of no moment, and no defence to not leaving them in good repair at the end of the term. That must be done if it is in the terms of the lease to do so.

INKY TONES IN BROMIDE ENLARGEMENTS.—W. SEARLE writes: "I enclose some pieces of bromide enlargements to show you the cold, inky-like tones I frequently get. I use the iron developer recommended by the makers of the paper. Sometimes I get very satisfactory colours, but more generally such as these, and all with the same developer, for I use no other. Is it likely that the paper is mixed?"—Very unlikely indeed. The difference in colour is entirely due to the exposure. The examples enclosed are all under-exposed, and have been forced in development, hence the cold tones. The others, the colour of which was good, doubtless, received a proper exposure.

REPAIRING LEASE.—R. W.—So far as we can see, your landlord is quite right in his claim, though we can give no opinion as to whether the amount is reasonable or not. In taking the premises, you signed the lease, for seven years, agreeing to paint the outside of the premises once during the term, and the inside twice. It seems that you have only fulfilled your part of the contract once with regard to the inside, and not at all as to the outside. This will now have to be done, although you will reap no benefit therefrom. Had it been done before, you, of course, would. You will also have to make good all dilapidations as well. We should advise you to come to terms with the landlord, for if you do not, and he appeals to the law, you will be certain to be the loser.

DESIGN FOR STUDIO.—STUDIO writes: "I beg to enclose a plan of a studio I propose building shortly. I would be very much obliged if you will give me your opinion on it, and also answers to the following:—1. Is the slope of roof sufficiently steep? I have extended the roof one foot, as you will see by the plan, to shade the roof (glass) from sun, as studio cannot be shaded on south side. It will face north, with house on east end. 2. What material is best for blinds in studio, and best colour?"—1. The design is very good, and the only suggestion we can make is that the roof might be extended a little more on the south side, so as to shield off the sun more at midsummer. But that is not really necessary, as it would only be advantageous for a month or two in the year. The slope of the roof will do quite well. 2. A light green or dark blue window holland will be very suitable for blinds.

STEREOSCOPIC PHOTOGRAPHY.—AD VALOREM writes: "I shall be greatly obliged if you will give me information as to the *pros* and *cons.* of taking stereoscopic pictures by (1) twin lenses, (2) by mirror appliances. Will they (1) and (2) give equivalent results, &c.? I think a short article on the above subject would be appreciated by a number of the JOURNAL'S readers who have a lot of doubts on the principles involved."—In reply: We shall probably have an article on the subject shortly. In the mean while we may say generally, that, the employment of the double reflection principle in stereography obviates the cutting or transposition of the prints—gives you, as it were, a direct stereoscopic result, the effect of which is practically as good as that obtained by twin lenses and transposition; but the binocular method has advantages which make it *par excellence* the best system of taking stereo-photographs.

TONING.—E. BATT says: "I shall esteem it a favour if you could oblige me by letting me know what formulæ I should use to obtain a good purple-black, or, what I mean, next door to over-toning? I have tried the ordinary sulphocyanide and gold bath, and sometimes obtain the above colour in this bath, but, on immersing in the hypo, the prints change to a brown, although, when dry, they are a shade better, and dark, but not much. Should you advise the combined bath, and tone till I get the colour, or can you put me up to a trick so as I shall be able to obtain always the one colour—a blue-black? Also, if you could suggest my purchasing any particular book that would give me a few hints on toning, I shall be thankful. It seems to be my great misfortune, 'toning;' everything else seems to go quite correct and smoothly."—In reply: 1. Possibly the phosphate bath will give the tone you want. The formula is: Gold chloride, 1 grain; phosphate of soda, 20 grains; water, 8 ounces. It gives tones of a deep purple nature, but must be used soon after preparation. We have used this successfully ourselves. 2. We do not recommend the combined bath. 3. We know of no book specially devoted to the purpose, but Abney's *Instructions* may help you.

THE X RAYS.—DR. G. LINDSAY JOHNSON writes: "I notice in this week's (July 24) number of THE BRITISH JOURNAL OF PHOTOGRAPHY, under Answers to Correspondents, you state: 'The Röntgen Rays and Consumption.—H. R. Sharples. Your doctor was quite right; the X rays are not germicidal.' I think your reply is certainly at variance with my experience. I enclose a cutting from this week's *British Medical Journal* which fully bears out my results."—In reply: We were aware of Lortet and Genoud's experiments with inoculated guinea pigs, but we believe we are correct in stating that the preponderance of medical opinion so far is opposed to the X rays having any germicidal effects—that is, for curative purposes. Dr. Lindsay Johnson will probably be interested in the following extract from the *Daily Chronicle* of Monday last: "We referred last week to some experiments made to test the action of the Röntgen rays on tuberculosis. M. F. Berton has recorded before the Academy of Sciences some trials of the effects of the rays on the diphtheric bacillus, unfortunately without favourable results, as no attenuation of the virus could be obtained by exposure to the rays for forty-eight hours." We shall, however, be glad to know definitely that Dr. Lindsay Johnson's own experiments have been successful.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1892. Vol. XLIII.—AUGUST 7, 1896.

Contents.

EX CATHEDRÂ.

Photography, in the person of Mr. W. Downey, of the well-known firm of W. & D. Downey, was highly honoured on the occasion of the festivities held in connexion with the marriage of Princess Maud of Wales. Mr. Downey received an invitation to the royal garden party, and Her Royal Highness the Princess of Wales sent him a written permission to privately inspect Princess Maud's presents. This recognition of photography at one of Royalty's most important functions will, we are sure, be much appreciated throughout the profession. It adds another to the many marks of encouragement and support that photography has received from the members of the reigning House.

* * *

Messrs. Elliott & Son, of Barnet, inform us that their new factory for the manufacture of photographic papers is now complete. They have already coated over a mile of "Barnet" platino-matt bromide paper in it. The building is seventy feet in length, and, as a precaution against fire, is quite isolated from the dry-plate factory. The new machinery is a great improvement on the old, and the same may be said of the ventilating and drying arrangements. The new factory is believed to be the most perfectly fitted of its kind.

The Annual Meeting of the Photographic Copyright Union will take place on Thursday, October 8 next. The date has been chosen in order to give country members who may be in London at that time for the purpose of inspecting the Photographic Society's Exhibition an opportunity of also being present at the Copyright Union meeting. Last year a great deal of useful work in connexion with the revision of the rules and other important matters was got through at the annual meeting. The attendance was large, and much interest was manifested in the proceedings. We anticipate that this year's meeting will excite equal, if not greater, interest among photographers.

* * *

The value of photographs as evidence was never more strikingly illustrated than in the following case, which we quote from an American contemporary, relating to the hearing of the Senate Investigating Committee at Philadelphia on June 26, which was enlivened by the introduction of the Citizen Municipal Association, of a series of instantaneous photographs, in their efforts to show the interference by the police at the municipal election in February last. During the course of the hearing, Charles W. Crane, of Trenton, a photographer, was asked to identify eight large photographs representing scenes on election day, last February, outside the polling place of the sixteenth division of the fifth ward. The views showed policemen standing on the steps of the polling booths and talking through an open window to persons inside. Mr. Crane said that before seven o'clock in the morning he took his station at a second-floor window of a house just across the street, and he took the photographs at intervals during the day without any one in the street being aware of his presence.

* * *

It is not reported what effect the production of these photographs had upon the Investigating Committee, but it appears that many other similar photographs were identified; indeed, the police were systematically shadowed by means of the camera. Happily, on this side of the Atlantic, occasion rarely arises for the employment of photography to prove interference with the rights of citizens.

* * *

It is probable that ere long more than one "substitute" for celluloid as a support for the sensitive film will be placed on the market. With that end in view, we are aware of experi-

ments being conducted by three dry-plate makers with three different, if not wholly dissimilar, substances. A sample of one of these proposed substitutes was recently shown us by Mr. Conrad Beck, who tells us that it is to be employed for Frena films. In appearance and degree of flexibility this strongly resembled celluloid, although we were not informed of its composition. On the other hand, we were assured by a well-known film-maker that a perfect substitute for celluloid had yet to be produced. It is also open to doubt whether, except as regards cost and some few unfavourable experiences of the keeping qualities of celluloid films in hot climates, there exists a real necessity for the displacement of celluloid. The slowing of the emulsion, the destruction of the undeveloped image, and spontaneous fog in hot climates are faults that have been urged against celluloid films; but the evidence adduced has not been conclusive. As regards the keeping qualities of celluloid films under normal conditions at home, we seldom hear any objection urged. Recently we exposed and developed some celluloid films that were five years old, and their good qualities were unimpeachably good.

* * *

"Sitting for a Picture" is the title given to a series of hints, intended for those about to be photographed, that recently appeared in a contemporary. Our professional friends will, no doubt, be interested in the instructions, which probably did not emanate from a photographic studio, and to some of which it would be easy to take objection.

* * *

"A veil imparts a patchy appearance to the face. Gloves make the hands appear much larger than they are in reality. It is unwise to wear a new dress; it always falls in awkward folds. Whenever possible, it is money well spent to drive to the photographer's. A feather boa or a lace fichu has a wonderfully softening effect on the features. Generally speaking, the head and shoulders make a far prettier picture than a full-length portrait. Above all, if you want your sun picture to have a natural expression, you must forget where you are. Unless there is any urgent reason for it, it is a great mistake to be photographed if you are either out of health or in low spirits. A just-the-mode-of-the-moment style of costume or coiffure will 'date' the photograph, and soon make it look out of fashion. A white dress, or one that takes 'white,' gives a ghastly effect, and one far from becoming, unless the sitter is young and pretty."

* * *

The hints are clearly addressed to ladies, a fact which in itself justifies the assumption that they (the hints) are not likely to be attentively observed. Ladies, as a rule, pay little heed to photographic dictation in millinery matters.

ORTHOCHROMATIC PHOTOGRAPHY.

It is satisfactory to find that some of the leading supporters of the Photographic Convention have at last recognised that an annual gathering of this kind should, if possible, be made the occasion, as it was so aptly put by Mr. Bothamley, "to take stock, as it were, of the present position of our knowledge of particular branches of photography."

We should like to see the example thus set in the paper under the above title and in that of Mr. Haddon followed in years to come.

The two points directly raised by Mr. Bothamley are of considerable practical importance, and open up fields of investigation, which, however, are unfortunately beset with considerable difficulties. In the first place, there is considerable difficulty in obtaining pure samples of the dyes, for many of the commercial samples are loaded with impurities, either intentional or accidental. Further than that, it is well known that the haloid salts of silver differ considerably in their behaviour to various dyes, and therefore the experimentalist must either manufacture his own emulsion or else work with an unknown quantity in the shape of commercial plates.

With regard to the two hypotheses of the action of the dyes, the one that seems the more feasible, particularly in the face of Mr. Bothamley's experiment, is that held by Eder and Vogel. It is difficult, too, to accept the theory of the oxidation of the dye when we recall Eder's experiment, in which he added some eosine to a gelatino-bromide emulsion, and separated by a centrifugal machine, and washed the silver bromide three times in succession, till it showed no colouration, and yet gave a distinct sensitising maximum in the neighbourhood of the D line, which is so characteristic of it. Further than that, if the oxidation theory is correct, it would only be necessary to paint an unexposed dry plate with an oxidised dye to obtain a strong image. This experiment has actually been tried by Eder with negative results.

A solution of cyanine, which had been exposed for one year to light, and turned quite brown, and would therefore contain plenty of the oxidation products of cyanine, caused no reduction when painted on an unexposed plate and submitted to the action of a developer.

It may possibly be as well to call attention at this stage to a passage which occurs in Meldola's *Chemistry of Photography*, p. 320. After discussing the two hypotheses and explaining that the bleaching of a colouring matter may be due to photochemical oxidation, he goes on to say: "If this be the case, atmospheric oxygen may be essential for the production of orthochromatic effect, and the formation of a second maximum in the less refrangible part of the spectrum might be prevented by immersing the dyed plate in a reducing solution, or in some inert liquid or gas which prevented the access of air. Experiments of this kind might easily be made, and, if the action in the green, yellow, or orange, did not take place under these circumstances, the chemical hypothesis of orthochromatic photography would be raised to the rank of a proved theory; while, on the other hand, if the second maximum still appeared, this hypothesis would not be disproved, because it is possible that the breaking down of the complex molecule of the colouring matter by the action of light might take place in the absence of oxygen, and thus also give rise to the formation of products of a reducing character."

It is obvious from this that further researches upon the action of the oxidation products of the various sensitisers in the haloid salts of silver are required before we can obtain any satisfactory explanation of orthochromatic photography.

The second question, as to the coincidence of the maximum absorption with the maximum of sensitiveness, we do not intend to touch upon, except for the secondary point, and that is the screening effect of the dye used.

To attain the best results on colour-sensitive plates for all-round landscape work, it is generally admitted that a yellow screen is necessary, for the simple reason that, although we increase the sensitiveness of the silver salts to the less refrangible rays, yet the abnormally high blue and violet

sensitiveness still preponderates. Why, then, should we not insert our yellow screen in the plate itself, and do away with the usual glass light filter, and thus make use of the very screening effect to which reference was made?

The idea of replacing the yellow screen by dyeing the vehicle of the silver salt is due primarily, we believe, to Dr. E. Albert, who some seven or eight years ago placed upon the market an orthochromatic collodion, the sensitiser for which was ammoniacal solution of silver eoside, any excess of ammonia being neutralised with pieric acid, the ammonium picrate thus formed acting as a screen. This idea was also suggested some years later by Vidal for gelatine plates.

There may be, of course, considerable difficulty in finding a dye which, whilst efficient as a reducer for the blue and violet, shall sensitise for the green, yellow, and orange, and if we have to resort to two dyes—one as sensitiser, the other as screen—another difficulty of the incompatibility of the two may stare us in the face. Eosine, which is at present the best sensitiser for yellowish-green, would, if used of sufficient strength to dye the film, cut down the green rays, for the absorption curve of this colouring matter commences at $D\frac{1}{2}E$, rises sharply to a maximum at $D\frac{3}{4}E$, and then, slowly sinking, stretches beyond F. Now, at E. we find there is always a sudden depression in the sensitiveness curve of all orthochromatic plates, and therefore the screening action of eosine would make bad worse. The same statement applies equally to cyanine, for, with a strongly coloured film, there is practically no sensitising action at D, where, without any screening effect, practically the maximum sensitiveness should lie.

The argument may, of course, be advanced that this placing of the screen in the film would lower the general sensitiveness; but, as, when a yellow screen is used, the exposure has to be prolonged, the necessary increase of exposure with the stained plate would not be a disadvantage.

DEVELOPING FORMULÆ.

Amongst the very numerous suggestions that have reached us in connexion with our article on this subject some weeks ago are several which aim more or less directly at the establishment of a universal or standard developing formula that shall be applicable, with slight modifications, to all brands of plates and to the different conditions of exposure, and the so-called "standard" formula of the Society of Amateur Photographers of New York is indicated as an example of what is required.

With regard to the feasibility of such a universal developer, we can only say, at the very outset, that that formula, or, indeed, any other, good or bad, will answer equally well for the purpose of a "standard" to be used under all or any conditions; in fact, to put the matter in the form of a *reductio ad absurdum*, the formula itself is not of the slightest importance, its practical value lying in the modifications made to meet the varying conditions under which it is used. if we may put it in that way. In other words, it may be said at once plainly to those who are in pursuit of the *ignis fatuus*, a "standard developing formula," that such a thing is impossible, unless we take plain water as the standard, to be varied by the addition of other substances as necessity may require.

Even in the days of wet collodion, when the sensitive films prepared by different operators, in spite of the differences in the collodion used and the strength and condition of the bath, possessed probably a far closer resemblance to one another than do the gelatine films prepared by different makers at the present day, there was no such thing thought of as a standard developer. It is true that the general strength of the developer in its normal condition for studio use was fifteen grains of ferrous sulphate to the ounce of water acidified with fifteen minims of acetic acid; but these proportions were by no means adhered to by different operators, even under similar conditions while the same operator would scarcely have employed the same solution out of doors that he used in the studio.

Considering, then, the wide difference that exists between the characteristics of different makes of gelatine plates, what probability can there be of the respective manufacturers combining to establish a universal formula; looking at the fact, too, of the widely different requirements that exist in the development respectively of a portrait in the studio and in an ordinary room, of a well-lit landscape and a dark interior, or, indeed, between any two subjects it is possible to select, how is it possible for any one maker to establish anything more than approximately resembling a standard developer, even for the plates of his own make and under ordinary and normal conditions? The published formulæ are those which the respective plate-manufacturers find to be the most suitable for their particular films under certain conditions—generally for portraits in the studio, and a comparison of the different formulæ given in our Almanac will sufficiently show how varied are the requirements of different plates, and how unlikely it is that any combination of makers will ever arrive at uniformity in this respect.

We are quite willing to agree with some of our correspondents in the belief that there is an unnecessary amount of divergence between many of the formulæ published, but then it must be borne in mind that different opinions may exist, and that, with one and the same plate, different operators may hold as many different views as to which is the best method of development. One may prefer pyro ammonia, another pyro soda, while others prefer hydroquinone, metol, or ferrous oxalate, and, to a large extent, this is but a matter of individual taste. It seems to be universally agreed by the most experienced workers that pyro ammonia still remains the most elastic—the best all-round developer, though pyro soda, in point of convenience, is, perhaps, the more general favourite. Perhaps the very best average of results, in competent hands, will accrue from the use of the first-named, but it is beyond doubt that, even at the present day, there are some plates on the market that require the most careful treatment when that form of development is used, whereas, with pyro soda, they will bear a considerable amount of rough handling, although that developer does not offer the same power and latitude.

But, taking any one particular form of developer, it is quite impossible to establish a standard that shall be capable of use with different kinds of plates, even under normal conditions. The combination of pyro, ammonia, and bromide, for instance, that would be a quick developer for one kind of plate, might possibly be an extremely slow one for another make, for it is well known that some films absolutely require a much larger proportion of bromide than others, while twice the quantity of pyro that would give a dense image on one plate would be insufficient with another. The same may be said with equal truth of other developing agents. With one kind of plates, for instance, metol may be used without bromide, and will give dense, vigorous images, while, under the same conditions, with another plate, a thin, grey, ghostly picture is all that results.

Until photographers give more attention to the study of development, and less to the search for an automatic method, there will be no possibility of arriving at anything like a standard, and, when any such is arrived at, it is perfectly clear that it cannot possibly be either a single solution or even a two-solution developer. For any given make of plate the necessity must always exist for more or less varying the proportion of alkali and reducing agent, according to the conditions of subject and exposure; consequently a single solution, or a mixture of two solutions in definite proportions, is only possible under one set of conditions; and, if the bromide be combined with either one or the other of the two solutions, circumstances may arise, even with the plate for which the mixture is specially intended, under which the relative proportions of the three ingredients get "out of gear." But, if the same solutions are to be used for plates of widely different character so far as the quantity of bromide they require is concerned, it will be quite impossible to preserve the correct proportion of the different ingredients without having three separate solutions.

This, in fact, brings us back to the old method, introduced in these columns a dozen or more years ago, under the name of "rational development," in which three solutions of definite strength are kept—ten per cent. solutions are convenient—and mixed *pro re natâ*. This we believe to be the nearest approach possible to a "standard" developer, but it, of course, necessitates at least some little trouble in calculation, if it does not lay any very great strain upon the mental faculties; but we fear that it is this necessity for thought and calculation that is at the bottom of the whole matter, and that gives rise to the cry for standard, or automatic, development.

It is probably the extreme convenience of pyro and ammonia in this style of development that gives that combination the first place in the estimation of the more careful workers. The ready solubility of pyro, and high developing value of concentrated ammonia render them extremely easy of use in strong stock solutions; while the lower degree of solubility of hydroquinone, metol, and similar substances, as well as of the carbonates, make ten per cent., or even less concentrated solutions, an impossibility. Still the same principle can be followed, and, if the makers of plates would, one and all, in addition to giving a definite formula for stock developing solutions, state, as some, at least, do, the quantities per ounce of developer of the different materials best suited to the plates under "nominal" conditions, then photographers would be within measurable distance of being able to deal with any kind of plate whatever with the minimum of trouble.

Eclipse Expeditions.—Sir George Baden-Powell's yacht *Ontario*, with a portion of the British Government Eclipse Expedition, sailed, last Friday, from Vardo for Mellor Bay, Nova Zembla. In view of the different expeditions now on the way, one is very much inclined to question if "old Sol," with all his previous eclipses, has ever been flattered by the attendance of so many English scientists, dilettanti scientists, and excursionists, as he is in the present one. It is to be hoped that these expeditions *de luxe* will end in a great acquisition to our present knowledge, and not make good an old adage, that "too many cooks," &c.

Kew Bridge.—This familiar object, so well known to Metropolitan artists, and some photographers (as adjacent to Strand-on-the-Green), is to be pulled down, and replaced by a new one. This would have been done long ago but that the Middlesex and Surrey County Councils could not be brought into agreement in the matter. That safety required a new bridge long ago, there is no question. While the new bridge is being erected, the old one will be replaced by a temporary one. As the commencement of operations will not be long delayed, those who wish to obtain pictures including the bridge should lose no time in taking them. Strand-on-the-Green does not seem to be so well known amongst photographers as it deserves to be, and we question if there is to be found within half a dozen miles of Hyde Park Corner so much real picturesque river scenery, and food for the camera, in so small a space, as there is at Strand-on-the-Green. It is easily come-atable by road, train, or boat.

The Spy Scare Still On.—According to a Dalziel telegram from Metz one day last week, two French tourists, father and son, who live in the suburbs of Paris, were arrested for taking photographs with a hand camera in the vicinity of the Fort Zastrow. The telegram concludes: "They were detained in custody pending the development of the negatives." We merely allude to the telegram for the purpose of once more impressing upon English photographic tourists who may just now be about spending their holidays abroad, particularly on the Franco-German frontier, which abounds in food for the camera, the inconvenience they may unconsciously incur. In the neighbourhood of every fort in this district there are always patrols, or sentinels, anxious for their services to be recognised at headquarters, and, if they happen to see any one with a camera, he is at once treated as a suspect. If he happens to take a view, even if the fort is not in sight, he is forthwith arrested, and has to submit to inconveniences, not to say, in some instances, indignities, and necessarily delay. These may sometimes form an amusing anecdote when relate at home, but they are best avoided when on pleasure bent.

The British Medical Association *versus* the Pharmaceutical Association.—Conventions and congresses are now apparently in full season—last week especially. Then, amongst others, two what may be termed, in a sense, trades union congresses were held, namely, that of the British Medical Association, and that of the Pharmaceutical Association. The former, however, scarcely comes under the title of "trades union," because it seldom exercises its privileges as such, though the latter, under the auspices of the Pharmaceutical Society, undoubtedly does to the fullest extent. It might be supposed that both these bodies would row in unison; but, from what took place at the congresses, it is clear they do not. The pharmaceutists complain that the "medicos" do not make the same use of drugs as they used to do, and at the same time insinuate that they know, from their training, very little about the chemistry of what they prescribe. The medicos, on the other hand, complain of chemists counter-prescribing, and condemn the practice of medicine by chemists and druggists, and suggest prosecutions against them under the Apothecaries Act.

THERE is no question that, if the medical societies were to put their powers in force against the pharmaceutical chemists in the same way that the latter do against those who infringe their trade rights, it would fare badly with them, one and all. Chemists and druggists supply medicines for all and every ailment when applied to for them, though they are not qualified to do so; but, if any of the informers, or spies, of their trades union can find, or induce, say, a photographic dealer to supply a small quantity of anything included in the schedule, such as bichloride of mercury or cyanide of potassium, he is forthwith sued, or threatened to be sued, unless he at once remits the five pounds' penalty and lawyer's fees. This many do to save further expense. Not long ago a firm of oilmen were mulct in a penalty of five pounds and costs for selling a well-known brand of "fly papers." This proves that only pharmaceutical chemists are qualified to sell fly papers. How long, if the matter were vigorously taken in hand by those concerned, would this trades-union monopoly exist?

DIGRESSIONS.

VIII.—Some of the Harvest.

Leaving out of consideration professional portraiture, the bulk of the annual crop of negatives will have been gathered in by the end of the month, and the Exhibition season, entering on its wild career, with those critics who want to hunt with the hounds and run with the hare still not able to answer the question, "Under which king, Bezonian?" The harvest it is, of course, not possible to estimate with anything approaching correctness, but some idea of the luxuriant crop may be guessed by a glance at one small field. It is estimated that over 5000 exposures were made during five days of the Convention week. The quantity, however, great as it is, will leave a considerable aftermath of exposed plates to be brought home from the autumn holidays.

The quantity of the produce we can approximately estimate by the output of material, and know it to be increasing and enormous, beaten indeed only by the marvellous run on cycles, and I would suggest that the manufacturers should take into consideration some liberal scheme of almshouses for those who spend their all in the pursuit of the art which is more profitable to them than to anybody else. Its quality, however, is to a great extent a matter of speculation or individual taste and judgment. Let us look over, or rather speculate over, the outcome of the year's work as far as the not very easy circumstances of the case will allow.

In professional photography, except in the hands of a few, I fear, something very like stagnation exists, but those few are moving. It seems to me that the usual photographer never does anything towards increasing his business, except in the usual objectionable way. He will tout, cut prices, "do 'em 'arf price during Whitsuntide," or for nothing every Monday, or if they will only come a thousand at a time, and advertise that his "goods" are the best in the market. It is only fair to say that these are lower down than the class I have in my mind at present. But I am afraid it is the middle class that is the stagnant class, the only effort at improvement they attempt being to imitate the works of others when they hear they are "paying;" there is never any attempt to break out in a fresh place, or improve the art for the art's sake; no accident ever happens to the middle-class photographer, and moments of inspiration are unknown. There are men who cannot make a bad picture, neither can they do a good one, and are fully content if they can do as good as their neighbours, and look in his window for a *lead*. Mediocrity is the saddest fate that could happen, if, indeed, it is not surpassed by the dreary sameness in the work of the photographer whose work is all alike at the highest level of mechanical perfection. Perfection easily becomes a calamity, especially when it is produced in quantity. It becomes a machine-made article, wanting in inspiration. I once heard a photographer exclaim, "Thank goodness, I can still make a thoroughly bad picture; it is not a lost art with me," and felt the lesson if I did not quite understand it at the time. I am not sure that the beauty of a good deal of the work of Rejlander and Mrs. Cameron was not so much in spite of, as because of, their faults. Absolute perfection does not match creation; it is unnatural; there is no blind spot in its eye. [This is not written for the youngest amateur, I don't want to demoralise him, and I hope he will skip it. He may trust himself not to be too perfect for some years.]

To resume. I don't believe that among the bulk of professional photographers there has been the least decrease in retouching of the worst kind, although its practice is falling off considerably among the better class, which I am afraid I am obliged to estimate at about a score; this is not encouraging. But there is an upper middle-class business about which I am beginning to hope, the class that I am afraid has been having the worst of it for years. The members of this class are certainly doing better, and more of them are showing at exhibitions. They are showing better work: they are using plainer backgrounds; the palm-tree is abolished; a full-length figure can walk about without kicking the crockery over. (I have seen a full-length figure which must have been built into its place with flower-pots to be photographed.) They show an appreciation of breadth of effect and simplicity. They acknowledge that they now see the necessity of reading works *on* art, as well as looking at works *of* art; they cannot suppress retouching all at once, it would be business suicide with an ignorant public, but they are personally disgusted with it as at present practised.

Of the residuum, the immense residuum, the makers of photograms, who set up their tents on the sands, I have seen nothing this year, but I hear they are as flourishing as ever. Neither can I say anything of process work, or radiography, two results of science which seem beyond the boundaries of our art.

It is the amateur who is the backbone of true photography, after all, but it requires some courage to say so, and it is pleasant to notice that the hand camera is gradually being raised from the position of a frivolous, or mischievous, or scientific, toy into the dignity of a serious tool for the production of pictorial photographs. This I notice all round. Among others there is a certain club whose excursions have lasted without default for between thirty and forty years, some members of which are conservative in the dimensions of their apparatus; but I have noticed during the last three or four years that the size of their cameras has been dwindling. The usual size used to be 10×8; when the wet process went out and gelatine came in, the weight was reduced to about 28 lbs.; now the $8\frac{1}{2} \times 6\frac{1}{2}$ has taken its place, and a hand camera often accompanies the older instrument, to take the chief place after a decent interval.

It is most gratifying to find that the art of the members increases as the weight of their tools decreases. There are only two now who talk apparatus where there once was a score, and even that is only about the internal machinery of hand cameras. But I must say that, when a camera "jams," the interest is intense, and all the coats in the company are instantly thrown on the ground to make a tent for half the unfortunate owner's body, so that he may rectify the machinery, which, like the assistant secretary I intended to have mentioned above, but will try not to forget again, would go wrong at a trying time. If anybody doubts this setting up of a dark room of garments, I can confute him, for I have all the incidents of such a chain of events duly set down in the art that cannot lie—although I am always trying to prove that the latter statement is a libel.

Thousands of half-plate negatives and snap-shots are, of course, still taken annually of many of our popular castles, abbeys, churches, ruins, and other objects which go under the heading of places of interest. But a change is coming over our amateurs. I visited, with a party of photographers, in early summer, one of our most picturesque mediæval towns, with church, castle, river, all complete. I noticed that the chief attraction was the river. I don't think a single plate was exposed in the church, one of the finest in England, and very few in the castle, although it was full of "objects." One member of the party found the top of the keep a capital place for getting clouds, and expended his plates in this way, although there was nothing very attractive in the sky at the time, rather than on Norman arches and mediæval architecture. The fact is, the advanced amateur has at last discovered that it is no longer interesting or profitable to take photographs of places of which he requires only a single copy, when he can get them beautifully executed for a single sixpence each, or, if he would be economical as well as encourage the foreigner, in "German" for the sum of one penny. He has at last learnt that more pictorial, if not such easy, subjects are better worthy of his camera; and he takes more interest in looking up little riverside bits, with cattle, sheep, or rustic figures, and gets his local views from the professional.

I said just now "beautifully executed" local views could be obtained. That, however, depends upon whether there is a local photographer in the town who takes, perhaps, more than a business interest in his work. The work done by travelling photographers for large firms is often very poor. Printed from reproduced negatives made thin for the purpose of quick printing, without regard to quality, they are black and without atmosphere, and not worth even the small sum for which they are nearly given away.

The societies are getting along at the usual jog-trot pace, reiterating the usual topics. In a method, in the scientific part of which there is so little to teach, this is the most useful thing they can do. But some, and perhaps most, of the suppliers of papers, rather than not keep on supplying papers, write on subjects

that are only very remotely connected with our art, or, worse still, that they know nothing about. Can it be that such delightful subjects as developers, emulsion-making, ceramic enamels, and isochromatics are played out, and process work only left, that a representative man of the chemical-mixing persuasion must write a paper on art for the purpose of saying (*not*, he is careful to say, on behalf of the Society of which he is Assistant Secretary, though it had much that appearance) to art, "You're another, and ought never to have been written about at all?" Now, the art side has no jealousy of this sort of the scientific side, and rejoices to see the severely scientific nature of the papers now being read at the Royal. How Mr. Child Bayley could have deserted the delights of emulsion-making, for which he is admirably fitted, if a little late, for the thorny paths of art, a subject in which he has shown himself inexperienced, surprises me. It is as if I, the most unmathematical person in the world, insisted on reading a paper on "fluxions," and demanding its publication in the *Philosophical Transactions*. Not that I think emulsion-making wanted reiterating, for it is better done for us by the manufacturers than Mr. Child Bayley can tell us how to do it. But *we*—the art side—never object to his writing about it as often as he likes. I must say this, any how, even if the sky falls, that the Council of the Royal could not have spent the money of the Society half so well as in sending its Assistant Secretary to the late Convention to learn a little art before he took to writing on the subject. But the Royal always misses its opportunities. He would have seen a little exhibition there consisting entirely of pictorial photographs, from which he would have learnt what such photographs should be, and —what would have been of, perhaps, more use to him—how to hang them. This he would have learnt from a local society too, for the Leeds Committee were entirely responsible for the splendid hanging. By application to the Committee, he might also have secured police protection to prevent any one teaching him anything. He might have learned from the pictures alone, for he is of the second-hand opinion that art cannot be taught; that all art can be better learned by merely looking at good photographs—how does he know when he comes to a good one?—than by reading about art. I am only an artist, but I cannot see how anything can be learned by merely looking at good pictures without the aid of some written or spoken description of *why* they are good, or some preliminary knowledge of the same kind got from talk or books. This kind of tasting only tickles the palate, it doesn't feed. I should as soon expect a scientific tyro to give me a quantitive and qualitative analysis of a bottle of physic by simply holding it up to the light. H. P. Robinson.

COLLODIO-BROMIDE AND TRANSPARENCIES FOR PHOTOGRAVURE.

[Royal Photographic Society.]

In order to produce a photogravure plate it is first of all necessary to have a transparency made from your negative, and it is only by taking the greatest care that this shall be perfect for its purpose that a perfect plate can be secured.

It is necessary that this transparency should have every tone of the subject clearly defined, and with as wide a range of gradation as possible. It must start in the highest lights, with all but bare glass in every case, but the density of the deepest shadows must be in accordance, not so much with the subject as the nature of the grain to be used on the copper plate.

Roughly you may put it in this way:—

1. Very delicate subjects with fine detail require a very fine even dust grain on the copper plate, and a very delicate transparency; all the detail must be there, but the deepest shadows must be decidedly thin.

2. All ordinary subjects, including negatives from nature, such as would print well on silver paper.

3. Reproductions of paintings with heavy masses of shadow, and very large plates, such as require a coarse grain in order to avoid muddiness.

For large masses of shadow and heavy subjects, it is necessary to get very much wider range of tone in the transparency, because one must use a larger dust grain on the plate, and, in order to get the requisite black, the etching solutions must act longer on each tone, *i.e.*, the total time of etching must be very much longer. Instead of an even-sized grain for such subjects, I prefer to use a mixed bitumen and resin grain. First lay a coarse bitumen grain, rather wide apart on the plate, and affix by heat in the usual way, then lay a copious very fine resin grain over the bitumen, and heat only sufficient to firmly affix it to the plate. With such a grain the fine particles of resin will soon be undercut in the deepest shadows by the etching solution, leaving the bitumen to form the ink-holding capacity of the plate, but the resin will secure delicate half-tones in the lighter parts of the picture, and the few dots of white in between caused by the bitumen will add to their brilliancy.

I have here, and will pass round, two transparencies. One is a carbon print, such as would yield a good photogravure; it is from a negative from nature, that negative being of such density that it will give all the gradations and density required, by simply printing in autotype tissue. Where your negative is of this type and the required size, I think this process may always be relied upon to secure the finest results.

The second is a much more delicate subject, being a reproduction of a silver point drawing. Such a subject requires a very fine grain, preferably white resin, and, as that grain is very easily undercut by the etching solutions, it is necessary to get all the gradation in a very much closer scale.

Perhaps the easiest method of securing a transparency of any desired kind is to use collodion emulsion. Gelatine dry plates I know will do very well for many subjects, but I have always found collodion more certain and less difficult.

For the emulsion I prefer as simple a formula as possible, and, after experimenting with many, I settled on an unwashed bromide emulsion as the most suitable. The emulsion is made in bulk, using an excess of bromide, so that in the unwashed state it is very insensitive; by using it in this form, and afterwards washing out the excess of bromide, you may coat the plate in a good light, when all defects may be at once noted, dust, specks, &c., and then take the plate into a safer light, whilst washing out the excess of bromide.

With such a plate any class of transparency required may be obtained with ease, by varying the exposure and length of development, a strong, plucky picture from a very thin negative, or *vice versâ*. I find it best with line subjects to get only a very faint image with the development and secure the requisite density by after-intensification.

To prepare 10 ozs. of the emulsion, dissolve 250 grains of silver nitrate in a test tube, with 2½ drachms of water, and add 2½ ozs. of warm alcohol (·805), weigh out 50 grains of pyroxyline, and place in a 12 oz. amber glass bottle, add the silver solution and 5 ozs. of ether (·725) to dissolve the cotton.

In 2½ ozs. of alcohol dissolve 200 grains of zinc bromide, take the solutions into the dark room, and gradually add the bromide to the collodion, shaking well between each addition.

For development I have always used the formula for pyro and ammonia given by Mr. Brooks:—

No. 1.

Saturated solution of carbonate ammonia ..	4 ozs.
Potassium bromide	4 drachms.
Water to	20 ozs.

No. 2.

Pyrogallic acid	6 drachms.
Alcohol	4 ozs.

For a half-plate take ½ oz of No. 1 and 6 to 12 minims of No. 2, according to the class of transparency required.

Either hypo or cyanide may be used for fixing, but, if the negative is to be intensified, I prefer cyanide, as the film can be washed in a shorter time; I never use a substratum, but only an edging of rubber solution; dishes are not necessary, and any size plate may be coated with ease without the uncertainty of using a different batch of emulsion, as you would probably have to do with gelatine plates. A heavily weighted stone jar, with a pad fixed in the mouth, should stand in the sink to support the plate during development, &c.

It is always advisable to secure the necessary density of half-tone subjects by development or acid pyro intensification, but for line work I prefer to get a very faint, clear image with the developer, and intensify with lead; after fixing, wash well, and flow over with

Nitrate of lead	2 ozs.
Red prussiate potash	2 „
Water to	20 „

Wash well under the tap, and flow over with water 10 ozs., nitric acid ½ drachm, wash, and flow with sulphide of ammonium, wash, and again apply the acid. The very finest line work may be copied in this manner without fear of the lines filling.

For keeping the emulsion, I use a 10 oz. ordinary wet-collodion pourer with cap, kept in a tin with loose-fitting cover, so that it may be easily taken off with one hand in the dark room. For copying from line subjects on yellow or toned papers, add a few drops of an alcoholic solution of erythrosine to the collodion, and use a faint yellow screen.

Extreme contrast, such as required for line work, can be much more easily obtained with an unwashed than with a washed emulsion.

For line work in photogravure I prefer to have a very small amount of dust grain on the plate, and, if the drawing contains brush work or large black patches, to let these go in the etching, and recover their values afterwards by re-etching. If you attempt to use a sufficiently large dust grain to give brilliant deep blacks, the fineat lines would etch broken or rotten.

I will pass round an example. There are in this drawing a great number of very fine lines, together with solid patches of black; these fine lines, if etched over a coarse enough grain to suit the black patches, would have been broken up into dots, but, by keeping the grain fine, the fine lines are all sweet and clean, and the solid blacks, which were undercut in the etching, have been recovered by after-biting.

I would like to mention a wrinkle in connexion with line negatives. One sometimes wishes to copy a print on coloured paper, and I have found it more easy to bleach out the colour than to attempt to make a good line negative by the use of orthochromatic plates and a yellow screen.

I may say, the only difficulty likely to be met with in making the collodion emulsion is with the pyroxyline; this should dissolve without leaving any glutinous particles. The best way is to try several brands, and, when you get a suitable one, buy a quantity, a little sand of insoluble matter in the emulsion will not matter, but always shun a cotton which gives a flossy collodion.

E. Sanger Shepherd.

CELLULOSE AND ITS DERIVATIVES.*

We do not propose on this occasion to do more than demonstrate the main properties of the solution, and of the new forms of structureless cellulose to which it gives rise.

We pass on to the third group of soluble and plastic compounds of cellulose, those formed by the reaction of the OH groups of cellulose with negative or acid and radicals; these are the acid ethers or esters.

Of the possible esters of cellulose, the following have been investigated: the nitrates, acetates, benzoates, and sulphates.

Whereas, however, the first-named take a prominent place in the industrial world, the three latter are known only to specialists. We need only briefly remind our audience of the chief uses of the nitrates of cellulose. They are two, and in strong contrast to one another. The higher nitrates of cellulose are the basis of the modern high explosives, the so-called smokeless powders and the like; the lower are employed as the basis of the many forms of transparent and opaque films employed in photography, of celluloid, xylonite, and other plastic materials of this group, also of the well-known collodion which played so important a part in the early days of photography, and still more recently as the basis of the new "artificial silk" industry. Avoiding the details of their applications, we may say a few words on the more important chemical feature of these products.

Cellulose combines with nitric acid in several proportions. Writing the compound as $C_6H_7O_2 \cdot (OH)_3$, each of the OH groups may be made to react with HNO_3 or nitric acid, each OH becoming in succession O . NO_2, with a corresponding increase of weight of the resulting nitrate. What we wish to point out is, that with the entrance of these highly negative or acid groups the physical properties of the parent molecule are not profoundly modified. The products are soluble in various liquids, *e.g.*, ether-alcohol, nitro-benzine, nitro-glycerine, which are without action on cellulose, but the properties of the compounds in solution are very much those of cellulose itself as seen in the solutions previously described. This could not be better illustrated than in the processes of spinning and preparing the "artificial silk." What is actually spun or drawn is a viscous collodion, the ether-alcohol solution of the intermediate nitrate. The resulting thread after elimination of the solvent is therefore the explosive compound or nitrate. But the nitric groups are easily removed by a chemical treatment. The yarn is treated with ammonium sulphide for this purpose, and there finally results a thread of pure cellulose, with very slight attendant change of physical properties. (See *J. Soc. Chem. Ind.*, June, 1896.) The cellulose is therefore taken through a cycle of chemical treatments without sensible change in properties, in order to take advantage (while in the intermediate stage of nitrate and in this form soluble in suitable solvents) of the plastic and structural properties which are evidently those of the parent molecule.

The acetates stand next to the nitrates in order of technical interest. They are not easily prepared from the fibrous celluloses, but are obtained by simple reactions from the cellulose regenerated from solutions as sulpho-carbonates. These reactions are described in a paper which we communicated to the Chemical Society in 1895. (See *Journal*, p. 433.) The acetates are in physical properties similar to the nitrates. They are, however, non-explosive and withstand high temperatures, melting above 200° C. to a clear liquid. They are in fact, as might be expected, extremely stable compounds, and in many respects, therefore, they are superior to the nitrates for industrial uses. We are taking steps to have them manufactured on the industrial scale, and hope very soon to be able to offer them to photographers.

It would be interesting, if only on theoretical grounds, to make comparative trials of the well-known, but now relatively obsolete, collodion processes, with the acetates used in place of the nitrates. If any expert minded to undertake such investigations will communicate with us, we shall be able to put him in the way of obtaining supplies of the material. We shall not discuss the probable uses of these new products in detail, but content ourselves with a demonstration of their properties, and leave the matter in the hands of the specialists.

The benzoates again are compounds easily prepared from the more reactive celluloses obtained from the sulpho-carbonate solutions. They have been even less investigated than the acetates. They have the same general properties, and will, no doubt, in due course find their application.

These compounds will be found more fully described in our book on *Cellulose* (Longmans, 1895). On this occasion we have merely to bring them together in a certain connexion, *i.e.*, with the view of making photographers acquainted with the possibly useful forms of cellulose and its compounds. The annexed table sums up the results of this discussion, and gives a bird's-eye view of these various products regarded, from the present practical point of view, as methods of bringing cellulose into solution.

Soluble Compounds of Cellulose.

A. By direct treatment with solvents: the cellulose in solution as a species of double salt: the solutions are aqueous.

1. Neutral. Zinc chloride.
2. Acid. Zinc chloride in hydrochloric acid.
3. Basic. Cuprammonium compounds.

B. Compounds previously prepared by synthetical reactions with alcoholic OH groups.

1. Sodium hydrate and carbon bisulphide. Synthesis of sulpho-carbonate in two stages. Solutions aqueous, and of course alkaline.
2. Acid esters of cellulose: compounds of "neutral" properties.

Nitrates. Acetates. Benzoates.

Soluble in: ether, alcohol, acetone, chloroform, glacial acetic acid, &c.

We now return for a few moments, in conclusion, to general considerations.

Cellulose, as the colloid medium for the photo-sensitive substance, has of late years given place largely to its rival gelatine. Gelatine is a substance differing radically in composition and constitution from cellulose, having, however, a fairly close resemblance to cellulose in physical properties, more especially in aqueous solution.

If we are to have positive knowledge of the actual function of the "medium" in the photographic system, it must be made the subject of definite scientific investigation. An important aid to investigation is the power to vary at will the several factors of a result. In cellulose, which includes, we may say, a number of natural products of different constitution, and in the groups of derivatives which may be formed from it, we have a substance which may be studied under a range of suitable variations. The purpose of this demonstration has been to suggest methods of manipulating various forms of the substance, the details of which will readily occur to those familiar with the technicalities of the art. Those who have not followed us from this point of view will, we hope, at least have got some fresh insight into a very attractive province of the chemistry of nature's raw materials.

Cross, Bevan and Beadle.

* Concluded from page 488.

PHOTOGRAPHIC WORKERS AT WORK.

X.—The Autotype Company at Ealing Dean.

The Autotype Company, whose reproductions of the works, both of old masters and of modern artists, are to be met with far and wide, is one of the few photographic firms which enjoy a reputation both inside and without photographic circles. To the outsider they appeal by the reproductions just referred to, by the illustrations of coins, medals, &c., in the British and other museums, and as proprietors of handsome showrooms in New Oxford-street. To the photographer, on the other hand, they are known as manufacturers of carbon tissue and implements for carbon printing, as enlargers and printers by that process, and, more recently, as makers of platinum paper.

The history of the firm, whose prosperity seems now assured, has been a chequered one, and it is not the least curious circumstance in connexion with its career that, while formed originally to work the Swan patent for pigment printing, its business in this respect has enormously increased, even since the expiration of the main patent. The works were started in 1868, at Willesden, in premises adjoining the house of Mr. Ernest Edwards, who was interested in the Company at that time; three months later they were shifted to Brixton, and, after fifteen months there, a remove was made to the present site at Ealing Dean, where they have grown steadily and continuously to their present size. We might mention here that we had the pleasure of Mr. H. J. Burton's guidance, a gentleman who has been with the firm since its commencement, and who is now works technical manager. The Gallery, where the productions of the Company are on sale, in like manner started at No. 5, Haymarket. Messrs. Tooth's; removed thence to Rathbone-place, where a disastrous fire occurred; and was transferred finally to the present site, at No. 74, New Oxford-street.

At a little distance from Castle Hill Station, on the Great Western Railway, the Works of the Company are to be found, and entering them, we are first conducted to see the manufacture of carbon tissue and of transfer paper. The gelatine, which enters the works in the form of thin sheets, is first soaked in water and melted up, and is then transferred to metal churns in which it is kept in continual agitation for some hours—a process designed to get rid of a certain lumpiness which it otherwise would possess—after which churning it is run out and allowed to solidify in large masses of jelly.

In the mean while the pigment, which is received from its manufacturers ground to a very fine state of subdivision, is being once more ground up in a paint mill with a small portion of the gelatine, the bulk of the latter only being added when these have been thoroughly incorporated. The jellies so made are mixed in the necessary proportions to secure the result aimed at, and after the colour has been finally tested on slips of opal glass, a pile of which were to be seen here, it is transferred to the coating rooms. Of these rooms there are two, and a description of one of them must serve for both, since they are very much alike, the chief difference being that sensitive tissues, *i.e.* those containing the bichromate, are made in one of the rooms only, and not in either indiscriminately, although both are fitted for their production, if necessary.

The coating machine is a gallows-like erection, carrying a roller at its upper extremity. The paper in large rolls is fitted in a frame, which carries four rolls, and the end of the first length is led round rollers till it passes round under one at about three feet from the floor. This roller runs in a trough of pigmented or plain gelatine (pigmented for the tissue, plain for transfer papers), which is fed upwards by a form of cam known as a snail, so that at the lowest part of its course the paper is just below the surface of the liquid gelatine. It picks up a coating of this as it travels on, and is led straight up, over the roller at the top of the machine and down an inclined plane on the other side on to a long table. This table carries a broad web of canvas down its entire length, on the endless-belt principle although the web itself is not strictly speaking endless, and the web, always travelling on away from the coating machine, carries on its surface the coated paper. As soon as the paper reaches this table it is taken in hand by a girl, who slips a bar of wood underneath the band and cuts off a length of about twelve feet six inches, and attaches to the two ends of this length strips of wood by means of clips. When this paper has travelled down the table, the two ends of the bar engage in a carrier, and another girl, pulling a cord, raises the band in the form of a loop hanging over it to the top of a scaffold, from whence a third girl, with a long carrier, like a magnified broom, picks off the bar by its two ends and conveys it and the band of tissue hanging over it to wooden pegs on which it is hung to dry. This takes place by the next day, sometimes sooner, since each room is heated by steam pipes and is provided with a fan for ventilating purposes. The motive power for one of the coating rooms is in the form of a two-and-a-half horse Gardner gas engine, which does its work quietly and effectively. The rest of the power required throughout the works is furnished by a pair of steam engines, the boilers for which also supply hot water for printing purposes and the steam for heating, the condensed steam providing a constant and ample allowance of distilled water.

The length of time taken by the tissue and transfer papers in drying matters little within reasonable limits, except in the case of the sensitive tissue. Then, on the other hand, it becomes very important, and has to be dried within a certain time to be satisfactory. Sensitive tissues are coated on Monday and Thursday, so that orders received on Tuesdays and Fridays for this product are filled by that made the day before. The coating rooms are each capable of containing and drying upwards of a hundred lengths of tissue. The water supply is situated in a tower attached to the tissue-making department, and is contained in four large tanks for the regular supply of cold water, one still bigger as a reserve, and one containing hot water.

The next department to be visited by us was that in which negative-making was being carried on, here pictures are copied and enlarged negatives made for the subsequent operations of carbon printing, photogravure, collotype, &c. Outside the studio where much of this work is done, stands a colossal easel, for carrying very large pictures for copying purposes. This Goliath is over ten feet high and travels along two G.W.R. rails firmly bedded in concrete. To secure rigidity, the whole structure is of the most substantial nature. Cameras, in the ordinary sense of the word, are not usually employed, the room in which the operator works acting as the camera, and it is rarely the case that a negative is made direct, a reversing mirror being used with the camera at right angles to the picture; the smaller negatives made in the studio are made, however, in a camera.

The wet-collodion process is extensively employed for enlarging and copying, orthochromatic dry plates being used when rendered necessary by the subject being in colours. The collodion used is made by the Company with pyroxyline, which is also of their manufacture, and many of the dry plates employed are of their make also. A dark room for coating wet plates contains nothing very novel as a rule, but the Autotype Company's was rendered interesting by the fact that they frequently deal with wet plates sixty-five inches in length by thirty-six in breadth! To manipulate these huge plates, a frame is used having a handle at one corner and supported in its centre by a universal joint. Three operators are required; one pours the collodion on the plate; another, holding the frame by the handle, inclines the plate until it is covered, and then pours it off into a funnel held by the third. The plate is next transferred to a bath of correspondingly large proportions swinging on pivots. This bath is of the well pattern, and, being fixed vertically, receives twelve gallons of silver solution into its well, after which the plate is placed in it erect, supported just above the well on ebonite pegs, and a lid encloses plate and solution in a light-tight and dust-tight box. The bath is then swung down into a horizontal position, when the liquid flows over the plate, and in this position it is allowed to remain for about a quarter of an hour, when it is once more brought to the vertical again, and left in the bath for some time to drain. Exposure is made in one of the rooms devoted to the operation, development being carried on in a special dark room, and intensification in another. A quart of developer is found to be sufficient if properly applied, and the very large plates are fixed and washed in the sink in which they were developed, the washing being carried out by a rose and length of rubber tubing. "As we can't take the plate to the water," says Mr. Burton, "we bring the water to the plate." A large dipping bath is used for fixing smaller plates in, "smaller plates" at Ealing referring to such sizes as 36×28 and under.

The silver baths, where so much wet-plate work is carried on, need particular attention, and we found them occupying several carboys. Cotton-wool, rinsed first with alcohol, then with tap water, and finally with distilled water, is employed for filtering, and some idea of the amount of wet-plate work done can be got from the fact that, as we were informed, no less than a hundred ounces of nitrate are used per month in this one department. The negatives are varnished in a room devoted to the purpose, being heated in gas-heated ovens for the purpose. In the varnishing room too we found a large gas-holder containing oxygen for the limelight. Daylight is much preferred at Ealing for enlarging purposes, but occasionally in winter time it cannot be got, and recourse is had to the limelight. For this purpose we were shown a twenty-two inch condenser, each lens of which weighs three quarters of a hundredweight, an instrument capable of lighting a 12×10 plate easily. Triplets, Grubbs, and Darlots are the lenses employed for enlarging and copying, of which the triplets seem to be the favourites; and numerous lenses are in constant use, as well as many mirrors.

Carbon printing was the department to which we next turned our attention. This is carried on in a large building divided into four or five rooms, each of which resembles the rest. Each room contains three or four large tables travelling on rails by means of flanged wheels. When these tables are drawn right into the room, they are in a subdued light, which is kept by means of yellow fabric of a safe character for filling and emptying the frames. The tables, when loaded with frames, are pushed along the rails until they are just outside the rooms, they are then under glass for printing in rainy weather. In fine weather they can be pushed still further out until right out of doors. Johnson's and Burton's actinometers are those most frequently employed, the printing frames having plate-glass fronts and, being employed for carbon work only, backs which are not hinged. The large negatives already referred to are printed in a frame capable of carrying a negative 68 × 43 inches, faced up with plate glass half an inch thick. This frame is mounted on a truck of its own, and swings on pivots for convenience in getting to its back. The tissue in actual use in the printing rooms is kept in a series of bins, and is cut up by means of a very blunt knife on a sheet of thick zinc.

When printed, the tissue is taken to the developing room, which is one of the largest in the works. Along the sides and ends of this room are large sinks, eighteen in number, some of which are over six feet long by three or four wide. Here the prints are mounted, developed, alumed, washed, and dried in a manner familiar to most of our readers. For convenience in developing the prints in the large sinks boards are sometimes used, which float on the surface of the water and carry the print, the water is then taken up in a sponge and squeezed over the print to develop it. For double transfer Sawyer's flexible support is employed usually, but we saw some double transfer prints having a very pleasant matt surface, due to the employment, as a temporary support, of a sheet of matt opal glass coated first with wax.

From the carbon-printing department we go into the "House," a private house, once the residence of Mr. Sawyer, but now absorbed into, and fully occupied by, the works. In one part we find photogravure being carried on, Messrs. A. E. Smith & Handford, winners in the recent photogravure competition at the Society of Arts, being busily engaged here. Carbon transparencies are, of course, employed, and, to relieve the main works, a building is now being fitted up for the purpose of transparency-making only. In this building, as well as the photogravure department, we find the manufacture of dry plates being carried on, as well as of platinum paper. This is the most recent enterprise of the Autotype Company, and is progressing healthily. We saw a number of specimens on papers of various degrees of roughness, from some thick lines, with a beautiful ivory-like surface, down to a very coarse Creswick, both in black and in sepia tints. Space forbids us from giving to these departments the attention they deserve. For the same reason we cannot do more than refer to the collotype department, a very old-established portion of the works, collotype having been done here since 1870. There is much also to interest the spectator in the many minor operations which are carried on in the Ealing works. The enamelling of paper, the manufacture of pyroxyline, the rolling of prints and papers for collotype, and many other matters attract attention in walking through the works, but can only be alluded to here.

In conclusion, we would remark that the works are compact and well built. Their numerous departments are, doubtless, arranged with a view to business convenience and the due sequence of operations, but at a cursory view are quite bewildering in their number and connexions with one another, and everything shows signs of a large business being done, and that of a good class. The situation for this purpose is an excellent one, plenty of light and of fresh air, and a good supply of water being available. The Autotype Company has taken its place as one of the great enterprises of photography.

ASTRONOMICAL PHOTOGRAPHY.

In this week's JOURNAL you ask any of your readers who know, to give a querist information as to the above. As an amateur, I have done a little that way. The size of an image of the moon in any telescope is, according to M. Flammarion, one hundredth part of its focal length. In a telescope of forty-eight inches' focus, such as your inquirer possesses, the image of the moon at the principal focus would be barely five-tenths of an inch. As a sixpence is three-fourths of an inch in diameter, you can easily see how small the image would be. As regards the amount of light, a telescope of forty-eight inches' focus and four inches diameter would give a practically instantaneous picture of the moon. My own instrument is an eight-and-a-half-inch silver-on-glass reflector of seventy-seven inches focus, with the flat silvered, but with the large mirror unsilvered, that is, only plain glass, I get an instantaneous picture of the moon nearly eight-tenths of an inch in diameter. I have enlarged some of these up to one and a half inches, and they show a good many of the leading features of the moon very well.

Dr. Steinheil, of Munich, has shown that plain glass only reflects five per cent. of the light falling upon it, while a recent experimenter has made it only three per cent. The proportion betwixt a four-inch and an eight-and-a-half-inch is as sixteen to sixty-eight; but, to get the effective intensity of light affecting the plate in the two cases mentioned, we must divide sixty-eight by twenty, thus reducing the effective aperture of my reflector numbers to a glass equivalent to one 3·4 inches in diameter. I used no shutter. I just placed my cap between the flat and the eyepiece mount and took it away, and replaced it again as rapidly as I could. Of course, your inquirer may get much larger pictures of the moon if he uses a properly corrected negative lens in front of the sensitive plate. In my own case, I have a Zeiss negative lens of three inches' negative focus, such as Zeiss make for tele-photography; but, owing to the moon being unsuitably placed during the summer as regards my window, I have been unable as yet to use it. With such a negative lens I shall be able to get the image of the moon at least one and a half inches in diameter. Of course, the size of the image depends upon the length of the camera used.

There is another point: your inquirer would require his instrument, being a refractor, first of all, to find its actinic focus. This he can do by placing a plate in the attached camera, keeping the telescope fixed, and allowing a star to make a trail across the plate. He should do this with different lengths of his draw tube. On development, the plate will at once show which is sharpest. The plates I used were not rapid ones, but ordinary.

WEGA.

"PHOTOGRAPHY IN NATURAL COLOURS" (?)—A CHALLENGE.

LAST week we had a reference to the alleged discovery by Mr. Bennetto, of Newquay, of a method of taking photographs in the colours of nature. We have received a copy of the *Newquay Visitors' Notes* of July 31, containing the following communication from Mr. G. G. Bullmore, of Newquay:—

A friend of mine has read your article, "A grand discovery by a Newquay photographer" in your last week's issue, in which you state: "After seven years of patient investigation, our townsman, Mr. Wallace Bennetto, has attained what at one time appeared to be an unrealisable dream, viz., photography in colours of nature by *purely* photographic means." This friend is like Thomas of old—faithless and unbelieving," but also, like the said Thomas, is open to conviction. *He has, therefore, placed in my hands the sum of twenty guineas*, which he offers, through me, to devote to the furnishing of a ward in the new Isolation Hospital, if you will produce, within the space of one month, such photographs as you describe, viz., "Of the cliffs against the electric blue of the sea, varied by sea pinks in full bloom; or a sunrise and sunset," on the conditions that, should you fail to do, so you will pay the sum of 20*l.* to a similar object, and present a bound volume of the *Newquay Visitors' Notes and Directory*, containing a copy of last week's issue, to the British Museum.

You have stated that "several leading scientists and distinguished persons have seen the results and have declared them marvellous." It may shorten the issue if you will give their names, but, if I should not be satisfied that they are qualified to give an expert opinion, I am willing to abide by the decision of the Editor of THE BRITISH JOURNAL OF PHOTOGRAPHY.

Personally, I am anxious that some public institution may be thus benefited, and I presume, on again reading your article, there should be no difficulty in accepting the offer through your columns in the current issue. Of course, before the matter is proceeded with, the two amounts must be deposited with some disinterested person to be mutually agreed upon.

Our contemporary states that an announcement concerning Mr. Bullmore's offer will probably appear in its next issue (August 7).

IMPRESSIONISM AND REALISM: THEIR SCOPE AND LIMITS IN PHOTOGRAPHY.*

REALISM.

HAVING endeavoured to give a clear idea of what is meant by impressionism, I will proceed to define realism. This will not be so difficult, because the term is narrower in its scope, and by its nature more readily admits of exact definition.

Dr. Emerson defines realism as "the sharp photograph—wherein sentiment, illusion, and decoration are disregarded; merely a register of bald facts mathematically true." In another place he adds: "For example, the realist, if painting a tree a hundred yards off, would not strive to render the tree as it looks to him from where he is sitting, but he would probably gather leaves of the tree and place them before him, and paint them as they looked within twelve inches of his eyes, and, as

* Concluded from page 460.

the modern pre-Raphaelites did, he might even imitate the local colour of things themselves." Another definition, by the Rev. F. C. Lambart, runs: "The Realists aim at a faithful presentation of nature as opposed to expression of abstract ideas. Perhaps the Dutch School carried this method out most thoroughly, and painted a cat or a fiddle," as Reynolds said, "so that you could take it up." This slavish imitation of the Dutch painters was their chief trait. They copied objects exactly as they appeared in every respect. There is a curious example of this in a portrait of a gentleman in the National Gallery. We see a middle-aged gentleman without his hat, the lower part of his face ruddy from exposure to the air and sun; his forehead, having been shaded by his hat, is white, with the exception of one red band caused by the pressure of his head gear against the skin. To depict such a mark is the essence of realism, the realism of accidents. As F. C. Robinson remarks, "There is the Mr. Bounderby of photography, who must have facts, and nothing but facts." Near to this portrait of a gentleman hangs a landscape with figures, which carries out the "facts and nothing but facts" ideal; in this picture every leaf in a tree is accurately reproduced, and we marvel at the patience and industry of the artist who could paint objects with this microscopic care. This is the realism of essentials. Ruskin also classes the pre-Raphaelites with the realists. He says their aim was "to paint things as they probably did look and happen, and not as, by rules of art developed under Raphael, they might be supposed gracefully, deliciously, or sublimely to have happened." To sum up, realism may be pithily described as "fidelity to nature or to real life; representation without idealisation, and making no appeal to the imagination, adherence to the actual fact."

From a study of these attempts to fix the meaning of the ideas we attach to the terms "realism" and "impressionism," it will be readily seen each stands for a distinct phase of art; and, furthermore, that they are contradictory. Each is possible only by the suppression of the other. Impressionism gains its effects by the neglect of form, colour, light and shade, striving to give the motion or vitality of the subject; realism depends solely on form, colour, and, in a less degree, on light and shade, leaving aside all attempts to impress the spectator with the idea of motion. It is at once perceived to be ridiculous to show every hair on a running dog, every feather on a flying bird, or every fibre of a flower bending with the wind, and such motion cannot be depicted on canvas, but only suggested to the imagination by an impression. This opposition between realism and impressionism will be still more marked in discussing their scope and limits in photography.

Impressionism: Scope.

The scope of impressionism in photography is very contracted, mainly due to the chief purpose it seeks to carry out, that of representing motion—a thing less possible in the photograph than the painting. The photographic impressionist, to practise his method, must suggest motion by want of sharpness or "fuzziness," as the painter does by indefiniteness of outline, weakness of form, and obscured detail; but, in the photograph, the limit of such a process is quickly reached in the destruction of the structure of the image which takes place. The painter, however, can go much beyond the photographer, and retain his form amidst a very indefinite outline. Thus, compelled by this necessity, we see that the most prominent feature in the work of photographic impressionists is the disregard of sharpness, and, as in the paintings, every phase is subjected to the general effect, the result being that it throws out the immaterial or imaginative qualities of the work at the expense of the material and actual. The soul, or want of soul, is laid bare. A photographer can thus, to a certain extent, take advantage of impressionist treatment to animate his works with the quality of life and movement.

Another power which impressionism gives to the photographer is that of suppressing some portions of his pictures and giving prominence to a few beautiful and striking features. In this connexion I will quote Edward Dunmore, who has pointed this out very clearly. He says: "*Sometimes* a fuzzy, out-of-focus picture possesses very many art qualities, and has very great charms for a true artist, whether he is a photographer or not; but the charm does not lie in the fuzziness, but in certain leading beautiful lines, which are emphasised by all minor or less important ones being suppressed or indistinct." In technical language, this is the quality of broadness, that simple and wide treatment of light and shade, which is wanting in so many photographs. Spottiness of light and shade is a standing defect of camera pictures, and impressionism certainly supplies the remedy to cure this ill.

A third lesson we may learn from impressionism; and the most important, not only to photographers but to artists generally, is the doctrine of the relative values of tones. This should be carefully examined by all photographers, and the works of impressionists studied diligently. This doctrine is in no way necessarily confined to impressionism, but can be applied independently to any method of pictorial art. In general, partly inherent in defects in the chemical process, and partly through lack of knowledge, the photograph wants harmony of tone with nature. This failure to yield a pleasing and natural gradation of tone can be seen in many of the reproductions from the National Gallery paintings. They entirely failed to give the values of light and shade and atmosphere of the originals. Take, for example, Rembrandt's picture of himself; the original is a marvellous rendering of light and shade, and yet in the reproductions, although good copies photographically, it comes out harsh and crude. This may, of course, be due to the colour scheme of the original; but, whatever the cause, the reproduction cannot for one moment be compared with the painting. As a rule, photographs are too dark in the shadows, and too light in the half-tones; hence a gap in gradation occurs. This being a general fault, it would be far better to work within a narrower range of tones, instead of from black to white. In all sunlit photographs the shadows are too black, and altogether too intense as an impression received from nature; these shadows, being so deep, throw out of harmony the remainder of the subject. How can this be remedied? It will always remain a standing difficulty; for, if we expose for the shadows, in the mean time the lighter tones have lost their proper relative value; therefore with such a subject we may over, under, or correctly expose, each time obtaining a different tone value, and each time a false value to nature. An idea has occurred to me, in looking over some portraits of ladies' wearing veils, which might be utilised to lessen this heaviness. I notice in these prints that, where the veil covers the hair, there the shadows are much more harmonious. Now, it would be possible, by using a gauze curtain in a particular position, to break up the shadows throughout a photograph by a similar method, and yet show no grain. Such a process is daily used for obtaining a decided grain for photo-mechanical work, but I have never seen it suggested for the above purpose. It would be worth trying to lighten heavy shadows.

The foregoing three points indicate the leading merits of impressionism, and all are especially difficult to practice in photography.

Limits.

The limitations of impressionism in application to photography may be shortly stated as want of form, detail, reality, mind, and by its being tied to nature.

The great artistic defect of photography is its want of colour, hence it must gain its results either by form or light and shade. The impressionist takes away, or rather subordinates, form, colour, and light and shade to motion, so that the photographic impressionist, without colour, is left with form, light and shade, and motion in which to express himself. But form tends to vanish in motion; thus ultimately he is driven to the single power of light and shade in which to obtain his effects. And this, as I have shown above, is a false and often untruthful means of expression by photographic processes. Thus the photographic impressionist, without colour, deliberately sacrifices form, the next strong power of delineating objects; he therefore weakens his power of representing inanimate objects in which form predominates. A house to be truthfully depicted does not want the attribute of life which is the main end of the impressionist to create, though such a treatment will undoubtedly suit clouds, trees, or animals, which are in the same picture. The house, in losing its correctness of form and the clearness of detail, becomes shadowy, unsubstantial, and weak. This will be found to be the character of the houses in Walker's picture; they are not real houses, but ghosts. The loss of form and detail in things which are by nature solid and real, means a want of reality. Thus the impressionist, whilst gaining the reality of trees and flowers, loses the reality of solid things. This vagueness of solid objects creates a feeling of want of mind, for it is only by the exercise of reason and our mental powers that we can conceive of solids at all. Solids do not impress us at a glance, but rather by analysing the form and carefully noting the detail; it is a process of judgment combined with simple perception, and takes time; hence, to give an idea of solidness, the picture must also be built up bit by bit in the observer's mind, and not impressed in a flash. Lastly, this want of mind is mainly the outcome of the contracted sphere of nature in which the impressionist is content to work. Robinson noticed the narrowness of the impressionist's interpretation of the term "nature," it practically excludes man and his emotions. This deficiency of impressionism was noticed as early as the days of Velasquez; a writer of that period observes: "The naturalist is a mere reader, who cannot think beyond what he finds in the book (of nature)." On the other hand, the true artist is a thinker, a dialectician,

who argues, demonstrates, disproves and concludes with his pencil. When impressionism goes beyond its own conception of what constitutes nature, it is not to be compared with other pictorial methods; this I can better illustrate under the scope of realism.

Realism: Scope.

Realism is of much greater value to the photographer than impressionism, because it upholds the supremacy of form and definition. The photographer should never release his grip of form and detail, for they are the richest and most fruitful art sources under which he can work. Form combined with light and shade is the proper sphere of the photographer, and, if he work with the spirit of an artist, he will produce pictures having a just claim to be regarded as fine art. Under realism it is possible to express more of the attributes of nature than under any other artistic method. The impressionist can only gain his end by sacrificing some of the advantages of realism that he might use. In a realistic work we gain what we lose in an impressionistic, that is, form, detail, reality, and, as a consequence, an evidence of mind and a fuller, richer, and more interesting picture of nature. The scope of realistic photography is wider than any other manner, its limits are consequently fewer; in addition, it is not confined to palpitating nature, but can roam at will through every field of art. There is one sphere totally ignored by the impressionist, thus admitting that it is without the bounds of his art, yet which comes well within the range of realism, I refer to the picture with a story to tell; such a thing is almost impossible to the former, hence his disdain, but it is peculiarly adapted to the latter. Thus every picture with a story to tell is painted realistically. Take for instance, *Choosing the Wedding-gown* by Mulready. What could the impressionist make of such a subject? The very question reveals the limitations of impressionism; human emotions are beyond its sphere, they partake too much of the internal above the external. That is to say, in such a picture, the subjects must be drawn as "real persons in a solid world—not of personifications in a vaporescent one," and painted after the fashion of the realist, who works from the cause to the effect, and does not let the effect reveal, and perhaps hide, the cause. Subject pictures are very complex, the mind must first analyse them, and then put them together again before they become intelligible. Hence, in building them up, the mind experiences the emotions which the various parts of the painting express, and a direct appeal is made, not only to the eye, but also to the mind. Now, it is not possible to project ourselves in this manner into an impressionist work; their unity prevents it, and they give the mind no support. The *Harbour of Refuge* certainly arouses the emotions of the spectator, I have tried to ascertain from whence this arises, but am still in doubt. It is not the subject of the picture, but probably the association in the mind of the declining sun and the declining days of the aged; perhaps it is caused solely by the reproduction of sunset, in any case it is the eye, and not the mind, which is chiefly addressed.

Impressionism appeals mostly to the eye; realism, bringing in more thought, acts more upon the mind, and in so doing, establishes its superiority; realism is thus a richer art and can express more of the beautiful than impressionism. As Sir J. Reynolds remarks: "It is not the eye, it is the mind which the painter of genius desires to address. Realism, we may therefore conclude, is the larger art, it is more in agreement with photography, and better adapted to bring out the special qualities of the camera products; hence photographers should use it the more largely, remembering that its merits are form, detail, reality, mind, and a wider scope. Nevertheless, it must not be forgotten that impressionism can be successfully used upon such subjects as I have pointed out, and cannot be surpassed to give simplicity and broadness of effect.

Limits.

The faults of realism are that it tends towards woodenness, want of vitality, to vulgarity and the ugly, to place detail before form, and to disregard tone values.

It is obvious, that any method which gives minor detail equal prominence with the larger masses must be wrong, photography is very liable to this mistake. Reynolds pointed this error out in his lectures; he says: "Even in portraits, the grace, and," we may add, "the likeness, consists more in taking the general air than in observing the exact similitude of every feature." This precept he practised in his works. The Dutch, on the contrary, copied every line and every fault in their sitters; their portraits are the more truthful, but Sir Joshua's are the more beautiful.

This fidelity to detail helps to increase the stiffness so common in painters of the realistic school, they suffer from the defect of their virtues. Exact copying of nature leads to slavish imitation, to vulgarity, and to perpetuate blemishes. It also causes painters to place the methods of art before its aims. The cabbage is thus a favourite subject of realists, not because of its beauty, but because it offers an excellent means for the display of technical skill. In like manner, dark interiors are often the subjects of photographers, not for their beauty, but for the display of technical skill. Degeneration soon follows such realists, for they begin by copying the decayed leaves of a cabbage, and end by portraying some horrible object fresh from the hospital. So entirely engrossed by detail is the realist, that he is apt to lose sight of his picture as a whole; the subtlety of light and shade and relative values he thus misses, and still further increases the hardness of his pictures. All these faults can be urged against photography, and they should be avoided as far as possible; but it may be debated whether these defects are not compensated for by the supreme truth which their very presence implies.

Throughout these articles I have made no reference to idealism, because, firstly, it would only have helped to confuse a subject none too clear already; secondly, photographers have still many worlds to conquer in the realm of impressionism and realism; thirdly, it will be time for photographers to discuss idealism, when the men calling themselves artists because they can express idealism, and denying the same name to photographers because they cannot—when such men show this same idealism in their works which is now totally missing; fourthly, whilst the pictorial arts express idealism with the utmost difficulty, other arts express it with ease; and I hold it is best left with them.

Returning to the question with which we started—the influence of impressionism on artistic photography—I will draw the following conclusions:—

(1) That impressionism has aided photography by directing attention to its art possibilities, and by giving it a new method.

(2) It has proved that photography can and does express individuality, even to creating opposite schools.

(3) It has given a means to express the artistic quality of broadness, and pointed forcibly to the importance of tone values.

(4) Taken throughout, it has immensely strengthened the right of photography to the title of a fine art, and raised the artistic merits of its productions.

In conclusion, I would have liked to have supported these assertions by referring to actual works, easily accessible to all; but no such collection exists. That pleasure I must defer until the establishment of a National Gallery of Photographic Art.

John A Randall.

TABER'S METHOD OF PRODUCING EMBOSSED PHOTOGRAPHS.

The patentee, Mr. F. A. Taber, says:—

"Heretofore photographs have been produced on flat paper and rounded or bulged paper, the latter being an endeavour to project the image to give the idea of relief. On the flat paper the same idea has been carried out, in accenting the light and shadows on the image, and throwing an imaginary shadow on the background such as would be produced by a raised image.

"This invention is designed to produce the above-mentioned effect, and consists in forming a mould from a photographic impression from the same negative as used in producing the prints, and then in pressing them into the mould, where they are dried under pressure to the form of the mould.

"The first step in this process is in the taking of the negative, as is usual in photography. A block of wood is then provided with a sensitised surface to receive a photographic impression, which is developed as a plate or paper. In some cases I prefer to merely provide as a sensitised surface for the block a prepared sheet of sensitised paper. This block is then carved out to varying depths, according to the intensity of the lights and shadows on the photograph. In carving, the high lights and pronounced features are sunk the deepest, and from them the remaining carving is graduated. This mould is dressed off smooth to leave no rough surfaces to mar the photograph, and is then ready to receive the print. While I have here described the carving as being minute in details of features, this is not essential, for the reason that the smallest features are shown by the lights and shades of the photograph.

"To register the moulded impression and the print, I provide a form or frame which is the exact size of the print. Within this the print is laid, and must register exactly with the mould.

"The prints are now mounted on a cardboard backing, and when set they are moistened and placed over the mould in the frame face downwards. Sponge rubber is then spread over the back, and the whole placed in a press, which by means of the interposed rubber forces the print into the mould and compels it to take the shape of the mould. This shape being sunk in the mould to the varying depths, produces in the photograph a counter relief.

"The print is now maintained under pressure until dried, when it

will be found to be embossed to conform to the photograph, the features being pronounced in likeness to the individual.

"When so dried, the embossed print is mounted on suitable mounts. In some cases I find it desirable to fill the back of the embossed image with plaster or other material, for the purpose of maintaining it solid. Also I find I can pack them more easily by placing them on mounts with sunken panels, as the sides of the mounts prevent the mashing of the embossed prints."

The patentee's claims are:—

1. The method of producing a photographic image, which consists in transferring a photographic impression upon a block, sinking into the said block a mould for the features in conformity with the photographic impression, placing over the mould a photographic print, and pressing the same into the mould to emboss.

2. As a new article of manufacture, a photographic image, the features of which are embossed.

3. As a new article of manufacture, a photographic image, the features of which are embossed and are packed with a hard material to prevent mashing.

4. As a new article of manufacture, a photographic image, the features of which are embossed and backed with a hard material to prevent mashing, and provided with a mount, the sides of which extend to a level with and above the highest embossed parts.

[It is interesting to compare the above process with a very similar one that has been previously patented, and is described in the JOURNAL of July 24.—EDS.]

POCKNELL'S IMPROVEMENTS IN DARK SLIDES.

MR. EDWARD POCKNELL says:—

"According to one portion of my invention I employ an improved shutter in which the main portion of the shutter can be detached, leaving the bottom part permanently connected to the slide.

"For this purpose, a pull-off hinge or connexion is used, so that the shutter can be pulled to the top of the slide, and then at once detached. The shutter and bottom ledge slide in grooves in the usual manner, the bottom ledge being prevented from moving past the upper end of the slide. This ledge covers the top of the glass, and prevents any danger of light leaking through this part, and thus injuring the plate at the other side.

"The connexion I propose to employ between the shutter and the ledge consists of a small hook on the latter and a corresponding hook on the bottom of the shutter, so placed that the two can engage together when the shutter is in line with the ledge. The shutter and ledge are rebated, and the lower end of the shutter is formed with a recess in its inner face into which the hook on the ledge can extend to engage with the upper hook. Thus, on pulling the shutter to the top, it can be at once detached by a slight motion to one side.

"This arrangement is especially convenient in the case of hand cameras, as it allows the shutter to be completely removed instead of having it lying on top of the camera, or otherwise placed in an inconvenient position.

"Another portion of my invention consists of a simple indicating device fitted to the top of the slide. This indicator is made from a small metal bar or strip furnished with a head and sliding in a groove. The indicator can be moved to either end of the groove, and, according to its position, it will indicate whether the plate has or has not been used.

"To open the slide for insertion or removal of the plates, I employ a small door of metal or rather suitable material hinged to one of the lower corners of the slide and extending across the bottom, a groove being formed to receive it.

"The door is furnished with a small hinged plate serving as a catch, a pin being fitted to the side of the slide to retain the plate. The door is furnished with two narrow ribs or ledges which project into the ends of the compartments carrying the plates supporting the latter and holding them in position.

"To remove the plates, the door is opened, allowing them to fall into the hand."

FAY'S IMPROVEMENTS IN MOUNTING PHOTOGRAPHIC CAMERAS ON THEIR TRIPODS OR SUPPORTS.

MR. JOHN HENRY FAY, of 22, Eastbourne-road, South Tottenham, says that the object of his invention is to provide very simple and cheap, but highly efficient, means for mounting photographic cameras on their tripods or other supporting appliances in such wise that these cameras can very easily and quickly be moved into any position, and be pointed in any direction and be trained on objects or views wheresoever such objects or views may be.

"To carry out this object I place on the top or platform of the tripod or other supporting appliance a table of the desired size and shape, and centrally or thereabouts pivoted thereon in such wise as to be capable of being turned on this top or platform, and of being clamped theron in any position.

"Two parallel plates are made of any desired sizes and shapes, and maintained in any convenient manner a certain small distance apart, and these plates can together be mounted on edge transversely across the table, it may be by a web common to both hinged or pivoted on such table or otherwise in such manner that they can together be erected on this table, and also turned down on both sides until they are parallel with the same or thereabouts. To support these plates in their desired positions a semicircular slotted guide can be erected on the table across one of their ends through which slot can pass a stud or bolt secured on or to this end of the plates, and a screw nut on such stud can clamp the same in position in the slot.

"A lug, or bracket, or the like, is formed on or attached to the camera in any desired position, and may be of any suitable size being capable of being inserted between the two plates, and, when properly placed between the same, a bolt can be passed through the parts to act as a pivot, whereon this lug, or the like, and therefore also the camera, can be turned, and a screw nut on this bolt can clamp these parts in any desired relative positions.

"It is therefore obvious that the camera can be easily and quickly moved on the pivot in the plates, the plates on their hinges or pivots on the table, and the table on its pivot on the top of the tripod or appliance into what relative positions are required, and therein can be securely clamped, and then as easily and quickly be moved into other positions, and so on.

"Instead of hingeing or pivoting the plates by or through their lower horizontal edges on the table as aforesaid, they can be pivoted by the lower parts of their lateral edges, or by prolongations of the same in brackets or the like erected in the proper positions on the table, or, when desired, only one of such lateral edges can be so fitted, whereby the same effects would be produced.

"Again, instead of the semicircular slotted guide aforesaid, a large flat and broad standard can be erected on the table in the same position, and the plates aforesaid can be formed on or secured to a disc or the like by or through one of their lateral edges, and this disc or the like can be centrally or thereabouts pivoted on the face of the large standard on which pivot a screw nut can be fitted to clamp this disc or the like in any desired relative position whereby also the same effects would be produced.

"Although, as a general rule, it may be preferable to provide two plates between which the lug or bracket on the camera can be pivoted, yet, when desired, only one plate may be provided, whereto or whereon this lug or bracket could be pivoted in the same manner. In this case also the lug or bracket on the camera could be duplicated if desired, and could pass on both sides of the single plate.

"In all cases the pivots, the hinges, and the clamping appliances can be made and fitted in any usual and convenient manner suitable for allowing them to perform their necessary functions aforesaid with ease, rapidity, and certitude."

A NEW FRENA CAMERA.

R. & J. Beck, 68, Cornhill, E.C.

WITH the title of the "No. 00" (or memorandum size), Messrs. Beck are introducing a new Frena camera, taking films of the size $3\frac{1}{2} \times 2\frac{3}{8}$, and possessing several novel features which constitute it one of the simplest and most effective little hand cameras that has been shown to us for a considerable time past. The same form of shutter, diaphragms to the lens, the swing back and level, the finders, automatic indicator, and the other features of the larger and more expensive Frena camera have been retained in the memorandum-size Frena, which carries forty films in a pack, as in the other Frena cameras. The operation of changing the film is effected as before by turning the handle round half a revolution and back, but the mechanism of the film changing has been altered.

Fig. 1 shows a side view of the camera To take out the exposed films, the strap handle having been unbuckled, the back of the camera,

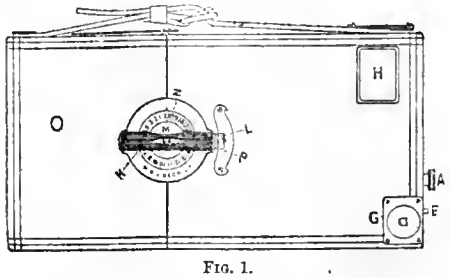


FIG. 1.

C, is removed by undoing the spring catch at the top. The exposed films will be found lying in the back of the camera. It will then be observed that the metal holder which carries the pack of unexposed films, together with the handle, indicator, &c., swings on bearings which fit in semicircular cradles formed by the sides of the camera itself.

This holder may be lifted entirely out of the camera for recharging (figs. 2 and 3). To load the empty camera, a stiff dummy film (fig. 4),

is placed in the holder, the packs inserted exactly as supplied by the makers, and the pressure board snapped into position; the holder is

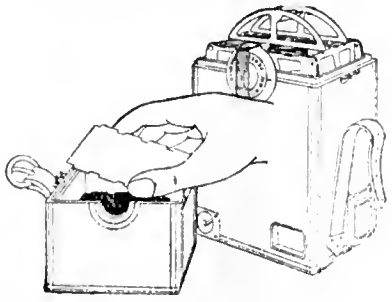

Fig. 2.

then placed in position in the Frena (fig. 2), and the back of the camera snapped on, and the camera is reloaded. The process of changing the film is as follows:—Hold the camera with its lens pointing upwards towards the sky, and grasp the level handle, K (fig. 1), by the ends,

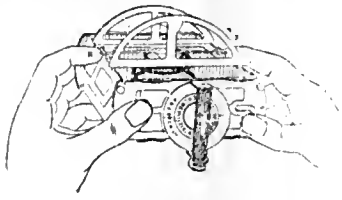

Fig. 3.

which releases the retaining catch; turn it a complete half turn in whichever direction it is free to move, and then return it to its original position. As a matter of fact, the operator will find that each time a

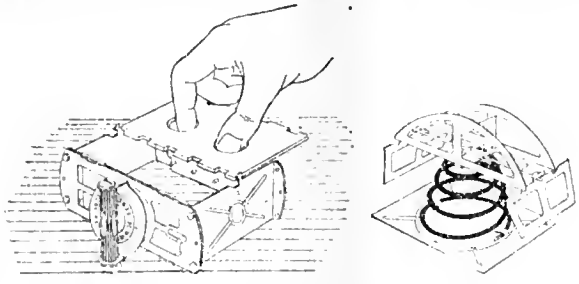

Fig. 4.

film is changed it is turned in an opposite direction, but, as it cannot be turned in the wrong direction, this is no inconvenience.

The camera has a revolving finder, which may be rotated so as to show the exact image that will be photographed in the vertical or horizontal finder hole respectively, according as to whether a vertical or horizontal picture is being taken.

The shutter has five different speeds, $\frac{1}{5}$, $\frac{1}{10}$, $\frac{1}{25}$, $\frac{1}{50}$, $\frac{1}{75}$ second, and also time exposures. For instantaneous exposures the set-off knob is pushed in, and for time exposures the same set-off knob is pulled out, opening the lens, and then pushed in to close the lens. The speed to which the shutter is set is recorded in the lens aperture. The lens is a single achromatic Beck lens, provided with diaphragms operated by a knob on the front of the camera.

The swing back is obtained by simply tilting the holder in which the films are held until the bubble of the level in the handle is central, whatever the angle of the camera may be. This corrects the distortion that may be caused by pointing the camera up or down.

The lens is then stopped down to correct any loss of definition that may be caused by the top and bottom of the film being out of focus. An indicator counts the number of exposures.

The memorandum-size Frena weighs only two and three-quarter pounds, loaded with forty films. It measures $9\frac{1}{2} \times 5 \times 3\frac{1}{2}$ inches.

Results produced by the new Frena are before us as we write, and they are unusually good. The camera is cheap, and from a careful examination made of it we have no hesitation in pronouncing it well made and exceedingly simple to work. It is a step in the direction of making hand-camera work "as easy as shelling peas."

INFLUENCE OF THE RÖNTGEN RAYS ON THE SKIN.

It may, or it may not, be known that the X rays are productive of a serious affection of the skin, if it is frequently subjected to their influence. As a case in point, the demonstrator at Olympia, who has daily experiments to attend to with this force, has his hands, as far as the second joint of the fingers, almost denuded of skin; they appear as if they had been severely scalded, with considerable inflammation and swelling. Suppuration of one finger-end seems to be in progress. Altogether the state of the hands is very painful and unsightly; but with regard to the pain, since the swelling subsided, it has not been much. This is the first case of injury that has been brought to my notice, as I have seen no allusion to it in any publication that I happen to have read, although it is quite possible others may have suffered in the same manner, attributing the affection to something else. Of course, the effects in this case may be owing to something else; but the sufferer, an intelligent man, is perfectly convinced that the Röntgen rays are undoubtedly the cause, and nothing else. On the strength of this opinion I forward you these notes. Edward Dunmore.

Our Editorial Table.

Photography Annual 1896.

Edited by Henry Sturmey. London: Iliffe & Sturmey, 3, Bride-street.

Well printed and got up, as hitherto, the 1896 Annual of our contemporary, *Photography*, is before us. The prominent features of previous issues are retained and some improvements in detail are introduced. Tables of reference, a list of dealers and dark rooms, practical articles, including contributions on X ray photography by Abney, Swinton & Gifford find place in the Annual, wherein also Mr. Bothamley has an exhaustive record of progress in photographic chemistry during 1895; Mr. Chapman Jones so treating of optics and Mr. Bolas of photo-mechanical printing. Rev. F. C. Lambert summarises artistic progress in 1895. He surveys both the Salon and Royal Photographic Society's Exhibitions with an impartiality as refreshing as it is uncommon. Mr. Albert Taylor as usual deals with astro-photography in 1895, and Mr. C. R. Rowe puts a deal of conscientious work into the compilation of the section devoted to photographic apparatus. There are several excellent illustrations from negatives by Mr. Sturmey, Mr. Rowe, Mr. Harold Baker, and others; and, on the whole, the Annual must be pronounced an admirable production.

The X Rays.

By Arthur Thornton, M.A. Bradford: Percy Lund & Co.

Mr. Thornton's great difficulty in the compilation of this little book has obviously been want of space, much of the information he gives being of a very fragmentary nature. Nevertheless, within the limits at his command, he has contrived to give us one of the most interesting little treatises in connexion with radiography that has so far been published. The earlier chapters are devoted to an elucidation of the theories of sound and light vibrations, and the phenomena of electrical discharges. Thence follows a history of the discovery of the X rays by Rontgen, together with a brief examination of the explanatory theories that have since been published with regard thereto. The photographic aspects of the subject next engage attention. Mr. Thornton is concise and clear in his exposition, and shows that he is at home in the practice as well as the theory of radiography.

Shakespeare's Town and Times.

By H. Snowden Ward and Catherine Weed Ward.
London: Dawbarn & Ward, 6, Farringdon-avenue, E.C.

We look forward to the time when this book, which is obviously the outcome of a loving and painstaking study of a facinating theme, shall have secured the matured fame of a cheap edition, for, while in all probability the Shakespearean scholar will welcome it, the very humblest reader of the bard cannot fail to be interested in, and instructed by, the plain tale of the great poet's life and surroundings that it sets forth. Stratford-on-Avon and district are exhaustively described, while the poet's ancestry, childhood, boyhood, youth, and courtship; his struggles in quest of a fortune; his manhood and close of life are dealt with in a series of ably written chapters to which are appended useful information for visitors, a map of the district, Shakespeare's will, and other interesting items. The authors appear to have spared no trouble in research to verify their facts and dates, so that the literary portion of the book has all the stamp of being a thoroughly careful and conscientious history.

From the photographic point of view, the chief attraction of the work lies in the illustrations, of which, in all, there are considerably over a hundred. With few exceptions, no clue is given as to who

was responsible for the original photographs, but it is safe to conjecture that these are the work of Mrs. Snowden Ward, whom we know to have passed much time at Stratford with the camera. Without exception, the photographs, depicting scenes in and about Stratford—old houses, memorials, streets, churches, monuments, tombs, interiors, copies of paintings, land and river scapes, statues, portraits, mostly suggestive of or conveying an idea of the surroundings of the poet and Anne Hathaway in the spacious sixteenth century, have been admirably executed. Indeed, some of the interiors, for technical and artistic excellence, would be difficult to excel. The illustrations are in half-tone by the Swan Engraving Company, and are qualitatively above reproach. Messrs. Allen & Carruthers, the printers, of Chiswick, have turned out the volume in faultless style; paper and type have been well selected, and we should like to pay a special compliment, rarely accorded, to the makers of the inks used—Messrs. Shackell & Edwards—who have enabled the fullest justice to be done to the exquisite blocks and typography.

All concerned, and especially the authors, are to be congratulated on the production of a book in every respect worthy of its great subject, and which deserves to secure a permanent place among the literature devoted to William Shakespeare.

News and Notes.

Slum-life Photography.—This month's *Quiver* leads off with a brightly written and telling article on the inhabitants of Slumland by Mr. Hector Maclean. Of special interest to our readers are the illustrations, which have been reproduced from photographs by Mr. Edgar Scamell. Although the printing and paper of the magazine hardly do justice to the blocks, a liberal amount of line and hatch has been put in by hand, which, although photographic purists may object, certainly helps to give vigour and finish to the half-tone reproduction. The above clever collaboratioo of photographer and writer is an example which might with advantage be followed.

I entirely dispute the contention that the lantern is in its decadence. Its possibilities are only being recognised, and whether as the adjunct of the scientist or the explorer, or simply in embellishing the text of the entertainer, lantern slides will ever be in demand by the lecturer. It is only when the lantern is abused that spectators tire. There is surely nothing so wearisome to the eye and brain as the rapid passing through of a stream of "linkless" pictures one after the other, with no description beyond the bald announcement of the name of subject. What is required is a lecturer who can appeal to his audience through the force of his periods, and heighten the interest of his subject by the illuminated examples he throws on the screen before them. —*Journal of the Photographic Society of India.*

German Glass Industry.—According to the *Hdndels Museum* the glass industry of Germany can be divided into two groups, the one including works which produce glass out of the raw material, while to the second group belong those factories which receive glass from the former, and improve it by blowing and cutting At the present time there are 312 actual glass manufactories in Germany, with 50,000 *employés*. In these factories glass and glass wares are produced for consumption, such as bottles and other hollow glass, mirror, and window glass. Of these factories, 187 are in Prussia, 54 in Bavaria, and the remainder in the other German states. To the second group of this industry belong 163 establishments, with 9000 *employés*, so that the total number of factories producing and improving glass in Germany is therefore 475. Of these, 241 are in Prussia, 108 in Bavaria, 33 in Saxony, and the remainder in the smaller German states. The glass industry of Germany has to contend against a very keen competition with Austria-Hungary, Belgium, and France —all these countries, owing to advantages obtained by their commercial treaties with Germany, being able to import into the latter country large quantities of glass and glass wares.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

August.	Name of Society.	Subject.
10.....	North Middlesex	Technical Meeting.
11.....	Birmingham Photo. Society ...	Exhibition of Competition Pictnres taken up in the Excursions to Arbury, Compton Wynyates, and Stokesay.
12.....	Photographic Club	Members' Open Night.
15.....	Borough Polytechnic	Excursion: Streatham and None-such Park.
15.....	Croydon Microscopical	Excursion: Nutfield. Leader, A. Roods.
15.....	Darwen	Excursion: Laugho and Dinckley Ferry. Leader, James Cooper.
15.....	South London	Excursion: Ockshott and Esher. Leader, J. T. French.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

July 30,—Mr. R. A. Hodd in the chair.

The Hon. Secretary recounted some tests he had made with a view to ascertaining whether the peculiar markings on negatives brought up and discussed at the previous meeting might be attributed to some action of the material used for the hinges of the slides, or the varnish used for blackening their interiors. A portion of the hinge stuff was put in contact with the plate, and some of the black smeared on the slide ; but, although development was forced until fog set in, no trace of an image was found. Two further exposures showed nothing of a retarding or accelerating action, and the negatives were practically perfect. It may be due, as suggested, to the acid state of the glue. It was thought that the exposures had not been sufficiently long, and that the plates should have been left in the slides for fifty hours, so as to compare with other tests.

He further drew attention to a note in The British Journal of Photography on the roller-blind shutter, in which Dr. Krügener compares the use of this form of shutter immediately in front of the plate with one used in front of the lens. He finds that the shutter in front of the lens is quite as effective as when used in front of the plate. The Hon. Secretary thought this was rather anomalous.

Mr. J. E. Hodd opened a discussion on

Under-exposure, and how to make the most of it.

Granted that the appearance of an under-exposed negative was known to all, he considered that the retention of the normal developer, trusting to additional alkali to finish the development, was very unwise, resulting generally in fogging the whole plate, without improving the shadow detail. Tentative development only was reliable. He did not consider that any of the newer series of reducing agents, used alone, were superior to pyro, with the exception of glycin, although, *in combination* with pyro, some of them were valuable, rodinal being the best. The following formula has answered well :—

1.

Pyro	1 ounce.
Potassium metabisulphite	¼ ,,
Water to	9 ounces 1 drachm.

2.

Potassium carbonate	1 ounce.
Sodium sulphite	½ ,,
Water to	10 ounces.

3.

Potassium bromide	1 ounce.
Water to	10 ounces.

For a normal developer, take of pyro solution 20 minims, alkali 2 to 3 drachms, bromide 5 minims, in which a correct exposure should begin to appear in from thirty to fifty seconds ; but, if the time of appearance is much in excess of this, a fresh solution, composed of pyro solution 10 minims, alkali 1 to 2 drachms, bromide 5 minims, should be substituted, with the addition of five drops of rodinal per ounce. Glycin was found to be a very fair developer with under-exposures, and there was no tendency to fog. As regards a preliminary soaking in alkali, he considered it increased the chances of chemical fog and trilling, and preferred the application, locally, of rodinal for bringing out detail. An improved negative may often be obtained by making a transparency, developing for detail only, and from that a second negative. A coat of matt varnish, tinted, if necessary, with aurantia on the glass side, will be found to strengthen the shadow detail, that on the high lights being scraped away. A matt chloride paper would suit this style of negative.

Mr. Henderson, with reference to time of appearance of the image, said the gelatine films of no two batches of plates were equally hard or soft, and one would take, say, a minute against a few seconds in the other case. If the plates were previously thoroughly soaked in water, the rule might apply. As regards the treatment with alkali first, if there were a small quantity of bromide, mixed with the alkali instead of fog, you would get clearness. He recommended bleaching the negative with bichloride of mercury and exposing to light, when a great improvement would be noticed. In reply to a question, he advocated soaking in water, provided it be pure. Although development did not start so soon, it caught up later, and did not take any more time in the end.

Mr. Mackie recalled a statement that the speed of the plate would be increased by treatment with an alcoholic solution of caustic potash before exposure. He had subjected one-half of a plate to this solution, and on flowing on the developer the portion treated flashed up immediately, but by the time sufficient density was obtained he could not see a dividing line, and it appeared as if not treated at all. There was no hard-and-fast rule as to developing. In the case of a very rapid plate of 200 Hurter & Driffield and an ordinary plate, both proportionately under-exposed, he would, in the latter case, put on the alkali first and add the pyro gradually, but this would fog the fast plate.

The Hon. Secretary found that the activity of the developer was greatly increased by the use of warm water up to about 80° or 90°, and preferred that to adding ammonia.

Mr. Teape thought there was an unnecessary fear of getting fog. He always developed under-exposed plates until they did fog, and thought they were better for it and printed softer.

The Hon. Secretary mentioned that hypo, if added to pyro developer at starting, was said to have no effect, but, if added when the plate was half developed, it helped the detail out.

Mr Banks agreed that preliminary soaking in alkali was beneficial, but it should not be in the form of ammonia. Carbonate of potash or soda would do.

PHOTOGRAPHIC CLUB.

JULY 29,—Mr. E. W. Foxlee in the chair.

The CHAIRMAN welcomed Mr. Charters White, a former member of the Club, to the meeting, and asked him if he had any matters of photographic interest to mention.

Mr. WHITE said that recently he had been doing as little work in his dark room as possible, as he disliked the extreme heat. His photographic work, however, was principally

HISTOLOGICAL WORK WITH THE MICROSCOPE.

In dealing with some of the technical details, Mr. Charters White said that he found a convenient developer to be of prime importance. He had been for some time, and was now, using "Hintokinone," a one-solution developer, which, in his hands, was exceedingly useful and efficient. It gives clean, bright images, and will not stain either the fingers or the plate. Mr. White said that he always gave a full exposure, and then treated the plate to a careful development. Should he find the exposure to be more than sufficient, he diluted his solution, and perhaps added a little bromide; if, on the contrary, under-exposure were present, he should strengthen up his developer from his stock solution. The Hintokinone is a concentrated solution, which has to be diluted with ten times its bulk of water for use.

Mr. NESBITT said that he was glad to hear of any developer which was simple in character and at the same time did not involve the use of the caustic alkalies of potash or soda, to both of which he had a strong objection.

Mr. BRIDGE said that, with reference to Mr. Charters White's remark about diluting the developer to remedy over-exposure, Mr. Alexander Cowan had proved to his own satisfaction, and he thought to that of many members of the Club, that dilution of the developer did not affect the final result.

Mr. FRY said that that was so, but that, as the result was considerably delayed, ample time was given during the operation to select a suitable moment for closing the act of development, and thus a variety of results might be obtained. He added that he thought the statement that no alteration would be effected by the dilution or concentration of the developer must be taken as only obtaining within certain reasonable limits, because extreme dilution tended to give a feeble image, however protracted the action might be, and *vice versâ*.

A member raised the question whether in the experiments and paper read by Mr. Haddon before the Convention the use of silver paper upon which no printed image had been made would be on all fours with similar experiments in which the actual printed image was used. He, the member in question, had a weakness for the actual tests which took place in the workroom. He asked for information, and not in a querulous spirit, as to whether some chemical or physical difference might not make a practical difference between the two sets of conditions.

A general discussion upon the alleged superior stability of the old-time silver prints, the value of gold toning as an aid to permanency, and other analogous subjects of interest to photographers, took place.

Mr. CHARTERS WHITE promised at an early date to give the Club a Travellers' Night. He would show a selection of his Swiss views, of which he was anxious to have the opinion of his old friends of the Club.

South London Photographic Society.—At the last meeting of this Society, held at Hanover Hall, Hanover Park, Peckham, S.E., Mr. W. F. Slater (Vice-President) in the chair, Mr. ALBERT HILL attended, and gave a demonstration of

CRESCO-FYLMA NOVELTIES.

He first dealt with intensification with uranium. The intensifier as at present sold is in an improved form, and is free from the disadvantages of the earlier formula. A negative which is too thin, but free from fog, is simply placed in the solution and left until it is sufficiently built up. If it is afterwards desired to discharge the intensification, and it is unsatisfactory, it can be removed by placing the intensified negative in an alkaline solution, which removes the colour. The negative can, after washing, if desired, be intensified. Local intensification can be performed by applying the intensifier with a brush. Portions of the intensification can be locally removed by the use of a solution of ammonia (one in ten), which removes the colour. The intensifier can also be used for lantern slides, but only red colours can be obtained by its use. The Argura paper, recently placed upon the market, is coated on Whatman's drawing paper, with a large percentage of silver, in order to get a good image. The toning solution is used weaker than with other paper. A good sepia-like tone can be obtained by simply fixing the print in hypo, and, after washing, drying it. No notice should be taken of the colour of the print as it comes from the printing frame. Prints can be waxed by rubbing the surface with a solution of beeswax, dissolved in turpentine. Prints on this paper contrasted favourably with others made on matt-surface papers from the same negatives. The shadows were more transparent. Mr. Hill brought before the notice of the members present some experiments he had been making in the direction of photo-sculpture. He had used bichromated gelatine, and, after printing, fixing it to a glass plate, immersed it in a cresco-fylma solution, which caused the gelatine to expand vertically. Some casts obtained from negatives made in this way were shown.

Patent News.

THE following applications for Patents were made between July 20 and July 25, 1896:—

No. 16,080.—"Improvements in or relating to Apparatus for Taking, Viewing, or Projecting Photographic Images in Rapid Succession to give a Life-like Effect." W. R. ROUTLEDGE, A. ROSENBERG, and W. MCDONALD.

No. 16,303.—"Improvements in Actinometers." C. F. WYNNE.

Correspondence.

☞ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

THE NATIONAL ASSOCIATION OF PROFESSIONAL PHOTOGRAPHERS.

To the EDITORS.

GENTLEMEN,—Will you kindly insert this refutation, in your next weekly issue, of a series of unfounded statements which appeared in a photographic monthly of August?

Referring to the Leeds Convention Meeting of the National Association of Professional Photographers, after stating that this Association "*received its death there*," it was stated that there was proposed "a motion that the Secretary be requested to resign, and, this being carried, he promptly left the meeting . . . ., which then closed."

There is not a word of truth in the foregoing statements.

Mr. Barry (Chairman and President), Mr. T. Fall (Vice-Chairman), Messrs. Harold Baker, A. Freke, and other photographers, well known to the profession and to the Convention, were in Leeds all that week, and easily accessible for inquiry and information.

The headquarters of the National Association of Professional Photographers (the Imperial Hotel, Leeds) were publicly advertised in THE BRITISH JOURNAL OF PHOTOGRAPHY, were publicly posted in the Convention Rooms Office, Leeds, and in the halls of the five hotels named in the Convention programme.

Moreover, a full and lengthy report of the proceedings of this Association was published in THE BRITISH JOURNAL OF PHOTOGRAPHY of July 24 and *Photography* of July 23, &c., wherein it was announced that the *next meeting* of the National Association of Professional Photographers would be held in London, on the Monday after the opening day of the Royal Photographic Society of Great Britain in September next.

The Leeds Convention closed on July 18, a fortnight before the publication of these unfounded statements.

It is to be regretted that, with such ample means of ascertaining the truth, a series of unfounded and misleading statements should have been promulgated in a *monthly* periodical, wherein the *amende honorable* could not possibly appear for another month.—We are, yours, &c., D. J. O'NEILL, *Secretary*.

47 *Charlotte-road, Birmingham, August* 4, 1896.

THE W. H. HARRISON APPEAL.

To the EDITORS.

GENTLEMEN,—Will you kindly allow us to publish a final account of the Fund raised as a testimonial to Mr. W. H. Harrison, and to express the thanks of the recipient and his family to all the friends who have so generously contributed to the fund.

The total amount of the subscriptions is 105*l*. 4*s*., and after deducting 6*l*. 11*s*. (cost of stationery, printing appeals, &c.), there remains a balance of 98*l*. 13*s*., of which 25*l*. has already been handed over to Miss Harrison, in whose care Mr. W. H. Harrison remains.

The balance of 73*l*. 13*s*. is now held in trust for Mr. Harrison, and will be paid over in monthly instalments of 2*l*. to Miss Kate Harrison, for the benefit of her invalid brother.

Should Mr. Harrison recover during the next three years sufficiently to be able to manage his own affairs, the balance remaining unapplied will be handed over to him, or, in the event of his death, to his sister. These arrangements have been made with the approval of all those most closely concerned.

Any further donation received will be added to the fund to be applied in the same manner.—We are, yours, &c., FREDK. H. VARLEY, ANDREW PRINGLE.

COLOUR PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—Under Ex Cathedra, I read with interest about Mr. Bennetto's colour photography. I also note your remarks as to how he does not let a photographer see it. I have not seen any result although living so near, but wish to inform you and the photographic public, that Jane's Colour Photography is not dead or done out, and that photographers and scientists are allowed to see, handle, or have in their private possession, upon signing a form of receipt of same. I am obliged to be cautious as to this, as one good gentleman to whom I sent about twenty of my best specimens has not returned them, and, upon inquiry, I find he has crossed over somewhere. This has caused me great inconvenience and loss of time; this, along with other obstacles, and attention to business, has compelled me almost to abandon my

process for the time. I hope to get something in the Royal Exhibition. I will further confirm my previous statement, that in my process there are *no dyes used*.

I regret I have to sign my name plain "Arthur Jane," and have not a few links or coupling chains at the end of it, so that any that might be able might lay hold, and help on a bit. I have experienced enough buffers, but had very few couplers from the photographic world. Possibly it may not be (scientifically) blended to suit the water of the district.

"Unfinished—I declare it;
Rebuffed—I'll bear it."

I am, yours, &c., ARTHUR JANE.

Crockwell-street, Bodmin, August 1, 1896.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & Co., 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:—

Thomas Arthur Moryson, Dumfries, Scotland.—*Four photographs of the Right Rev. Dr. Turner, Lord Bishop of Galloway, Scotland.*

RECEIVED.—E. S. HODGSON; E. HARRISON; W. HAMPSON; W. BENNETTO; and others. In our next.

ALBUM MAKER.—LUX. Lowthime, Lamb's Conduit-street, W.C., will probably meet your requirements.

SPOTTY PRINTS.—T. W. There is very little question that the spottiness arises from the bronze powder with which the mounts are lettered and edged.

LENS.—J. MCKENNON. A single lens will do quite as well for general landscape work as a double combination. Indeed, some of our best workers prefer that form, for that class of subject, to any other.

FERROTYPE PLATES.—E. MORGAN says: "Will you kindly inform we where I could purchase the dry ferrotype plates, also the gilt frames for the same?"—In reply: Of Fallowfield, 146, Charing Cross-road, W.C.

ETHER FOR COLLODION.—A good quality of methylated ether will do quite well for collodion for the wet process. Methylated alcohol, however, as met with commercially, will not do. The unmethylated alcohol is necessary.

TILTING THE CAMERA.—S. STEPHENS. The print shows that you tilted the camera to get in the whole of the structure, but, at the same time, you neglected to bring the swing back into use. If the camera be tilted, the swing back must be used.

YORK MINSTER.—W. W. H. Conventioners were accorded special privileges on their visit to the cathedral town. No doubt, similar facilities are to be obtained by others by application to the proper authorities, but we are, for the moment, unable to say who they are.

PATENT.—R. M. C. You can certainly patent the camera stand, the same as you can anything else, but the patent would not be valid, because the thing has been done before. Indeed, that form of stand was introduced many years ago, and has been superseded by the different forms now on the market.

PHOTO-MICROGRAPHY.—C. THORNTON. We should certainly advise you not to commence with high power. Make your first essays with, say, a two-inch or an inch-and-a-half objective, and attain to good results with that before going higher. With the quarter and eighth of the maker mentioned you will not be troubled with a "chemical focus."

VALUE OF LENS.—C. A. S. We do not undertake to value apparatus, therefore we cannot say what the lens is worth. We may say, however, if it is by the maker whose name it bears, it would be very cheap indeed at the price mentioned, supposing it to be perfect. Before paying the whole of the sum, we should advise you to show it to the maker, who will advise you as to its genuineness.

LANTERN SLIDES.—S. W. OWEN says: "I shall be obliged if you can inform me what are 'photo relief print' lantern slides? I have purchased some slides second hand, and they have that title printed in gilt letters on the mask. They look rather like Paget printing-out slides, or, at any rate, as if they had been toned."—In all probability the slides are produced by the Woodbury process.

ENCAUSTIC.—S. asks: "What is meant by encausticing prints, which, I am told, used to be done to make them more permanent, as well as improve their appearance."—Practically, it was polishing the prints with beeswax, after the manner that furniture is polished. A little of the compound is rubbed over the picture, and polished off with a piece of flannel. A formula for the "encaustic paste" will be found in the ALMANAC.

REMOVING RETOUCHING.—T. MINNS says: "I sent some negatives to one who advertises to do retouching, but the work is so badly done that the negatives are spoilt as they are. Is there any means of removing it? I am afraid to use indiarubber, for fear of injuring the films."—Supposing the retouching medium used was of the commercial kind, the work can be cleaned off, without injury to the film, with a pledget of cotton-wool charged with turpentine.

SALTED PAPER.—C. H. says: "I have salted some drawing paper by immersion, one white of egg, one ounce of common salt, twenty ounces of water. Result, very unsatisfactory; looks as if it were 'unsalted.' Can you give me a better recipe?"—We should say that paper so treated would bear evidence of being *very* much over-salted. We should advise our correspondent in his next essay, if the paper is immersed, to use a quarter only of the salt to twenty ounces of water at most.

EMBOSSING PRINTS.—T. DAVIES says: "When embossing prints in a cameo press, if they are on double albumenised paper, the albumen is often cracked, especially when it comes in direct contact with the die. This does not take place with the less glossy paper. Can you give me a remedy?"—We have no doubt that the trouble may be avoided by embossing the prints before they become "bone dry," that is, soon after they are mounted, and while the paper still retains some moisture.

GLASS FOR STUDIO.—S. WELLS writes: "I am told that some kinds of glass are very prone to turn yellow when exposed to the light for a time. Such glass would certainly be unsuitable for glazing a studio with. Can you tell me the best kind to use for the purpose?"—Some very white glass was in the market many years ago that, by long exposure to light, did change to a decidedly yellow colour, and we are not sure that it is made now. The ordinary sheet glass of commerce answers every purpose, and is very unlikely to change colour.

THE COMBINED BATH.—A. FRANKLIN says: "Kindly inform me whether the chloride papers are as permanent toned with the combined bath as the separate baths. I have sent you the formulæ which I use, and by which I get very good tones, but I have been questioned as to the permanency of them."—In reply: Our and many others' experience points to the fact that there is considerable risk, when using a combined bath, of imparting fugacity to the prints. We should recommend you to abandon the formula—containing alum and lead nitrate—for the combined bath you have been using, and employ separate baths, toning with gold and sulphocyanide, and fixing with plain hypo.

HAND CAMERA.—BEGINNER says: "I have just got a hand camera, but I cannot get a sharp picture with it. On showing the results to a photographer, he curtly told me that I had not properly focussed. That cannot be the cause, because the camera is a fixed-focus one, and requires no focussing. Can you explain the reason the pictures are not sharp?"—No, because there are so many reasons why they may not be. For example, the camera not held still during exposure, faulty lens, or worked with too large an opening, the lens not properly adjusted. If, however, the lens is properly adjusted for distant objects, it will not be in focus for near ones; therefore, if used for such, they will, of course, be out of focus.

DEFAULTING CANVASSER.—PHOTO say: "Will you kindly inform me what to do in the following case? About two years ago I appointed a man as agent for me in a distric. about seven or eight miles from Thornbury. He obtained some orders, which were executed and cash paid; but on the last two orders he has never paid over the money for same, which I know he has received. I did not know the names of the persons he had the orders from, so enclosed the bill of each with the photographs made out in blank. I have made several applications for the money, but have not been able to get it. I don't think it will be much use to put him in the County Court, as he is in debt to so many people in the town. What I particularly wish to know is, do you think he can be prosecuted for embezzlement?"—In reply: Probably a prosecution would lie, but you had better get legal opinion on the matter. The border-line between "embezzlement" and "matters of account" is not always plain.

TONING; LENS.—H. MASON says: "1. I should be obliged if you will kindly inform me, through your Answers to Correspondents column, what toning formula I should use to produce a fine grey tone? I have heard something about a 'salt bath,' but do not know the formula. Can I obtain a grey tone with any make or tint of paper? 2. Will you also kindly say if a No. 2B Dallmeyer lens is a cabinet or *carte* lens? I have one in use, but it will not cover a cabinet plate without the small stop No. 4. I am told it will cover 8×6 plate."—1. It is not stated what kind of paper is being employed, whether albumen, gelatine, collodio-chloride, or platinotype. It may, however, be mentioned that the more glossy the paper, as a rule, the more difficult it will be to get grey tones upon it. Plain salted, or some of the matt-surface gelatine papers, are best adapted for grey tones. 2. The "No. 2B" of the maker named is only intended for *carte-de-visite* size, though cabinet portraits are frequently taken with it when stopped down.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1893. Vol. XLIII.—AUGUST 14, 1896.

Contents.

EX CATHEDRÂ.

The Britannia Works Company have issued a special edition of *Photographic Scraps*, intended for professional photographers only. As far as the Company have been able, they have sent a copy to every professional photographer in the world. This issue of *Scraps* has been written by professionals for professionals, and such well-known men as Byrne (of Richmond), West (of Southsea), Wilson & Co. (Aberdeen), W. Crooke, W. E. Debenham, and Harold Baker contribute short articles descriptive of their experiences with the Ilford plates and papers. The Britannia Works Company are to be congratulated on their enterprise. We may add that, should any of our professional readers not have received a copy of this special issue of *Photographic Scraps*, a post card to the Company will bring one.

* * *

We tender our congratulations to our contemporary, the *Scientific American*, which has celebrated its half-century of existence by the publication of a special number, in which it gives a comprehensive review of the progress of American mechanical science since 1845. The number is full of deeply interesting reading. A short article is devoted to photography, and we observe from the reproductions given that Daguerreotypy was referred to in the very first number of our contemporary. The *Scientific American* has always looked with friendly eyes upon photographic progress, and we wish it a lengthened career in which to continue its encouragement.

* * *

Our *confrère*, Mr. F. Dundas Todd, editor of the *Chicago Photographic Beacon*, sends us the following interesting note with reference to the invention of the fish-glue process: "Hyslop, in conversation with me, frequently claimed to be the writer of the article in the *Artist Printer*, and, so far as I know, no one else has ever done so. The experiments, he said, on which he based the process were made for another purpose in the Camera Club, London, and the idea of using glue for half-tone work struck him in Chicago. I used to see Hyslop almost daily, but for two years I have lost track of him, so cannot refer him to Mr. Gamble's paper."

* * *

A correspondent writes: "May I point out an instance which may have escaped your notice, showing how an author should be careful, in writing stories in which the latest scientific discoveries are introduced, to fully inform himself on the subject. The *Strand Magazine* for July contains the first instalment of a new series of sketches, entitled 'The Adventures of a Man of Science,' in which the scientist, in utilising the New Photography to find out whether a Brahmin had swallowed a valuable diamond, informs us that, after having arranged his subject in such a position that the X rays should pass through his body, and turned off the light in the room, *he removed the cap from the camera*, and, after an exposure from seven to ten minutes, felt certain he had taken a careful photograph. It is curious to note that the same number contains an article fully describing how the New Photographs are taken."

* * *

Mr. Wallace Bennetto writes us, with reference to some remarks of ours, made a fortnight ago, touching his alleged discovery of photography in natural colours: "In some notes you give about my colour photographs you state you 'are surprised to learn from a correspondent that Mr. Bennetto declines to show the results to a photographer,' &c. Will you kindly state that no photographer has ever asked permission to see the pictures, that no one has ever asked on behalf of a photo-

grapher, and therefore the statement is false, and I will thank you to give me the name of your correspondent. I have shown the results to several persons as stated, and hope shortly to exhibit the pictures to the public, of which I will give you due notice." We give Mr. Bennetto's denial the utmost possible prominence. Our authority for the statement that he declined to show his results to a photographer was a Newquay professional photographer.

* * *

It will be seen, by reference to a paragraph which we print under the heading News and Notes, that Mr. Bennetto has declined the challenge of Mr. Bullmore to produce the results. These are to be exhibited shortly, and we hope to have the pleasure of seeing them. We would suggest the Royal Photographic Society's Exhibition next month as a suitable place for their display. We have no desire to say anything that might be construed as prejudicial or hostile to Mr. Bennetto, but, in this matter of the alleged discovery of photography in natural colours, the public has so often been misled by claims and announcements that have not stood the test of analysis, that each fresh "discoverer" has only himself to thank if his statements evoke feelings of scepticism when they are made in newspapers that are not qualified to pronounce an authoritative opinion on the specimens submitted to them.

ENGLISH PATENTS.

Comments have frequently been made in the technical press as to the way in which patents are granted in the United Kingdom. At the English Patent Office no inquiry whatever is made as to whether the invention is new, original, if it has been in use previously, or, indeed, if it has even been patented before. As a consequence, patentees often find themselves involved in costly litigation, which might well have been avoided if only a very limited inquiry had been made by the authorities before the patent was granted. In most other countries a patent is not granted without the authorities instituting an investigation, of some sort at least, as to the novelty or otherwise of the invention for which protection is sought.

In America, as well as in Germany, for example, the inquiry is very complete, and, if it is found that the invention is not new and original, the patent is refused. In the latter country the inquiry is more complete than in the former, and there it is not only necessary that the thing be new and original, but it must also be of public utility as well, or a patent will not be granted. This is a very good point in connexion with German patent law, inasmuch as it prevents a monopoly being created in trifling things which are not worthy of it. Owing to the strict investigation made by the German Patent Office before a patent is given, the validity of a similar patent, under the International patents arrangement, is seldom questioned in any other country. In England the Patent Office simply takes the money and asks no questions, and the same thing can be patented, over and over again, even if it were not original in the first instance. That is not as it should be, considering that the profits of our Patent Office are something like 100,000*l.* a year.

Here is a case in point, in connexion with photography, as to the way English applications are accepted. In our issue of the 24th ult. we printed the "complete specification" of a patent applied for by Mr. Davey for producing embossed portraits, and last week we gave the complete specification, with a brief append, of Mr. Taber for a precisely similar thing, embossed portraits. If the specifications be compared, it will be seen that the two methods are, practically, identical in every particular; yet, in the ordinary course, both patents will be sealed, and the patent will possibly have to be litigated afterwards, unless, indeed, one or other of the applicants is successful in opposing, before the comptroller, the sealing of the other's patent. That involves considerable trouble, and sometimes no little expense. Ten shillings has to be paid on giving notice of appeal, and twenty shillings by each party on hearing by the comptroller. It is rarely that the contending parties appear by themselves—they are usually represented by their patent agents or by counsel. This materially adds to the cost of the proceedings, and each litigant will have to bear his own costs, as none are allowed to the successful party.

It is a curious coincidence that the two applications just referred to were made within about a fortnight of each other, namely, Davey's on October 25, 1895, and Taber's on November 12, 1895; also that the two complete specifications were accepted within about the same time of one other, the former on June 20 of this year, and the latter on July 4 following. Both inventors, it is noteworthy, date from San Francisco, and the patents are applied for through English agents.

It cannot be too strongly impressed upon would-be patentees that the English Patent Office will grant a patent for an invention that may have no originality whatever in it, and which may even have been patented before, though, of course, such a patent would have no validity if contested in a court of law. This being the case, it behoves applicants who desire valid patents to make themselves, personally or through their agents, perfectly cognisant of what has been done previously before lodging their specifications. This, if done personally and completely, involves a great deal of time and trouble; and, if done by a patent agent, of course it incurs considerable expense. A very complete search by a patent agent is sometimes a costly matter, and in the end is not always conclusive in such subjects as photography.

Patent agents mostly confine their investigations to what has previously been done with regard to patents. Some, however, do, when a supposed valuable invention in connexion with such a thing as photography is in question, engage the services of an expert in photographic matters, and who is well versed in what has been done in the past. It is not necessary that a thing may have been patented before to make a subsequent patent for it invalid. It is quite sufficient if the thing has been shown publicly, worked, or published. Many patents now pass as being valid which would be quite upset on this score if contested. In some countries, we believe, prior publication or use does not invalidate a patent, provided the thing has not been published, used, or patented during the previous fifty years. Therefore an invention that may be over fifty years old, if it has been in abeyance the while, can there be patented as a new thing, and the patent will be valid. In England this is not the case, though some patent-law reformers would have it so.

The Action of Light on some Organic Acids in the Presence of Sunlight.—This is the title of a paper forming the thesis written by Henry Fay for his degree of Ph.D. in the John Hopkins University, and it contains a most valuable and interesting *résumé* of early investigations relative to the action of light on various bodies, many of which possess germs of value

appearing to be now quite lost sight of. It is almost impossible to make an efficient brief *précis* of the paper, which itself partakes of the character of an abstract, hence we merely call attention to its most interesting character, pointing out to those who have no means of access to the Proceedings of the University that the paper is being republished, *in extenso*, in the pages of the *Chemical News*, the first part appearing in the issue for July 31.

Action of Zinc on Sensitive Plates.—At a recent meeting of the Paris Academy of Sciences some singular experiments in this direction were described by M. R. Colson. Their outcome is to the effect that it is inadvisable to use cameras, slides, or plate boxes of metallic zinc, as M. Colson finds it to volatilise at ordinary temperatures in quantity sufficient to produce an effect on the plate. The action is energetic with freshly cleaned surfaces of the metal, as, for example, when it is abraded with emery paper, and falls off as the zinc becomes oxidised.

With reference to this remarkable fact and the volatilisation of metals at ordinary temperatures, a further reference was made at a succeeding meeting of the Academy by M. H. Pellat, who stated that, using steel in lieu of the zinc employed by M. Colson, he had obtained quite similar results.

The 1893 Eclipse.—A report at an apposite moment has been issued by M. Deslandres upon the work of the French eclipse expedition to Senegambia to observe the solar eclipse of 1893. As our readers have been made aware, some account of the work done has already been published, but the recent reports given describe the whole plan and purpose of the expedition, with particulars of the work accomplished. The programme involved photography of the corona and its spectrum, especially in the ultra-violet, and a spectroscopic study of the movements of the corona. M. Deslandres finds that, for photographs of the corona, rapid plates are not advisable. He has obtained his best results with plates of medium rapidity. When examining and collating the images on his various plates, this investigator found an annoying difficulty to arise: he was quite unable to determine on one of his negatives whether certain spots that appeared were the result of stellar images, or were mere particles of dust or imperfections of the film. Hence he makes the valuable suggestion that, when searching for intra-mercurial planets, two cameras, at least, should always be employed.

Acetylene.—There cannot be a doubt that this illuminant holds an important place in the scale of light-giving agents, and is the subject of grave consideration in high quarters. Granted a suitable burner, the light from acetylene is extremely powerful; the points that need consideration are the generators, mode of storage, relative safety as compared with ordinary coal gas. Already there are several generators described, or now placed on the market, some of which take the place of storage apparatus. For storing the gas, the most important plan is that of keeping it in the compressed form, and the statement was quoted at a recent meeting of the Philadelphia Fire Underwriters' Association that a cylinder four inches wide and four feet long would supply sufficient light for a ten-roomed house for three months. As regards safety, acetylene has to be looked at from several points, as its characteristics vary to a great extent from those of coal gas. At the meeting referred to it was stated that, if supplied to the consumer through underground pipes, in the same manner as ordinary gas comes to the consumer, it was just as safe as the latter; but, on the other hand, it must be remembered that it is liable to form dangerously explosive compounds with copper. It is further to be noted that Berthelot has shown it to be an endothermic compound, and so liable to explosions. Thus, if mixed with atmospheric air in the burner, it might strike back into the mains or the gasometer. We are not in a position to say whether this would be sufficient to initiate an explosion of the whole, but it has been experimentally shown that a reservoir of gas is capable of explosion by the aid of a percussion cartridge in the manner best adapted to explode a mass of gun-cotton.

The quality of the light is very restful to the eye in comparison with the electric and incandescent gas lights. In a recently published work dealing with this subject it is stated that a light rich in the violet and ultra-violet rays (such as is obtained with the arc and magnesium light) is hurtful to the eye, these, for example, being the rays in sunlight that bring on sunstroke or erythema.

Uses of Hydrofluoric Acid.—An important article, by Herr Carl F. Stahl, upon the commercial aspects of this chemical, recently given in the pages of the *Chemical News*, concludes by a brief account of various industrial aspects of the use of the commercial acid, and, as many of them would be available in the photographic laboratory, we give here an abstract of them: "The oldest, and, up to the present time, most extensive application is for etching on glass. For this purpose it can be applied in three different ways: in the gaseous form, by suspending the articles to be etched over a mixture of fluor spar and sulphuric acid. This is the oldest way of etching, and I believe most burettes, graduated cylinders, &c., for laboratory use, are still marked in this way. If applied in gaseous form, the acid leaves the surface opaque, while the liquid acid leaves the surface smooth and transparent. For the production of an opaque surface with liquid acid, many empirical formulæ are published, and every glass factory, or, rather, every etching boss, has his own secret formula. But they all aim to produce a mixture of hydrofluoric acid with a fluoride of ammonia, or potassium, or sodium, with which a number of other substances, such as sulphuric, acetic, or muriatic acids, or ammonium, or potassium sulphate, &c., are mixed: but it seems quite unnecessary." It may be noted that some years ago we gave a recipe for such a mixture or etching ink, in which sulphate of baryta was used, and we found it a very useful opaque etching material, the baryta giving it a body enabling it to be used with a quill pen, subserving, in fact, the same uses as the gum added to ordinary black writing ink. It appears that lead glass only requires an acid of half the strength desirable for a lime glass, and needs less time than to do the necessary work. It is further pointed out in the article that it is important that the article to be etched and the etching fluid should be at a temperature of about 15° C.

If any of our readers desire to make use of any of these formulæ, it is well to remind them that, if the strong acid is allowed to touch the skin, a dangerous wound may result. For example, a single drop falling on the hard hand of a workman, though its presence may at the time cause no feeling of pain, is yet capable of setting up a painful inflammatory action in half a day.

ON PRINT WASHING AND PRINT WASHERS.

The Washing.

This subject having recently been brought into prominence, and, to a certain extent, become a topic for general discussion, some account of an experience extending over a period of between thiry and forty years may be of some value. No one estimates Messrs. Haddon and Grundy's most valuable investigations in this matter more highly than I do; hence, though my own actual practice may not coincide with their recommendations, it is from no feeling of opposition on my part that I pen this account.

With regard to practical results, I may say that I have a series of register prints from the last portion of my various negatives bound in volumes, from No. I print, pasted in about twenty-five years ago, down to those of the present year. Of the first hundred pasted in the book, such of them as have, by close contact with the adjoining leaves, been protected from access of air, are as bright, and fresh, and free from fading as though placed in the volume to-day; and, with not one-half per cent. of exceptions, the same may be said of

the many thousands that have ever since been regularly placed into the register books, and are still being placed. I have, further, a few hundred prints, kept wrapped in brown paper and stored in a desk, which were taken prior to that time, and date from the very earliest days of alkaline gold toning. The same permanent character, *cæteris paribus*, appertains to them as to those in the books. Personally, therefore, as I appear to have nothing to gain by altering my method of procedure, I am in this position: I thoroughly endorse Messrs. Haddon and Grundy's recommendations, and I believe their system of short washing to answer every requirement, but, at the same time, I have no present intention of adopting it.

My prints receive, on an average, from fourteen to fifteen hours' soaking in running water. I am satisfied with their quality, and most assuredly no one can truthfully say that, in their case at any rate, long washing has the injurious effect that so many writers attribute to it. These remarks all refer to albumenised paper. With P.O.P. or collodio-chloride paper, short washing is a necessity if the best results are to be obtained.

There is one point to be well noted, as it is the key of the position with regard to all washing methods. When removed from the hypo, each individual print must receive, directly upon being removed from the hypo, a preliminary rinse in a separate vessel of water, before being placed in the ultimate washing receptacle. The theory underlying this procedure is simply that thiosulphate of soda, partly saturated with silver salt, in other words, the double thiosulphate of soda and silver, in presence of thiosulphate of soda, is less liable to decompose when in strong solution than when slightly diluted with water. Hence, with prints taken in mass from the fixing solution and placed into a dish of water, there is, though they be well stirred about, much probability of decomposition, when here and there among them some prints remain in contact with but slight admixture of water. It is most probable that, owing to the want of efficiency of washing methods generally, and the bringing about of these objectionable conditions, the complaint of fading through long washing has been promulgated.

It is a well-known and trite observation, though insufficiently understood even now, that the object of washing is less the elimination of hypo than the removal of the compound of silver and hypo from the fixed print. Let any one take a finished washed print, and, after soaking it in a weak solution of hypo, hang up to dry without a preliminary wash. It will, even after the lapse of a twelvemonth, be little the worse. Next, let half a dozen prints be taken from the hypo, placed in a small dish of water, and left there over night, without any stirring; the probabilities are that they will not be fit to look at the next morning. When the every-day conditions of washing are such as to render it possible that some of the prints may remain touching all the while, want of permanency is bound to follow. And herein lies the great virtue of short washing; the prints must be moved about, and individually separated, every chance being thus given for the fixing results to be soaked out. With long washing, it is too frequently the case that the printer expects length of time in the water to compensate for incomplete handling of the prints, especially in the first and second washing water. A case that came under my own personal observation may be here quoted to show what will suffice for some first-rate men. Many years ago I was invited to visit and advise upon certain matters a provincial photographer of the very first rank, one of the pioneers of the art and doing a large business. I was taken through the printing department at the close of the day, and the prints had just been placed to wash. The plan was simple, and as bad as simple. A large number of prints were placed in a twenty-four inch porcelain dish, slightly tilted; a water tap was placed over one corner, the water turned on, and allowed to run out of the opposite corner—the spout or lip! Upon my pointing out how inefficient such a system was, the proprietor blandly replied, "Oh, but the tap is running all night, and they get eighteen hours' washing." It is quite certain that in half an hour's time the prints would slowly collect in a compact mass towards the efflux end of the dish, and the fate of the prints would entirely hang upon the manner of their treatment when first placed in the water.

From the very earliest days of the alkaline gold toning, following the indications of Messrs. Davanne and Girard's classical investigations, the plan of a complete preliminary rinsing has been the leading idea of my practice, and should be of every one's; and to it almost wholly do I attribute the immunity from fading my prints have enjoyed when not subjected to other later disturbing influences. Such being the case, my further recountal of personal experience with washers may be robbed of some of its value or interest. Nevertheless, for those who care to peruse it, the following description is given of

The Washing Apparatus.

In the very earliest days when attention was given to washing under a proper system, the desirability of a frequent complete change of the water was pointed out, the method of turning the tap on to the prints, &c., and letting the water run away was shown to be imperfect. It is perhaps over thirty years ago when this was proved by calling attention to the length of time it would take under this system to get rid of the colour produced by putting a pint of ink in a bucket of water and turning the tap on. The ink representing hypo, it was seen that the latter would be equally slow in being removed. Hence, at a very early stage, "siphon washers" were devised. The prints were placed in a vessel from the lowest part of which proceeded a siphon, whose head was on a level with the surface of the water when at its maximum height. As soon as this was reached, the siphon was to begin to act, and, having a large bore, it would empty the vessel quickly (though water was coming in all the while) and then cease to act. The water thereupon began to fill the vessel again, and so on, automatically.

Practical men know that, as a matter of fact, this alternating action did not necessarily continue, for sometimes the siphon would continue dribbling off the water for quite a long time. Still, on the whole, the apparatus acted well, and it had a great repute. The first apparatus of the kind that I remember being offered for sale was made, I believe, by Bull, of Great Queen-street, and was a good one. The vessel was in effect a shallow bucket of zinc with straight sides; the siphon was placed inside, and had the longer limb passed through the bottom. The prints were prevented from being drawn into the siphon by means of a false bottom of perforated zinc. This pattern was made for many years, and until very lately was offered for sale, made of semi-porcelain ware. The objection to it was, that when the water emptied itself the prints would lie in the corners, and, forming a kink, never become detached during the whole of the washing, unless periodically attended to by hand. I determined to devise an improvement. After trying many experimental forms, I gradually evolved a shape that I adopted and kept in use till about a dozen years ago, till indeed cabinet pictures became the rule rather than the exception. These washing machines were for *carte* work, it will be understood. The ultimate form I designed was in principle the same, but, instead of a closed, cylinder-shaped vessel, I had one constructed of sheet zinc shaped like a deep saucer, three feet in diameter, with the siphon starting from the centre. One-third of it, the central portion, was a piece of perforated zinc carefully soldered so as to leave no surface roughness, and separated only by a fraction of an inch from the main body of the saucer. This was a perfect form. The great difficulty was to devise a mode of introducing the jet or jets of water that would keep the prints well separated. The prints would either congregate in a compact heap in the middle of the water, or be propelled to one part of the side of the vessel and obstinately stick there. I tried an immense number of forms, and finally hit upon what was practically a perfect method. Four upright and shaped lead pieces were soldered just above the saucer edge, and upon them rested a circle of lead piping, into which the water was led by an indiarubber tube. Out of this circle projected four short pieces of narrower lead piping through which the water issued into the dish, these small tubes being compressed at their ends to a narrow elongated aperture. The whole secret of successful practice lay in the way these four water jets were arranged. If they were bent so as to cause the water to issue from each in a jet parallel to the sides, a rotary motion was certainly imparted; but the prints did not change their position relative to each other. If, however, three of the jets issued in a direction parallel to the side, and the fourth jet came out in a line crossing them, pointing, indeed, very nearly to the centre, the rotary motion was not destroyed, but each time a print passed this jet it was

caused to gently slide over its neighbour, and all the prints in turn changed places.

So long as prints of small size, such for example as *cartes*, with a few cabinets only, were placed in the apparatus, its action was perfect; but, when cabinets came to be in more frequent demand, it was found that they were liable to become doubled up, and remain so through all the flushings and emptyings, with the result of a permanent disfiguring crease.

So serious did this evil become, and so apt were the prints to mass together, with, at the same time, the peculiar evils of the siphon system—the ceasing to refill as the level of the water became low—that it was felt necessary to entirely revise the plans for washing. I may incidentally remark that I also had large bowls of Doulton ware made on a similar system; but, apart from the great cost of the earthenware, I found the zinc the handiest to use, the coat of Japan varnish given to them, to prevent the action of zinc on dissolved silver, lasting a long time. The Doulton-ware bowls were made with perforations from the bottom to about half way up the sides, and with an outside projecting ledge whereon to fasten the funnel-shaped outer part which carried the siphon. All these, however, were thrown aside with the increase in cabinet portraits. The final plan adopted was a modification of the apparatus I had long before that time made for larger-sized prints, and is here described.

Square or Frame Washers.

As it would be quite impossible to have 12 × 10 and larger prints whirling about loose in a washer, I had made, about thirty-years ago, a washer, which to this day is quite efficient. The washer proper was a deep, square, wooden box on legs, with a siphon outside, the short leg being led inside the trough close to the bottom, and secured by a flanged end, puttied, and nailed into its place. The whole trough was coated several times over with shellac solution to keep it water-tight, and the joints of the sides and bottom were filled in with paper and white lead. The prints were placed in this on a series of trays, which were piled one on the other till only an inch or two of water rested above them. The construction of the trays was peculiar. It was a first necessity that they should be easily removable. To realise this, their framework was made of thick wire bent into a rectangular form, slightly smaller than the inside of the trough, with the object of rendering it easy to pass the fingers between a tray and the sides of the trough. To prevent these rectangles slipping over each other through not fitting closely to the box, each wire corner was made into a kind of loop, so that the tray fitted exactly in place. To prevent the trays actually touching each other, a short small foot was made by soldering a piece of bent wire at each angle of the frame. These were constructed for me by a manufacturer of galvanised wire netting, the whole frame being galvanised after being put together, thus making it compact and free from possible bare iron, which would lead to most undesirable iron rust. The framework made, it was readily converted into a tray by wrapping thin twine tightly round it, beginning at one end and finishing at the opposite. When the prints were ready to wash, after their first preliminary douche, they were placed one by one on the trays, which were then fitted in the trough, their own weight keeping them down, and the water gradually run in by means of an upright pipe running the whole height of the trough, and perforated with holes for the issue of minute jets of water. I preferred the use of twine before netting for the supporting medium, as it lent itself to causing the print to form a series of furrows, as it were, which allowed the water, when the trough emptied itself, to run off instead of lodging in hollows.

This trough, as I have said, lasted for many years. I had several of them of different sizes made, and eventually there was evolved from them a still larger one, constructed on similar lines, and yet more substantially built. This I use for both large work and *cartes* and cabinets. The mode of construction is the same, the details only are altered. Large troughs are difficult to keep water-tight if made of wood only, so that my later patterns are lead-lined, and the incoming water is all distributed over the surface by means of a copper tube, which runs round the top of the trough, and is perforated with minute apertures, so throwing the water like fine rain, and causing no current. The washings from the prints thus fall towards the lower part of the body of liquid by their own gravity. The water leaves the trough at the bottom by means of siphon, which is ingeniously devised to act as a mere overflow pipe or in the usual siphon fashion, at will, by opening or closing a small cock let into the bend of the siphon. I do not know whose invention this device is, but it was made for me by Messrs. Marion.

The trays for this trough are framed of wood instead of iron, and are somewhat like an Oxford frame in shape, to enable them to be handled and removed with ease. It is necessary to weigh them down when stacked and full of prints. Instead of using twine as the supporting medium—which I found apt to cause marks upon the prints, if they were left half dry upon them for any length of time—I ultimately hit upon gutta-percha cord. This is admirable in every way; it never marks the prints, there is no chance of its retaining any hypo and transferring to a print, and it can be readily cleansed. It is attached to the frame by means of small nails driven into the edge of the latter. The cord is secured to the first nail, passed across the frame, bent round the nail on the opposite side, then taken to the adjoining nail, across the frame once more, and so on till the whole is covered with a series of chemically inert, thin bars. On these frames are placed midgets, *cartes*, cabinets, twelve by tens, and so on, which rarely, if ever, become displaced during a whole night's washing, and which have every probability of being thoroughly washed, as no one print is ever in contact with another.

Finally, though I do think, if my advice were asked, I should say, Follow Messrs. Haddon and Grundy's plan of operations, I yet adhere to my old and tried plan of washing all night, feeling sure that, however careless a printer might be at work, he could not fail to put in the pictures in a way which would ensure their perfect washing quite automatically. G. Watmough Webster, F.C.S., F.R.P.S.

BY THE WAY.

Had I suspected, when I wrote last month the few lines about the nonsense that is talked on the subject of "amateurs and professionals," that I should have apparently hurt so many susceptibilities and brought down upon myself such a volume of abuse, I should have hesitated before writing, or perhaps altogether have refrained from penning the lines I did; but, having committed myself, there is nothing for it but to boldly "face the music."

Since those lines appeared in print, I have received a large number of indignant, and in some cases most abusive, letters from individuals who are without exception entirely unknown to me, and, I dare say, to the greater part of the rest of the world, apparently charging me with personally insulting them. As I cannot trace the name of any single one of my correspondents as having been in any way, publicly or privately, connected with any discussion on this seemingly very delicate subject, I am utterly at a loss to comprehend how I can be held to have had any hidden personal meaning in my brief remarks; but I *am* surprised at the number of strangers who find "the cap fits." The imaginary sting of my remarks appears to lie in the allusion to "a certain class of professional" and one individual concludes a more than ordinarily rude epistle by surmising that, in my "promised growl," I intend to "put the honest professional lower down than he is already, and praise up to the skies the wretched thing that calls itself an amateur." This is only one example of how the "honest professional" of a "certain class" jumps at false conclusions, but it seems to be the general idea running through my correspondence; I can only reply generally, that I am distinctly of opinion that, if these critics are fair samples of the noble creature that "calls itself" honest professional, I am distinctly of opinion that it would be far beyond my powers to place him lower than he has already placed himself.

The whole gist of the matter resolves itself into a misapprehension of facts, or at least of terms, and it was that circumstance that induced me to speak of the nonsense that is written with regard to the amateur question. The real amateur can in no sense be considered as interfering with the professional any more than my Lord's brougham can be looked upon as an infringement of the rights of the hackney cab; but, if my Lord authorises his coachman to fill

up his spare time by taking "fares," the somewhat touchy body that watches over the interests of "cabbies" would, provided he took out the necessary licence, have no legal cause for complaint, I imagine; and it just strikes me, to pursue the simile a little further, that in photography, as in other branches of industry, the cab trade being no exception, probably the public is better served by the "amateurs" who take up the business boldly than by many of the thorough "pro's." who rail so loudly on the subject.

But the quasi-amateur who takes up photography originally, perhaps for mere pleasure or because it is fashionable, and gradually drifts into selling his pictures whether at a profit or a loss, is no more an amateur than are the aristocratic cab-owners of the metropolis, but purely and simply a professional in a small way of business; and, so long as this is a free country and there is no licence required to use a camera or to sell photographs, there is nothing to prevent any one who possesses the necessary skill from doing just as he pleases in the matter of either making a profit out of his work or selling it at a dead loss to only partially recoup the expenses. But, when the shoe is found to pinch, it is not the right thing to make it a question of amateur *versus* professional, for it is simply a matter of trade prices: and if the so-called amateur can do better work, get more customers or work for less money, so much the worse for the professional, who can't or won't. He feels it hard, no doubt, and it is calculated to make him sore, to find his business falling off, and prices going steadily down, but don't let him lay the blame on innocent shoulders —those of the amateur.

The same sort of thing has been going on since the earliest days of photography, and no one, not even the highest in the profession, can dream of getting the same prices as in the "golden days" of the Daguerreotype. Except in very few instances, it has always been the energetic and enterprising artist, who was willing to do really good work at a moderate price, who has done the biggest business; and it has ever been the "slow coach," or the incompetent, who has shouted loudest against "cutting" prices. I well remember the outcry there was many years ago when a leading firm of fashionable photographers brought their prices down to seven-and-sixpence per dozen for *cartes-de-visite*; but it was not the leaders of the profession that complained most loudly or at all, but those whose inferior work put them out of competition. Quality will always command its value, and in photography, as in every other business, it is a case of the survival of the fittest, and it is the weaker and inferior that go to the wall first and make the loudest outcry.

That is just about what I meant when I wrote of the nonsense that is talked on the amateur question, which is really no amateur question at all; I had no intention to either belittle the professional or bepraise the amateur. Each in his way stands alone and beyond personal comparison. The only possible comparative test is that of quality of work; but, whether that be good or bad, the true amateur can never in any way interfere with, or injure, the professional, who, in turn, if of the "right sort," will never find any cause to fear a competition that does not exist. In the words of the presidential address at Leeds, "Let us all be known as photographers," and, if any distinction be necessary between different classes of *traders*, let it be "profession" and "shamateur" (to use the happy definition suggested some years ago), but leave the *amateur* out of the quarrelling.

I had no intention of discussing the *pros* and *cons*. of an already well-ventilated subject, or of suggesting any remedy for the present state of affairs, for such I deem to be an impossibility. But there is one phase of the question that is harped upon by nearly all my critics, as well as by almost every writer on the professional side of the subject, for years past, to which I cannot help alluding. I refer to the allegation that amateurs are supplied by the dealers with their materials on as good, if not on better, terms than the professional; and, as was said only a short time ago that, thanks to our advertising annuals, every one now knows exactly the price of everything, and consequently will not pay reasonable prices.

Now, so far as the first part of the statement is concerned, I for one can see no reason why a professional photographer should be charged any less for an ounce of pyro, say, than an amateur. It is a custom, I know, in the druggist's trade to have a sliding scale of terms, and "doctors' prices" are materially lower than those charged to the general public. But this is only a private arrangement between the chemist and the medical man, in order to secure a good and regular customer. Similarly, no doubt, if any professional photographer would give his undivided trade to any one dealer, "special terms" might probably be arranged if it were worth the dealer's while; but, sad to say, in these days of competition, I am afraid the professional likes to buy in the very cheapest market just as well as the amateur, and would not long adhere to any such arrangement if he saw a chance of doing better. He, at any rate, has the advantage of being able to buy in quantity, and so secure an extra discount; but, if he be one of the class who used to go down to "the Cut," on Sunday morning, for two ounces of collodion, he must not expect the special terms usual with "shipping orders."

It has been also said, I think, lately, that the dealers nowadays study the amateurs in preference to the professionals. Well, I should think the dealers very much wanting in common sense if they did not give so little attention to the "predominant partner." The professional has mainly the amateur to thank for the low prices at which he can himself get his goods now, as compared with a few years ago. What but the immense increase in the number of amateurs has brought down the price of pyro, within very few years, from four-and-sixpence to a shilling an ounce? In the ante-gelatine days the relative proportions of the professional and amateur element were so different from what they are now, that the larger quantities of material consumed by the former made him the better customer, and so worthy of special consideration; but, nowadays the amateurs so vastly outnumber the professionals, and, as it has been facetiously if cruelly said, "spoil so many more plates," that they cannot now be relegated to the "back seat" they formerly filled.

With regard to the production of trade enlargements, another point that has been raised, there certainly would seem to be ground for complaint against the enlarging firms if, as alleged, they supply enlargements to amateurs on the same terms as professionals; but, so far as I am aware, the "trade terms" issued by such firms are subject to the production of business card if the customer be unknown, and I imagine that those who cater for the trade only would be careful to observe the rule. But even here a complication arises from the competition of the "stores," who will supply single enlargements to their customers at precisely the published trade prices. If, then, the enlarging firms adhere strictly to their trade rules, the professional photographer is very little better off. As regards the "shamateur" it is a matter between him and the enlarger, who must elect to class him either as an amateur or a trader as he chooses. If he wants the enlargements "to sell again," he is clearly entitled to some discount or allowance from the prices usually charged, and, as published prices are at everybody's finger ends, he cannot get much out of the transaction except at trade prices.

And that brings me to one point or argument in which the professional impeaches himself, namely, the statement that the public is so well educated in the matter of trade terms that they will not pay *reasonable* prices. I have known, as an absolute fact, an enlargement, which, made and framed complete by a firm of trade enlargers at a cost of seventeen or eighteen shillings, with perhaps a shilling or two extra for carriage, &c., was charged to the customer three guineas and a half. This may be an extreme case, but, if it be anywhere near the ordinary professional's conscientious idea of *reasonable* terms, I don't wonder at the lay public refusing to pay them.

To sum up: I hold no brief for either professional or quasi-amateur. The real amateur is out of the question altogether, but I want to show where the difficulties lie between the two. Until there is some sort of tax or licence levied, or until the photographic tariff is placed under a compulsory trade union, the same sort of difficulties must continue; but, while they exist, it is absurd and ridiculous in the extreme to blame the amateur. Our societies might commence to do something in the way of having a sharper line drawn between amateur and professional, but *I* scarcely like to suggest in what direction.

DOGBERRY.

FOREIGN NEWS AND NOTES.

Yellow Screens.—An important paper, by Dr. Otto Buss, appears in the current number of the *Photographische Correspondenz* upon the action of various yellow dyes upon the spectrum, particularly with regard to the ultra-violet. Pieric acid, safranine, Martin's yellow, naphthol yellow S., aurantia, fast yellow, metanil yellow, and auramine all show more or less absorption of the visible blue and violet end of the spectrum, but yet allow considerable quantities of the ultra-violet to pass, and in most cases the distinctly marked bands of non-absorption lie beyond λ 360. Several vegetable colouring matters were also examined, such as saffron, turmeric, mace, euonymus petals, and also some of the pure crystalline colouring matters, such as xanthophyll, xanthacarotine, and of these the xanthophyll completely absorbed the ultra-violet, and, if it were possible, this would make a good isochromatic screen. Alcoholic extract of the yellow petals of corydalis lutra, primula elatior, calendula, and carthamus, and the yellow colouring matter of the lemon absorb also the whole of the ultra-violet.

Dr. Buss points out that most of the existing formulæ for yellow screens are extremely unsatisfactory, and that they, like the commercial glass screens, only absorb the rays from H in the violet to G or F, and, because our eyes are extremely insensitive to these rays, a slight damping of these rays is falsely recognised as total absorption, whilst actinic rays may still pass; and the only way to really test a screen is by photographic examination of a dye in quartz spectroscope, which permits the whole of the ultra-violet to pass.

Some Well-known Formulæ.—As an example of how some of the screens act, he takes Vogel's formula for making yellow screens, which is a solution of aurantia in collodion 1:250; 20 c.c. of this being allowed for a screen 13×20 c.c., the thickness of the resulting collodion film would be $\frac{20}{13\times20} = 0.0077$ mm. Buss points out that he used a solution 1·5000 in a thickness of 5 mm., which was thirty-two times stronger than Vogel's, and yet this allowed ultra-violet light from λ 370 to λ 300 to pass, and he sarcastically asks, "How much more, then, would the thirty-two times thinner film allow to pass?"

The Absorption by Glass.—It might be assumed that the glass itself of the screen or the lens would absorb the ultra-violet, but Eder and Valenta have pointed out that 1 c. of the most ultra-violet-opaque glass only absorbed up to λ 340, and, as the glass used for screens is very much thinner, this cannot be taken into account. Further than this, it is pointed out that even the thick lenses of the present day are really very transparent to the ultra-violet, and therefore could not make up for the weakness of the screens.

Dark-room Windows.—The use of aurantia, picric acid, auramine, &c., for making dark-room window screens, ought therefore to be avoided, and it is quite possible that the use of these absorbents may account for many fogged plates. Every material used for blocking out light from the dark room ought to be tested in a quartz spectroscope to see whether it allows any ultra-violet to pass or not.

The Ultra-violet in Practical Work.—The action of a yellow screen is to cut down the blue and violet so that the maximum action of light may be in the yellow and yellowish green. Our eyes are quite insensitive to the ultra-violet, and cannot discern whether a particular light contains ultra-violet rays or not, and Dr. Buss states it is quite immaterial whether ultra-violet rays play any part in an ordinary orthochromatic exposure or not, as long as they do not increase the action of the blue and violet rays. If we use, therefore, any substance as a yellow screen which absorbs the blue and violet, but which allows the ultra-violet to pass, we permit the latter to intensify the yellow and green, and thus photograph the yellow and green by yellow, green, and ultra-violet rays. A yellow screen, which transmits the ultra-violet will enable us to obtain a stronger action in the yellow and green than one which absorbs the ultra-violet.

Alizarine Blue Bisulphite.—Dr. Eberhard, of Gotha, continuing his researches upon orthochromatic plates, suggests bathing a Cadett lantern plate (black tones) in the following sensitiser:—

Water	100 c. c.
Alizarine blue (1 : 500)	100 „
Rose des Alpes (1 : 200)	2 „
Ammonia (sp. gr. 0 : 91)	1 „
Silver nitrate (1 : 40)	46 drops.

The solutions are mixed in the above order, well shaken and filtered, and the plates bathed for two or three minutes. The red sensitiveness of these plates is very high, and the strong sensitising action of the Rose des Alpes (Thiodichlortetraiodo fluorescence made by Durand, Huguenin, & Co., of Hüningen, Elsass) appears from $C\frac{1}{2}$ D to E, so that a very nearly closed band from the extreme red to the ultra-violet is obtained.

Two well-known Men.—M. Adolphe Martin, and M. J. H. Voight have gone over to the big majority. M. Martin calculated out and constructed most of the instruments in the Paris Observatory, and his name will probably be familiar to many as a maker of photographic lenses, and as the author of a very good method of silvering glass. M. Voight was, for many years, the President of the Frankfort Photographic Society, and a constant contributor to foreign journals.

Action of Light on Uranyl Oxalate.—Mr. Henry Fay, contributes a long paper on the action of light on various uranyl salts, and amongt them uranyl oxalate, which is very rapidly reduced to uranous oxalate, the sensitiveness being much greater than ferric oxalate. It is curious to note that very little use is made of the light sensitiveness of uranium salts, although it was suggested in 1889 by Alleyne Reynolds to use uranyl chloride in combination with sodium ferric-oxalate, and chloro-platinite of potassium, when the uranyl would be reduced to uranous chloride, which in contact with the ferric salt would reduce the latter to ferrous, and itself be converted to uranyl chloride again, the resulting image being very soft and free from solarisation.

"Niederschlags Membran."—By this pretty title, which may be translated by "membranous precipitate," Liesegang designates a peculiar surface precipitate, which forms when a chlorised film of gelatine is immersed in a weak solution of silver nitrate, and prevents the penetration of the silver solution into the film. He argues from this that, when using the cupric bromide intensifier, a strong solution of silver nitrate should be used for blackening, and that gelatino-chloride prints should be well washed before toning in a sulphocyanide bath, or a surface precipitate of silver sulphocyanide may be formed, which may cause unequal toning by preventing the access of the solution to the deeper-lying particles of the image.

Stereoscopic Radiographs. — According to Professor Schiffner, it is possible, from stereoscopic radiographs, to tell not only the exact position of an opaque object as well as the distance from the top or bottom of the box in which it may be. The object has merely to be taken or radiographed from two points, and, if the object is lying on the bottom of the box, it will appear in the same position on each plate; whereas, if it is not on the bottom, it will appear in different positions, and from the difference in the two positions and the distance of the tube can its position be calculated.

THE PHOTOGRAPHIC COPYRIGHT UNION: ITS POSITION AND PROSPECTS.

The praiseworthy attempt to bring the Photographic Copyright Union once more prominently to the notice of professional photographers through the medium of the Leeds Convention was defeated by circumstances, the time and the occasion, the Wednesday forenoon, just

anterior to the taking of the all-important group, not being the most favourable for the purpose. Our own interest in the progress of the Union, however, together with the strong claims to the support of professional photographers which that body undoubtedly possesses, has since induced us to take advantage of an opportunity of inquiring for ourselves into the present position of the Union, and of obtaining such other information concerning its progress and prospects as would be likely to prove instructive to members and non-members alike. The correspondence that reaches us week by week proves that a great deal of ignorance and misconception prevails with regard to the Union, which, it is very desirable, should be removed. We are indebted to Mr. Frank Bishop (the President of the Union), and to Mr. J. J. Elliott (the Vice-President and Founder of the Union), for kindly answering our inquiries, and thus enabling us to set forth the following details.

The Work of the Union.

Naturally, the first question that occurs to us has reference to the present position of the Union; and we obtain the satisfactory reply that it has a membership of several hundreds, a considerable and increasing reserve fund, and that the Union's influence in the protection of photographers' copyright is greatly extending. Nevertheless, it is felt that there is scope for a membership of, at least, 2000 or 3000, and that it is only the ignorance of photographers as to the aims and objects of the Union that impedes its progress. The Union acts as a species of advising Society for them in copyright matters, the extensive experience of the Committee and of the Solicitors (who are expert in copyright law) being utilised for this purpose. Moreover, the Union registers members' photographs, and supplies the forms (which we reproduced in the Journal of January 10 last), giving authorisation for the reproduction of photographs to newspapers The usual method for the transaction of business is by addressing the Secretary, Mr. H. Gower, Photographic Section of the London Chamber of Commerce, Botolph House, Eastcheap, who answers inquiries. In important or complicated cases the Committee are consulted, and in cases where redress is to be had by legal means the Solicitors act. From the commonplace book of the Committee (which meets monthly) we learned that quite recently advice had been sought by photographers in India, Africa, Ireland, Scotland, London, and the country, the majority coming from the country and abroad. It may be said that the main work of the Union consists in obtaining redress for the piracy of, and compensation for the use of, copyright photographs, but we were informed that it unfortunately often happens that members, instead of putting the matter at once into the hands of the Copyright Union, enter into direct communication with the offending paper, thus jeopardising their own interests.

The Executive of the Union has, so far, every reason to be satisfied with what it has accomplished, but is justly entitled to look for a far larger membership.

The Obstacles to Progress.

The obvious question as to why, with a total of between 4000 and 5000 professional photographers in the United Kingdom, the Union does not number its members by thousands instead of hundreds, elicits the statement that photographers generally do not know that there is no fee for membership. It cannot be too widely known that there is *no* subscription. The expenses of the Union are met by voluntary donations and a percentage on the amounts recovered, and it is intended that this plan shall be continued to be adopted for paying expenses, and it deserves to be urged, with all possible emphasis, that, by joining, members incur no financial liability whatever, either immediate or prospective. The only liability is in the obligation not to allow their copyright photographs to be reproduced for less than the minimum fee of 10*s*. 6*d*.

Again it seems that there is an impression that the obligation of being obliged to charge a minimum fee may react adversely to photographers' interests. Against this misconception we were cited numbers of cases in which members experiences were all to the contrary; indeed the effect of the minimum is being felt in the readiness with which a large section of the illustrated press now, as a matter of course, and without solicitation, tender fees. The Committee have every cause to be gratified for not having swerved from the minimum charge of 10*s*. 6*d*., and they regard strict adherence thereto as the crucial point in the administration of the Union.

Furthermore, some photographers imagine that the Union works only for a few London photographers; as a matter of fact, we were assured, and are personally satisfied, that such is not the case—that provincial photographers receive a larger share of attention than their town brethren, who are probably better able to take care of themselves in copyright matters. But we regard the feeling that the Photographic Copyright Union exists solely for the benefit of a few photographers as unworthy of further notice; though it certainly must be regarded as an obstacle to its progress. There is also, we learn, a feeling with many photographers that they are in no danger of having their works copied or pirated, and that therefore the Union is of no service to them. Independently of the fact that our own recent experience of such matters accentuates the fallacy of such an attitude, Mr. Bishop and Mr. Elliott produced almost overwhelming testimony to the contrary. "The photographer never knows when he may want the services of the Union," we were told, and therein to our mind lies the best argument adducible in favour of every photographer joining it.

Some Minor Points.

Many photographers are still content to give the use of their photographs in return for the "privilege" of having their names printed under the reproduction; but this "advertisement" has, we were told, been shown to be practically valueless. The Union takes up the businesslike position that, whatever is worth having is worth paying for. As to what constitutes a copyright photograph much misconception exists. A photograph is copyright so soon as it is produced, but registration at Stationers' Hall is necessary to, as it were, make the copyright a legal integer. The photographer may register whenever he pleases, though he cannot avail himself of any statutory remedies until the photograph *is* registered; but, if a copyright picture is pirated *before* registration, he can subsequently register, when he is entitled to avail himself of all the statutory remedies against the reproducer for all copies sold *after* registration.

The administration of the Union itself is one in which all members may exercise a share or influence. It is governed according to rules; an annual meeting of the members is held, and the Committee and officers are elected by the members. We state this much in further refutation, if such were necessary, of the statement that the Photographic Copyright Union is run in the interests of a minority. It appeals to *all* photographers, and its administration is conducted on a broad and popular basis.

Apathy and ignorance have been obstacles not inferior in extent to the opposition of the illustrated press that the Union has so far had to fight; but it is pleasant to know that the press and the Union are working together in a feeling of harmony which is daily on the increase. The hard work of the past three years is bearing fruit, and it may be not unfairly claimed that the Union has, besides being of pecuniary service to many of its members, caused professional photography to be regarded with increased respect, and thus materially helped to raise its status.

The Future of the Union.

The future of the Union is in the hands of the professional photographers of the United Kingdom. To us it appears that it has earned the undying gratitude of the profession by giving to a copyright photograph, what it distinctly did not possess before, a market value. The efforts of the Union to compel users of copyright photographs to pay for them are perceptibly having a wide-spread effect, for payment is now made as a matter of course where once it was quite exceptional, if done at all. In return for these efforts, the Union asks for the moral support of all photographers, which can be best and most effectively given by taking up membership, and adhesion to the agreement not to charge less than the minimum fee of 10*s*. 6*d*. for the reproduction of their copyright photographs.

We conclude by recommending the Photographic Copyright Union to the hearty support of all our readers, who, or such as are not members, may obtain full particulars of membership from the Secretary, Mr. H. Gower, Photographic Copyright Union, London Chamber of Commerce, Botolph House, Eastcheap, E.C.

FIFTY YEARS OF PHOTOGRAPHY.

[Scientific American.]

In the entire range of invention and discovery nothing shows a more brilliant series of successes than the art of photography.

A hundred and fifty years ago, copies of writing had been made by the action of light on sensitive paper. Giambattista Porta had invented the camera obscura; and more recently Niépce and Daguerre, by different methods, had succeeded in making sun pictures; and Fox Talbot had invented the calotype or Talbotype; Herschel had given to the impression made from the object the name "negative," and to the print from the negative the name "positive."

Fifty years ago, in 1846, Schonbein discovered gun-cotton, and soon after collodion was produced by making a solution of gun-cotton in alcohol and ether. It was almost immediately adopted by Archer for a film in lieu of albumen and gelatine. Pictures produced on the sensitive film having collodion as the basis superseded the calotype and Daguerreotype, and were made almost exclusively after this discovery up to within fifteen or sixteen years. This film is still used by many photographers for special purposes, but more particularly in photo-engraving, and for transparencies and lantern slides. The collodion film was used for making negatives as well as positives; some of the best photographic pictures ever produced were made by means of wet-plate collodion-film negatives, albumenised paper being used in making the positive prints. Prior to the use of albumenised paper sensitised with the silver salts, glass positives, called ambrotypes, were introduced by making a very thin negative image and backing the plate with asphaltum varnish or black velvet, the black background producing a positive effect. In some cases they were bleached by means of a solution of mercuric chloride. Collodion positives are still made upon thin japanned iron, commonly called tintypes.

After a great many experiments, the modern dry plate was produced, not in its present state of perfection, but in a way which indicated its capabilities. The gelatine dry plate could not be made in perfection until after the gelatine itself had been improved so as to render it suitable for this purpose. It is to the perfection of the extremely sensitive dry plate that the great popularity of photography is to be attributed. Barring the bicycle, probably no craze was ever so widespread as that of modern photography. Methods of manipulation and improvements in lenses and apparatus have kept pace with improvements in the art itself, and the large demand for apparatus and material effected a corresponding reduction in prices. Lenses have been devised for every use, and the very recent improvements in optical glass have rendered it possible to produce lenses which are marvels of perfection.

It is needless to mention the improvement in cameras and portable apparatus, for we think it would be almost a rarity to find a family of which some member is not practically interested in photography. A great impetus was given to modern photography by the invention of the hand camera and more particularly that of the magazine hand camera. Magazine cameras in great variety have been brought out. Most of them have been fitted for the use of roll films or cut films, but a small proportion are arranged for receiving glass plates. Such cameras have been made as large as 8 × 10. The beautiful modern folding camera, being very light and portable, has become a great favourite with both professionals and amateurs. It is even more portable than the magazine camera.

From the ordinary side window as a source of illumination, the Daguerreotypist turned to the skylight, and special skylights, some of them of large size, were constructed and used to great advantage in the production of pictures which have never been surpassed in soft, delicate shading.

After the invention of highly sensitive plates it was possible to make a good picture with a smaller skylight, also with a good side light, when suitable screens were provided. With sensitive plates came the use of artificial lighting and flashlights for instantaneous work in the night, and in caves and dark places.

Since the development of the electric light many photographic establishments have been fitted out with electric-lighting apparatus, permitting of taking portraits at night and in cloudy weather. An additional advantage in the use of artificial light is that of carrying on the work on the first floor, thus saving stair-climbing or travelling in the elevator. With proper management the amateur photographer may procure flash-light pictures at home in the evening which compare favourably with daylight work.

Early in the history of photography it was noticed that true colour values were not rendered in any photographic pictures. Yellow, red, and green always appeared darker in the picture than in the object, while blue and violet appeared lighter. To correct this defect in photographic pictures, the plates were made colour-sensitive by colouring them with applied dyes, or by incorporating the dyes with the emulsion used in coating the plate. The difference between pictures taken with orthochromatic plates and those taken on ordinary plates is very noticeable. Coloured screens have been used in connexion with ordinary rapid plates for securing similar results, and in copying paintings, tapestries, and other works of art depending upon colour value for effect. Both the yellow screen and the orthochromatic plates have been applied simultaneously.

Very early in the history of photography, in fact before Daguerre's discovery, the workers in this line conceived the idea of making pictures in the colours of nature, or as they are shown on the ground glass or screen of the camera obscura. Fugitive coloured pictures were made, which could be examined by weak light, but they were quickly destroyed when exposed to strong light. No means were ever found for fixing these coloured images. Experiments looking forward to the discovery of some means of fixing and preserving the images have been carried on without much success since the days of Daguerre.

Tricolour photography is not a strictly modern invention, but it has been perfected to a great extent within ten years, and very pleasing pictures can be produced by this process, although they do not present the ideal coloured picture. Such pictures are produced by using three separate plates, and taking the pictures through three separate colour screens—red, green, and blue. A positive made from a negative taken through a red screen is transparent through all places where pure red is seen in the subject represented, also more or less in parts representing purple or violet and orange. A positive taken through the green screen will be transparent in the parts that are green in the subject. It will be transparent also in the parts representing yellow. In a similar way a picture taken through a blue screen is transparent to the parts representing the blue portions of the subject.

According to one method, the prints from the negative are made upon sensitised gelatine, the gelatine carrying the colour which is required to build up the portion of the picture demanding that colour, When these three prints are made and superposed, they reproduce approximately the colours of the scenes represented.

A modification of this method, which results in truer colours, is accomplished by making three positive black-and-white prints representing the three colours, and projecting them on a screen, where they are superposed, suitable coloured screens being placed in front of each positive. Some very beautiful effects are produced by this method.

Lippmann, of Paris, not long since discovered a very simple and interesting method of producing photographs in colour. He first produces a suitable negative, prints a positive from the negative, and backs up the positive with a film of mercury. The image is seen by reflected light, and the colours are produced by interference of light in a manner similar to Newton's rings. [This description of Lippmann's process is not *quite* accurate.—Eds. B. J. P.]

Among other developments in photography within very recent years may be mentioned several methods of reproducing photographic pictures in black-and-white, and other tints by lithography, photogravure, collotype, half-tone, and line etching. The collotype is a simple style of photographic reproduction. In making the collotype, the glass which is to support the film is finely ground, and a solution of albumen and silicate of soda and water poured over it to form a foundation for the film. Upon this foundation is poured a solution of ammonium bichromate and gelatine in water. When the plate is dry it is exposed to the light through a negative and immersed for a time in cool water, after which it is dried in a bath of glycerine and water, and coated with printing ink. The plate is then printed according to the method of the lithographic printer.

In photogravure the shadows are depressed in the plate, and the printing is done on practically the same principle as that of steel or copper-plate printing.

In making a photogravure, a transparency or positive is taken from a negative by any of the well-known methods, and a copper plate larger than the print to be made is cleaned and dried, and then coated with a solution of gelatine and potassium bichromate in water. The plate is then dried, placed in a printing frame, and exposed through the transparency or positive, after which the surface of the film is dusted, etched, and cleaned, when the plate is printed from, after inking and wiping off, either in the same manner as a copper or steel-plate engraving, or as an etching, leaving a thin film of colour in different positions on the high lights to modify the effects.

In the half-tone process the sensitive plate is exposed in the camera through a grating, which leaves a texture on the negative, which, when printed through on the bichromatised metallic plate, produces lines or dots, which are etched, and which, in printing, leave high lights and carry the ink, which produces the shadows. When three plates are made through three coloured screens, and three impressions are produced from the plate with appropriate colours, very good pictures approximating the tints of nature are produced. This is now the most popular method of illustrating with colours. Recently, improvements in the shape of apertures in the screen have been made.

With the improvements in photography, the projection lantern has been rendered very efficient, so that either coloured or black-and-white pictures may now be projected upon a screen twenty-five feet square, producing very satisfactory results. In fact, some of the most popular entertainments of the day are on this order. With improvements in lenses, plates, and developers, the speed of photography has been increased to such an extent as to produce a distinct image in the space of $\frac{1}{1000}$ of a second. This renders it possible to catch images of insects, birds, and other animals, and even projectiles, in their successive positions. By reversing the process these images are reproduced in such rapid succession as to give the pictures all of the movements of life, without any apparent break in continuity. This is, in brief, the principle of the kinetoscope.

Photography has proved itself to be of incalculable value to other sciences. In surgery it has been employed for differentiating tissues. It has been employed for detecting stains invisible to the eye. It is a faithful recorder of physical phenomena, and has been made by Röntgen, in connexion with the X rays, to show interior portions of the body, and make other disclosures of a startling nature.

In addition to these, photography has been used for grasping celestial objects beyond the power of the eye and telescope, for mapping the heavens, measuring and recording spectra, showing the structure of the sun, revealing the extent of nebulæ, picturing comets, and making records of eclipses and other phenomena. It has also revealed things beyond the power of vision and the microscope.

McDONOUGH'S IMPROVEMENTS IN AND RELATING TO COLOUR PHOTOGRAPHY.

The nature of Mr. McDonough's improvements may possibly be gathered from his claims, which are as follows:—

1. A frame for holding or printing photographic pictures in colours, consisting of a receptacle for holding a negative or positive plate, a cover for holding a printing paper or material in contact with the plate, and means for moving the plate, or paper, or material, relatively to each other, to cause lines or patterns on their faces to register with each other.

2. A frame for holding or printing photographic pictures in colours, consisting of a receptacle for holding a negative or positive plate, a cover for holding a printing paper or material in contact with the plate provided with a surface of rough or tacking material next to and in contact with the paper or material, to prevent the same from shifting or expanding while printing, and means for moving the plate, or paper, or material, relatively to each other, to cause lines or patterns on their faces to register with each other.

3. A frame for holding or printing photographic pictures in colours, consisting of a receptacle for holding a negative or positive plate, a cover for holding a printing paper or material in contact with the plate, and springs and screws operating in opposition to each other for moving the plate, or paper, or material, relatively to each other, to cause lines or patterns on their faces to register with each other.

4. A frame for holding or printing photographic pictures in colours, consisting of a receptacle for holding a negative or positive plate and printing paper or material in contact, and provided with adjusting screws to effect the registration of the lines on the plate and paper.

5. A screen or plate for photographic purposes provided with coloured substances arranged according to regular recurring patterns—as dots, lines, figures—and having a portion where there is a fixed or invariable and distinctive characteristic which is reproduced in the sensitive material applied to it, by which such material may thereafter be registered or adjusted in position in use.

6. A screen or plate for photographic purposes provided with coloured substances arranged according to regular recurring patterns—as dots, lines, figures—and having a portion or portions where one line or pattern is opaqued printed over.

7. A screen or plate for photographic purposes provided with coloured substances arranged according to regular recurring patterns—as dots, lines, figures—and having a portion where a line or pattern of one colour is opaqued and others of other colour or transparent and clear.

8. A screen or plate for photographic purposes provided with coloured substances arranged according to regular recurring patterns—as dots, lines, figures—and having a portion where a line or pattern is transparent and clear, and others of other colour opaqued.

9. A screen or plate for photographic purposes provided with coloured substances arranged according to regular recurring patterns—as dots, lines, figures—and having a portion or portions where all lines are transparent and colourless.

10. A screen or plate for photographic purposes provided with coloured substances arranged according to regular recurring patterns—as dots, lines, figures—and having a portion or portions where all lines are spotted or opaqued.

11. A screen or plate for photographic purposes provided with coloured substances arranged according to regular recurring patterns—as dots, lines, figures—and having a portion or portions where one line or pattern is extended beyond the others.

12. A screen or plate for photographic purposes provided with coloured substances arranged according to regular recurring patterns—as dots, lines, figures—in combination with a screen for registering purposes, having transparent and opaque lines or patterns corresponding in register, size, and alteration with the lines or patterns of the multi coloured screen.

13. A negative or positive photographic plate made with recurring patterns—as dots, lines, figures—and having a portion where there is a fixed, and invariable, and distinctive characteristic, which is produced in the sensitive material of the plate, and by which the plate may thereafter be registered or adjusted in position in use.

14. A negative or positive photographic plate made with recurring patterns—as dots, lines, figures—produced by the action of different coloured light in regular alternating order, having a portion of its surface printed and developed for the purpose of registering by means of and with a transparent line or pattern in each series of lines or patterns.

15. A negative or positive photographic plate made with recurring patterns—as dots, lines, figures—produced by the action of different coloured light in regular alternating order, having a portion of its surface printed and developed for the purpose of registering by means of and with an opaque line or pattern in each series of lines or patterns.

16. A negative or positive photographic plate made with recurring patterns—as dots, lines, figures—produced by the action of different coloured light in regular alternating order, having a portion of its surface printed and developed for the purpose of registering by means of and with an opaque spot covering all lines and patterns in that spot.

17. A negative or positive photographic plate made with recurring patterns—as dots, lines, figures—produced by the action of different coloured light in regular alternating order, having a portion of its surface printed and developed for the purpose of registering by means of and with a transparent spot covering all patterns in that spot.

IRVING'S IMPROVEMENTS IN OR RELATING TO PHOTOGRAPHIC CAMERAS.

Mr. J. B. Irving, the patentee, thus summarises his improvements:—

The camera is made square, with double-extension swing-back rising-front reversing arrangement, and is fitted with a shutter, which shutter can be fitted behind the front of the camera and inside the bellows. The kind of shutter I prefer is hereafter described. The bellows are attached to the sides of the frame, instead of two wings at right angles, as usual, that the folds may not cut off the light from the edges of the plate, the back folds of the bellows are larger than the front folds, and are made more pliable, so as to open fully before the others begin to unfold. The dark slides are made square, and are so arranged that they can be put in the camera to replace the ordinary reversing back, and can be used either vertically or horizontally. The front of the camera may be supported on the baseboard (which baseboard can have the usual rack-and-pinion movement) by a brass or other stirrup having slots, in which pins on the adjusting rack fit and hold the front of the camera in the right position. The front of the camera has also the usual rising-front arrangement. The back of the camera is formed so as to swing backwards or forwards by means of a strut of sheet metal fastened at one end to the baseboard, and bent at right angles in a plane nearly perpendicular to the side of the strut, thence again perpendicular at right angles to this plane, and supplied with a long slot having a sudden hook bend and a second slot. A screw pin in the frame works in this slot, and there can be several hooks in the slot, and thus several different points at which it comes to a full steady stop. By, however, allowing the pin to round the projection, it can run into the next slot, and thus the swing back opens still further. As the pin arrives at the end of the slot, it is held from going further by the projection. The lens has the usual iris diaphragm attached to it, but, instead of having the setting lever which actuates the diaphragm project through the side of the casing, I place it within the hood of the lens mount at the front, as by this means the lens may be more deeply or entirely sunk within the camera, and the lever is easier of access.

I also arrange at the back of the camera a focussing screen, which may be made of any suitable material, such as celluloid or the like; but, as the screen is liable to bend if made of pliable material, I place a light frame, fitted with vertical and horizontal bars, against the screen, and which forms a kind of grating. These bars serve to keep the centre of the screen straight, and also can be used instead of the vertical and horizontal lines, which are usually ruled on focussing screens.

A TRIP TO NORTHERN ITALY.

I took a trip to Venice two years ago, but it was a very short one; so, like Oliver Twist, I wanted some more of it. This year I was able to manage another visit, breaking the journey at Milan and Verona.

Except the celebrated Cathedral, there is not much in Milan in the way of architecture, which is the line I mostly work at; but at Verona there is an abundance of subjects—the Arena (a Roman amphitheatre), several churches, Arche degli Scaligeri, Piazza Erbe, and the curious water mills on the Adige. These last are unlike anything I ever saw elsewhere; they consist of three large flat-bottomed barges, two of which are fastened close together, and the third fastened to the other two by large beams, but about its own width away from them. A water wheel works in the space between, the mill being on a couple of barges. The whole affair is moored out in the stream, and connected by a gangway with the shore.

With the exception of S. Marco and I Gesuiti, the interiors of the churches in Venice are not very good subjects for photographing, St. M. della Salute in particular, picturesque as it is outside, being too short (it is polygonal) and also very lofty, so that no part of the dome can be got in. I Gesuiti, as it is always called—I forget its real name—is, like the other churches of this Order, remarkable for good work and laviah ornamentation. It is lined with white marble and inlaid, but the general effect is not very pleasing. I Frari has a very handsome exterior, which is the more remarkable from its being almost entirely built of red brick.

Many of the oldest churches in Venice have been closed as such, and sold, being used as stores; S. Gregorio is one of them, and is now a Government wine store; the abbazia of it is picturesque, but somewhat spoilt by a quantity of stone rubbish being deposited in the middle of the court.

Most foreign churches are to some extent picture galleries. I am not an artist, and do not know what pictures are good and what are not, but I know what I do and what I do not like. The good pictures are freely mentioned and praised in the guide books, but there are some which are peculiar, and which are only mentioned—neither praised nor described, *i.e.*, a *Last Supper*, by Cesare da Conegliano, in S. Apostoli. There is an interesting bas relief in S. M. dei Miracoli, which "Baedeker" says

is a copy, with variations, of Leonardo da Vinci's *Last Supper*, but which, I have been told in Italy, is the original from which he got the idea.

I took the opportunity, whilst at Venice, of going down to Ravenna, one of the most interesting places in Italy. Here are churches, some of which were consecrated in the fifth and sixth centuries, and are still in good repair. The mosaics in some are wonderful, especially those in the Batistero and S. Apolinare Nuovo; but, owing to some of them being in domes (the two baptistries are practically nothing else), it is necessary to have some means of photographing vertically, either by using a prism or by pointing the camera upwards.

On the way to Ravenna I had to wait some hours at Ferrara, also an interesting old place, but in a different way; I was unable to take any pictures there, as a very wide-angle lens is necessary.

A "permisso" is usually necessary for photographing the interiors of churches in Italy, and, to enable others to avoid a considerable amount of trouble which I had to take, I will say how it ought to be obtained.

In Venice you have to buy a stamped paper, valued sixty centesimi, and on this the application has to be written. In my case an official wrote it — in Italian — for me, and I got the permesso the same evening without any further payment. The office (Ufficio Regionale par la Conservazione dei Monumenti del Veneto) is on the first floor of the ducal palace, diagonally opposite the Scala dei Gigante. For photographing at Ravenna application has to be made to the Ufficio Regionale per la Conservazione dei Monumenti di Antichità, Bologna. I made mine by a reply prepaid telegram, and got the permesso in this case also without having anything more to pay. One condition on which a permesso is granted is, that you have to send three prints from each negative to the office.

In Venice there are at least two places where plates and apparatus can be bought, and where a dark room can be hired, viz., C. Acerboni, Ponte Cavalletto, 96, and Antonio Trauner, Merceria, 724. The charge for using the dark room is, at either house, two lire an hour.

I went from London *viâ* Newhaven, with Cook's return ticket, available for forty-five days, the cost of which, second class, was 8*l.* 13*s.* 6*d.*, and which enabled me to break the journey wherever I chose in Italy.

It is advisable, when travelling by rail in Italy (1) not to have much luggage, as there is none carried free except what you take in the carriage with you; (2) to have really good portmanteaux and locks, as the guards have the reputation of opening luggage and helping themselves; (3) not to have large trunks; (4) to insure all your baggage.

J. E. Gubbins.

The Inquirer.

*** *In this column we shall, from time to time, print questions that may be addressed to individual contributors to our pages, or such as are sent to us with the view of eliciting information from a variety of sources. We invite the co-operation of our readers in rendering this feature of the* Journal *useful and instructive.*

Lens Query.—If "Non-mathematical Reader" will bear in mind that the size of the object and the size of the image bear the same relation to one another as the distance of the object and the focus of the lens, he will not have much difficulty in working out his calculations.—J. E. Clark.

Utilising Calomel.—W. H. E. writes: "I have a considerable quantity of calomel for which I have no use. Can I in any way adapt it for use in intensification by converting it into corrosive sublimate? I have added hydrochloric acid to a portion of it, but that appears to have no action. Can any of your chemical readers assist me?"

Unmounting Gelatine Prints.—J. W. H. says: "In reply to 'Albumen,' let him treat his prints in the same manner as for crystoleum painting. Squeegee the thoroughly soaked prints to glass, but without any adhesive, and proceed to remove the mount by scraping and rubbing until no particle of unevenness remains. Then reapply fresh mountant and transfer to scrap book."

Fixing Prints.—C. P. R. says: "Having read the report and discussion of Mr. Haddon's Convention paper, I should much like replies to the following queries:—To fix a batch of prints with a fifteen per cent. solution of hypo for fifteen minutes, what method do you advise for gauging the sufficiency of the solution requisite in order to have the necessary quantity for the work to be done? and what, supposing just sufficient solution had been used, should be the strength left after fixing? Whose hydrometer is most suitable for taking the specific gravity of the aqueous solutions used in general photography and would it be a reliable method to test with an hydrometer the strength of solutions before using?"

Washing of Prints, *re* the discussion upon Mr. Haddon's paper.—Alpha says: "Will Mr. Pringle kindly oblige by stating what in his opinion should be the strength of the fixing solution; the temperature of same; and the reasonable time required. Answers from able, experienced, and successful workers, detailing their *modus operandi*, are most valuable. Some recommend only two ounces hypo to twenty ounces water, made alkaline with ammonia; others, I see, four ounces hypo."

Non-coagulable Albumen.—E. Freeman asks: "Can you give me any information, or tell me where I can find it, of a peculiar form of albumen which possesses almost diametrically opposite properties to those of ordinary egg albumen? If I remember rightly, it is not coagulated by heat, and is soluble in alcohol. I have read a description of its properties somewhere in the Journal or Almanac, but how long since I am unable to say; but it is probably some years ago, for I cannot find the reference."—We cannot at the moment refer our correspondent to the number of the Journal containing the description, but it appeared, we believe, in leader form several years ago, and we will endeavour to find it.

Insensitive Collodion Emulsion.—"I have been told," writes Halifax, "that an unwashed collodion emulsion, containing free bromide, is insensitive to light, until the excess of bromide is removed by washing. If this be really the case, is it not possible to coat the plates in daylight, and wash only in the dark room? Also, if such be the case, there does not appear to be any need to take very special care of the bottle containing the emulsion. I see that Mr. E. Sanger Shepherd, in last issue, speaks of coating in a *good* light, so as to be able to freely examine for defects before washing the plates. This would appear to answer my question; but what *is* a 'good' light? Daylight?" It is an easy matter to try the experiment, but *cui bono?*

Unmounting Gelatine Prints. — J. S. writes in reply to "Albumen": "If 'Albumen' will attack the prints from the rear, he will, perhaps, have better success than from the front. Soak mounts and all in cold water until the different layers of the cardboard can be removed piecemeal, leaving only the front sheet of fine paper that forms the surface in contact with the print. If every particle of rough cardboard and mountant be gently rubbed off with the ball of the finger without injuring the surface sheet, which is easily done if a little care be exercised, it will be needless to remove the latter, and it may be trimmed to the size of the print and remounted with it. Or it may be separated by carefully damping the back with a sponge and hot water until the gelatine is melted, the face of the print being laid smoothly in contact with a sheet of wet glass."

Lens Query.—In reply to "Non-mathematical Reader," I think he has not completely stated the conditions of his first problem. Distance and *size* of object and focus of lens being known, it is easy to arrive with sufficient approximation for all practical purposes at the size of image. Let D be the distance and S the size of object, *f* the focus of lens, and *s* the size of image. It is then a simple rule-of-three sum—: : D : *f* : : S : *s*. For absolute correctness, *f* would represent the actual conjugate and not the principal focus, so that, except for objects at some distance, the error arising from variations in the camera extension would be considerable. For the second problem the formula would be—*s* : S : : *f* : D, the same remarks applying. The results obtained are sufficiently accurate for use in the portrait studio, taking the principal focus as *f*, but for copying it would be necessary to go into further calculations to find the true *f*. — Forest Hill.

Transparent Carbon Tissue.—Carno says anent some recent discussion on carbon printing without transfer: "Now that celluloid and other transparent mediums are so easily obtainable in extremely thin sheets of considerable strength, I wonder that some of the makers of carbon tissue do not utilise these substances in place of paper as the support at once 'temporary' and 'permanent.' The printing could then be done through the support which, if thin enough, would not interfere with sharpness, and the development would proceed in the ordinary way, just as the development of a film negative, the result being finally squeegeed on to paper, glass, or opal, as desired, or, better still, direct on to a suitable carbdoard mount. As far as I can see, there need be no great difficulty in the way of carrying out the idea; but, of course, there would be a difference in cost, which would be more than compensated for

by the saving of trouble in use." Swan's original patent was for a tissue on this principle, namely, bichromated gelatine spread upon collodionised glass, and stripped after drying. The extreme thinness of the collodion film ensured perfect sharpness of the image, but, at the same time, necessitated the mounting of the tissue during development. It is questionable whether the colour and thickness of the modern film materials would permit of their use in this direction.

Our Editorial Table.

Jahrbuch für Photographie und Reproductionstechnik.

Wilhelm Knapp, Halle a/S.

The volume for 1896, edited by Dr. J. M. Eder, is a valuable addition to the photographic literature of the year. The high character of this annual is fully maintained, and the articles, written by many of the most competent authors of the day, record the progress of photography in all its branches since the compilation of the previous volume. We notice several very interesting and valuable papers on orthochromatic and colour photography, and many others on photo-mechanical and kindred subjects, by leading men in these branches. All recent improvements in lenses and apparatus are recorded and described, and there are many articles on printing papers, developers, and other subjects of special interest in ordinary photographic practice. Among the numerous contributors to the work we notice the names of A. Albert, J. J. Acworth, A. C. Angerer, Dr. Paul Czermak, C. H. Bothamley, G. Fritz, C. P. Goerz, E. von. Hoegh, Dr. J. Husnik, A. Lainer, R. Ed. Liesegang, Dr. P. Rudolph, A. and L. Lumière, L. Schrank, E. Valenta, Dr. Vogel, and E. J. Wall. A collection of prints at the end of the volume illustrates the present position of photo-mechanical work and colour printing.

Stamp-sized Photographs.

A. Seaman & Sons, Chesterfield, Ilkeston, and Matlock.

In the Journal of May 29 we described a printing frame, the invention of Mr. Seaman, for making stamp-size photographs direct from larger originals. By means of this frame, twelve photographs, each one inch by three-quarters of an inch, are printed from a small negative on a sheet of paper three inches square. The frame, as our readers will gather from the description (see page 347), is a very simple piece of apparatus, and should be found useful by those undertaking the production of these tiny photographs, which, as we have lately more than once taken occasion to remark, appear to be growing in popularity.

Of the quality of the results so produced. Messrs. Seaman have enabled us to judge by sending us an assortment of specimens, including some stamp-sized reproductions of our own portrait. Very pleasing little photographs are producible in this manner, and we are not at all surprised to learn that Messrs. Seaman find great demand for them. They appear to be executed on surface bromide paper, and are qualitatively all that could be wished for.

News and Notes.

The following are the awards in the last competition for amateurs' negatives on Gem plates:—1st prize, C. A. Morgan, Grange-road, Alloa, N.B.; 2nd, Miss H. Phillips, Woodland Park, Colwyn Bay; 3rd, Miss E. S. James, Hillside, Newton Abbot; 4th, F. W. Smith, 16, Parson's-green, Fulham, S.W.

The Photographic Club.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock on Wednesday evening, the subject of discussion will be *The Relative Results of Different Developers in the Same Series of Exposures*. Visitors are welcomed by the members.

Gardens of Taste for Town Workers.—In connexion with the "One and All" Flower Show at the Great National Co-operative Festival this year, will be a unique exhibition of photographs and other illustrations of suburban and rural gardens and scenery. The competing views strikingly show what a wealth of floral adornment may be effected in a small space. Perhaps the capabilities of photography as a means of illustrating sylvan and garden scenes, and bringing out the nicest gradations of light and shade, have never been so well displayed as in some of the specimens which will be on view at this exhibition at the Crystal Palace on August 22.

An amusing and totally unrehearsed incident took place at Lord and Lady Salisbury's garden party to Li Chung Tong at Hatfield, on Saturday, which is worthy of being recorded. The ubiquitous photographer, without whom no *al fresco* function is complete, had arrived, and immediately pointed his camera "full on" at the distinguished Chinaman; but, just as the crucial moment arrived, and Lord Salisbury, and his guest were placed in position, the Prime Minister's pet boar-hound, indignant, possibly, at being excluded from the group, make its way to the front, convulsing every one by the vigour with which it wagged its enormous tail. The development of that picture will be looked forward to with interest, as it is doubtful whether even the timely application of the X rays could have reproduced the nether limbs of the noble Marquis and the Chinee, which the waving of the hound's tail so successfully hid from view.

The Solar Eclipse: Observations in Norway a Failure.—No results of any value were obtained of the solar eclipse, notwithstanding the extensive equipments of the Norwegian and Swedish parties. On a hill four hundred feet high to the north of Vadsö was Professor R. Copeland, Astronomer Royal for Scotland, with a forty-foot telescope. Close by was Dr. A. A. Common, F.R.S., President of the Royal Astronomical Society, with elaborate arrangements for photographing the corona and its spectrum. Lower down were more than fifty observers on an island opposite the town, and as far as was known, Professor J. Norman Lockyer (editor of *Nature*), with more than seventy observers, was at Braeshavn, on the opposite side of the fiord. A Russian party was located further east. All the observations, however, were rendered unsuccessful by a patch of cloud. The sun was seen for a few moments through clouds, but was quite obscured during totality. A dispatch from Bodö, Norway, received by the *Politiken*, states that the eclipse of the sun was well observed there, the sky being clear. A telegram from Bodö, received to-night, states that a photographer from Flensburg has taken eleven photographs of the eclipse at Bredvig on the Skjerstad Fjord, where it was clearly seen.

Big Photographs used as Wall Paper.—*Tit Bits* says: "A fashionable photographer of Regent-street has just communicated to us some really astounding facts concerning the growth of his profession. It seems that the latest development of taste in house decoration is the substitution of immense photographs for the ordinary ornamental frieze. This extraordinary fashion has its origin in a rather remarkable circumstance. One evening a large party of ladies and gentlemen, bound for a fancy dress ball, alighted at the establishment of our informant in Regent-street for the purpose of being photographed in costume. They arranged themselves in a more or less chaotic group, so that the photographer, who chances to be a painter by profession, was in despair, and ultimately asked his troublesome clients to march through the room and perform the graceful movements of the minuet. To photograph as many as sixteen people so engaged may sound impossible, and no, doubt, it would be so to the ordinary (*sic*) photographer. The great man in Regent-street, however, has discovered and patented a process whereby not only is the electric light applied to the purposes of photography, but all the rays are converged upon the sitter. Bringing his process to bear on the occasion alluded to, the artist succeeded in producing an admirable photograph of the whole party; it measured three feet in depth, and no less than sixteen feet in length. No sooner were copies of it reproduced than they were utilised forthwith as friezes for fashionable drawing-rooms, and in this way started a very unique mode. At the present time photographic wall papers have become quite an aristocratic craze, and it may, perhaps, be necessary to mention that our informant's clients are chiefly drawn from the very highest circles of society."

Ribbed Glass Windows.—Ribbed window glass is making its way very rapidly in America, and the reasons for its adoption are many and practical. With the old form of glass, both in fair and cloudy weather, the direction of the light entering the window is downward at an angle of about 40° or 50°. Thus the brightest portion of the room is the floor immediately in front of the window. The floor (says a contemporary) is not, as a rule, a very effective reflector, as a large amount of light is absorbed by it and lost. Early in the morning and towards the evening the angle of incidental light with the horizon is less; therefore the light penetrates through into the room, but the wall spaces between the windows get very little of it. If panes of ribbed glass are substituted for the plain glass, the bright spot in front of the floor disappears, and the entire walls and ceilings appear of the same brilliancy. The action of the ribbed glass is somewhat prismatic, the greater part of the light being reflected and spread out into a fan-shaped beam, which lies in a plane almost perpendicular to that of the glass and the direction of the ribs. It has been discovered that the effect of having the ribs horizontal is to give an increase of light in the middle of the room, and a decrease at the sides, whereas the vertical ribs give an increase at the sides and a decrease at the centre. The diffusion of heat is effected in the same way; there is no point where the heat rays stream directly in when ribbed glass is used, thus it is cooler than the plain glass by from 4° to 15° Fahr. The ribbed glass is itself hotter, however; thus the temperature of the air is much the same in both cases. Several large factories in America have been fitted up with this ribbed glass, and the effect is said to be in each case extraordinary. In cases where rooms were overlooked by other buildings the increase in light is really surprising. A large new establishment in Boston has been treated in this way, and the working people engaged there all speak with the utmost satisfaction of this new means of lighting.

Colour Photography: Mr. G. G. Bullmore's Challenge.—It will be remembered in our last issue Mr. Bullmore challenged us (on account of a friend) to produce within one month such photographs in colours as were described in the previous issue. Of course it will be plain to Mr. Bullmore that we are not in a position to produce such photographs without the permission of Mr. Wallace Bennetto. Now, this gentleman declines to give his consent on several grounds. Firstly, that he regards the whole letter as based on the implication that he does not speak the truth. This, he says, puts the matter entirely out of court as far as he is concerned. Secondly, that he is

not aware that it is usual to meet any inventor with what, in his opinion, is a common street bet. Thirdly, that he does not feel bound to consult anybody as to when or how he shall prove the validity of his discovery. He has stated he will hold a demonstration during the season, when he expects to satisfy even the Thomas-like friend of Mr. Bullmore. Now, we quite understand that those who have not seen the pictures are sceptical; we were ourselves. The description which we inserted was only a result of what we have seen. We do not pretend to be professionals, but we are most certainly of opinion that Mr. Bennetto's results are not obtained by any hand work. This opinion we find, without exception, held by those who have seen them, and, we may truthfully say, disbelieved by nearly all who have not! It does seem rather curious, it is always hard to believe that a person residing in one's native place has made a discovery. If he lived at Plymouth or London, doubts would possibly not arise. Mr. Bennetto declines to let us accept the challenge respecting the 20*l.*, but, if Mr. Bullmore will make the suggestion reciprocal respecting the rest of his offer, we will accept, *i.e.*, we will undertake that the photographs as described shall be produced on or before November 1 on condition that Mr. Bullmore will present a bound volume of the *Newquay Notes and Directory* to the British Museum, containing reference to the challenge by Mr. Bullmore or ourselves, and we will, if our promise is unfulfilled, present those numbers bound to the British Museum. We are quite willing to extend our offer so as to cover the Newquay Institute and Reading Room.—*Newquay Visitors' Notes.*

Recovery of Silver and Gold from Photographic Residues.—The *American Druggist* translates from the *Neueste Erfindungen und Erfahrungen* an original contribution by Weidert, as follows:—"Analysis of finished photographs shows that only a very small portion of the gold and silver used in their preparation remain in the finished print, by far the greater portion of the metals being retained in the baths. The methods of recovery of silver residues vary with their character. The silver from old fixing baths can be recovered in the simplest manner. By hanging strips of copper or zinc in the baths, the silver will be deposited on the strips in a greyish black powder or in small leaflets of a metallic lustre. This method, however, is tedious and extravagant, since a large portion of the silver remains in this solution. A somewhat better method is to agitate the bath after the addition of zinc dust, and then filter off the precipitate, wash, and then treat with diluted sulphuric or hydrochloric acid, in order to dissolve out the valueless zinc. This process, also, is not particularly to be commended. It is generally customary to precipitate the silver with an aqueous solution of potassium sulphide, and drain the brownish black sulphide of silver on a muslin filter and dry it. In order to reduce this to silver, it is fused with calcined soda in a porcelain or graphite crucible and poured upon an iron or marble slab. The sulphide of silver can also be roasted in the atmosphere, then mixed with three or four parts of potassium nitrate, and introduced carefully in small portions into a glowing crucible. In order to recover the silver from the paper clippings, &c., which have not been 'fixed,' the paper residue should be cut into small pieces and put for two hours into a bottle where the old fixing bath is kept. This bath is then filtered and treated as above directed. Since all photographic silver paper contains, in addition to the silver chloride, easily soluble silver nitrate, the first wash water from the toning in particular should be collected, and the silver precipitated by the addition of hydrochloric acid and sodium chloride. After drying, this should be reduced in the same manner as the silver sulphide, by the means of potassium or sodium nitrate. One may also pour over this precipitate a five per cent. solution of hydrochloric or sulphuric acid, and then hang in the solution a piece of zinc, whereupon the silver is thrown down in the metallic form. Gold is generally precipitated from the baths by addition of hydrochloric acid and a solution of ferrous sulphate. The gold is thrown down as a brownish red powder, which should be washed well and fused. Occasionally ammonium chloride is added in excess to the toning bath with some hydrochloric acid. The gold then precipitates out after a short time (if in a warm place and particularly in light) in the form of metallic glistening scales."

The Battle of the Baths.—I have already spoken of the advantages of the combined bath, but, like most other questions, it comes up again and again, and at the present time is being fought as hard as ever. Nor is it difficult to understand why it should be so. Although photography is essentially a chemical operation, photographers generally, professionals as well as amateurs, know little or nothing of chemistry, and unthinkingly, or rather thinking wrongly that the makers of sensitised paper know best what is best for their paper, employ for fixing and toning messy mixtures that fill the pores of the paper with the seeds of decay, that sooner or later must induce fading, and that neither hypo nor water will remove. In the too frequently recommended messes, including hypo, alum, gold, lead, &c., and especially when salts of silver are added by the immersion of prints in the solution, decompositions and recompositions occur to such an extent as to defy even an accomplished chemist to say what may be their ultimate composition, or what may or may not be left in the finished print, and therefore no photographer who has any respect for his character, or, if he be a professional, who wishes to retain his customers, should ever use them. To the professional photographer who tones and fixes a large number of prints daily, the question of convenience and other advantages of the combined bath are not very material; but to the amateur who prints only a few copies now and then they are very great. He may, for instance, make up enough to last him for a whole year; pour into a tray enough to well cover the few prints he wants to fix and tone, get any colour he desires, and then return it to the bottle to be ready for the next time; and that, provided the bath has been properly made, with the perfect certainty that his prints are in every way as good as if he had employed the separate solution method. "The battle of the baths," then, is simply the battle of the two sides of the shield. An improperly made combined bath—and almost all that are in present use are such—is an abomination, but one that is properly made is more convenient, more economical, gives equally permanent and equally beautiful results, and is in every respect better than any system of separate toning and fixing. I have experimented with almost every brand of printing-out paper that has been introduced, and say most emphatically that almost any desired tone from warm brown to a purplish black may, with suitable negatives and suitable printing, be reduced on any or all of them in a bath containing only sodium hyposulphite and gold. An exact formula is a matter of little importance, so long as there is sufficient of the one to fix and of the other to give the colours, the difference between weak and strong solutions being simply a question of time. The formula I generally employ has served me faithfully for over forty years, and is as follows: Sodium hyposulphite, 1 ounce; gold chloride, 1 grain: water, 8 ounces. Dissolve the hypo in six ounces of the water and the gold in the remaining two ounces. Neutralise the latter with sodium carbonate and add it to the former. The prints may be placed in the bath either with or without washing, but I almost always do the latter, and when the desired colour is reached, which may be in a few minutes, or in an hour or more, depending on the temperature and the colour desired, transferred to a solution of common salt, say, a handful to the gallon. The bath, as I have said, will keep indefinitely, but must be discarded as soon as the gold is exhausted, which will probably be after having toned a sheet and a half of paper; say, twenty-five cabinets for the darker tones, and half as many more in warmer colours. To those who may not have the convenience, or who do not care to take the trouble of weighing and measuring, the following formula will be acceptable, and give a combined bath sufficient to fix and tone prints equal to from four hundred to six hundred cabinets: Sodium hyposulphite, 1 pound; gold chloride, 15 grains; water, 1 gallon. Dissolve the pound of hypo as it comes from the stock house in the water, leaving out an ounce or two in which to dissolve the 15-grain bottle of gold, which, when neutralised by sodium carbonate, add to the hypo solution.—John Nicol, in *Outing.*

Patent News.

The following applications for Patents were made between July 29 and August 5, 1896:—

Cameras and Stands.—No. 16,544. "Improvements in Photographic Cameras and Tripods or Stands therefor. J. E. Thornton and E. Pickard.

Magic Lanterns.—No. 16,599. "Improvements in Magic Lanterns and Objects therefor." J. H. Pepper.

Lenses.—No. 16,602. "An Improved Protective Device for the Dispersing Lenses of Light Projectors." Communicated by Elektricitats-Actiengesellschaft vormals Shuckert & Co. Complete specification. H. H. Lake.

Plate Forceps.—No. 16,866. "Photographic Plate Forceps." H. Parson.

Film-holder.—No. 16,868. "Photographic Film-holder." H. Parson.

Screen Kinetoscopy.—No. 17,049. "An Improved Apparatus for Taking Photographs in Quick Succession and Projecting them on a Screen." G. H. Harrison and T. J. Harrison.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

August.	Name of Society.	Subject.
17	Bradford	*Printing and Toning.* F. Nicholson.
17	North Middlesex	*Elementary Composition.* F. L. Pither.
18	Birmingham Photo. Society	Excursion: Lilliesball Abbey, Shropshire. Leader, W. B. Osborn.
18	Brixton and Clapham	Ordinary Meeting.
18	Hackney	Address by the President.
18	Oldham	Excursion: Queen's Park Museum. Leader, J. Greaves, jun.
19	Borough Polytechnic	Open Evening.
19	Photographic Club	The Relative Results of Different Developers on the Same Series of Exposures.
22	Borough Polytechnic	Excursion: Otford, or Bromley and Orpington.
22	Croydon Microscopical	Conversational Meeting.
22	Hackney	Exc.: Dagenham. Leader, W. Hensler.
22	Leytonstone	Excursion: South Weald. Leader, G. U. Haslam.

PHOTOGRAPHIC CLUB.

August 5,—Mr. Crofton in the chair.

The Hon. Secretary read a letter from Mr. Cowan. He said that he was now beginning to get about with the aid of a crutch and stick, and that he hoped soon to be able to dispense with this assistance. He enclosed a letter from Mr. Montagne Troup, a member of the Club, who had recently gone to Western Australia. The letter, which was of an interesting and chatty character, was read to the meeting by the Hon. Secretary, who was directed to thank Mr. Cowan for his kindness in forwarding it on. The Hon. Secretary then read a letter from Mr. Cole, of Barnet, calling the attention of the Club

to a statement (which was published in a report of the Club's proceedings) that a model of a rising and falling front, shown by Mr. Foxlee and presented to the Club by Mr. George Hare, was the same as Mr. Cole's invention.

The members of the Club present, including Mr. Foxlee, were unanimously of opinion that this was not so, and the Hon. Secretary was instructed to write to Mr. Cole to this effect.

A short discussion then took place upon the use of small cameras and the making of enlarged negatives.

Mr. CHARTERS WHITE asked the best method of enlarging from a quarter-plate negative which he produced. He said he had a four-and-a-half-inch condenser, and wanted to produce the best possible result, so that the editor of a paper could use it for reproduction purposes in his journal.

Some of the members examined the original negative and the enlargement already produced by Mr. White, and, having criticised them, offered suggestions.

MANCHESTER PHOTOGRAPHIC SOCIETY.

DESPITE the predictions of the morning's paper weather prophet, and the gloomy appearance of the weather, about twenty members with their friends assembled on the afternoon of the 8th inst. at London-road Station for the last outdoor meeting of the season. The destination was Bramhall, and the party alighted at Cheadle Hulme station and proceeded across the fields to Bramhall Hall, permission to photograph being kindly given by the owner, Mr. C. H. Nevill. The exterior unfortunately was only available, but, despite a few showers, cameras were soon at work on one of the best specimens of black-and-white in the district. The Hall stands on the top of a grassy mound sloping gradually to a rippling stream, which has been artificially made to form a small but artistic lake. The Hall was originally built about the time of King Edward IV., but Mr. Nevill has made many restorations, of which he is his own architect. After everything had been taken that could be taken, the party traversed a pretty woodland path to a farm, where good fare was provided for the workers and those who looked on. Leaving Bramhall Station about half-past seven, Manchester was reached at a quarter past eight, closing about the pleasantest season of outings the Society has ever held.

Borough Polytechnic Photographic Society.—On August Bank Holiday over forty members of the above Society (including many of the fair sex) visited the ancient historical city of St. Albans in the form of a picnic party; and, favoured with fine weather, a most enjoyable day was spent, both photographically and otherwise. Immediately upon arriving at St. Albans, soon after ten o'clock, the whole of the party visited the old Abbey Church, one of the finest buildings of the kind in the kingdom, consisting of a nave with western porches, aisles, transepts, choir with aisles, saints' chapel, eastern Lady Chapel, and a chantry chapel on its south side, with a central tower containing eight bells (of which the tenor weighs thirty cwt.) and a sanctus bell. The central parts are most ancient, and are built of Roman bricks from the ruins of Verulam. Despite the constant capping of the lens, in consequence of the numerous people passing backwards and forwards, and the many other difficulties one has to contend with in photographing interiors, some excellent results were obtained, and we were kept fully occupied until past the appointed hour for dinner, which was partaken of on the meadow of a local farmer, and full justice was done to the excellent and plentiful supply of provisions provided. After dinner a brake was chartered, which conveyed many of the party through some splendid scenery as far as Hatfield and back, frequent stoppings being made for those who took their cameras with them. The remainder of the party, who did not go for a drive, contented themselves with scouring the surrounding country in search of "bits." What is said to be the oldest inhabited house in the kingdom (and its appearance certainly goes to favour the statement), and known as the Fighting Cocks, was the object of several of our party. Tea was served in splendid style at six o'clock, after which most of the party, who had by this time exposed their last plate, indulged in some games, &c., whilst a second party were driven to Redbourn, thence to Harpenden, past Rothamsted Park, and back to St. Albans. Little was done in the way of photography, as the light for the most part was now very bad; given a good light, there is a heap of work for the amateur along this route. Upon the second brake-party returning, a concert was held on the meadow, which fittingly wound up what was unanimously voted "the most successful and enjoyable outing of the season." We are now preparing our winter session syllabus, and the Secretary will be glad to hear from any one who would be disposed to help us with a paper or demonstration on any subject on any Wednesday or Saturday evening. Communications should be addressed to 103, Borough-road, London, S.E.

North Middlesex Photographic Society.—August 10, Technical Meeting, Mr. F. W. Cox in the chair.—Mr. WALKER reported on the outing to Cambridge on Bank Holiday. He said eight members attended and spent a very enjoyable day. They photographed in several of the colleges, and were kept interested by Mr. Pither by his descriptions of the architecture, &c. Messrs. Cox, Mattocks, and Taylor brought up some results they had obtained on Venus paper, on which a demonstration had been given by Mr. Milne at a previous meeting, and the prints were much admired. Mr. COX said a member had told him of a dodge for obviating silver stains on an unvarnished negative, which consisted of using a sheet of *papier minéral* between the negative and print. He found no loss of definition resulted. Mr. MACINTOSH described Wellington's stripping film, and passed round a negative he had stripped. He also said a good way to clean off the emulsion from spoiled negatives was to immerse one in a solution of potassium bicarbonate, and transfer to one of weak acid. Carbonic acid gas was given off in the film, and that loosened it, and it came easily away. He also exhibited a Krugener's book camera. In the competition for the prints taken at London Colney, Mr. Smith was placed first and Mr. Lisett second.

Correspondence.

☛ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

NATIONAL ASSOCIATION OF PROFESSIONAL PHOTOGRAPHERS.

To the EDITORS.

GENTLEMEN,—I take exception to a portion of your paragraph *re* the N.A.P.P. You say: "Of business tending to advance the profession, or even of individual members thereof, the Association appears to have done none at all."

Now, I could give you the names of large dealers who, up to the time of the Association, did business extensively outside the profession, who now deal solely with photographers. I enclose you a letter just received, not for publication, which is a case in point.

As to benefiting individual photographers, I may say my correspondence alone has been very considerable, and I fancy, beneficial; any how, repeated letters of thanks to me ought to be a proof of benefits received—please understand I should not have been brought into communication with my correspondents but for the N.A.P.P.

United action among the profession scattered so wide apart is difficult, as the dealers soon found, when they attempted a similar association and failed.

No, the Association may not have come up to expectations—but it has done much good in the past, and this in spite of the indifference of the members of the profession generally.—I am, yours, &c.

9, *Baker-street.* THOS. FALL.

EFFECT OF THE X RAYS ON THE SKIN.

To the EDITORS.

SIR,—Mr. Dunmore will do a distinct service if he investigates further the subject of his short note.

Of course, the deleterious effect on the skin of certain developers and solutions is well known, though not thought so much of as it might be. In the anxiety to get results with the New Photography one is apt to neglect precautions which otherwise would be taken; at least, that is my experience. But the least relapse to a condition of eczematous trouble, analogous to that described by Mr. Dunmore, and which is practically identical with the effects produced by the unguarded use of certain developers, will be a very sufficient warning.

With regard to *X rays*, is any one yet capable of giving an authoritative opinion? Certainly we see conflicting statements. If they exert a harmful effect on the fingers, why not upon the eyes or nose? In my own work, so far, I find the hands and fingers least exposed to the rays. In the first place, they are usually encased in a pair of rubber gloves; secondly, as the current is not switched on until the subject is arranged in position—the usual practice, I imagine—they are practically out of range during the whole of the exposure.

If the gentleman referred to by Mr. Dunmore has at any time during the past month exposed his digits *but once or twice* to the action of one or other of the strongly alkaline developers so popular (and useful) at the present time, I have no doubt that is the cause of his trouble.—I am, yours, &c., J. PIKE.

Nottingham, August 7, 1896.

MOUNTING UNALUMED PRINTS.

To the EDITORS.

GENTLEMEN,—I see, by last week's edition of THE BRITISH JOURNAL OF PHOTOGRAPHY, that you mention in an article on "Prints," that it is almost impossible to mount prints that have not been alumed. This is just the reverse of my experience, and, ever since its commercial career, I have used it. I tone, fix, and wash in the usual way, except that I never use a *rotary washer*. I have up to the present time used some two hundred tubes of gelatine chloride paper with a shiny surface, and have never used an ounce of alum, or lost a print through the heat dissolving the films or by frilling. A scratched print is a *rara avis* with me, and so it would be with any one who takes care with the manipulation in the various stages of washing, &c. My priots are *trimmed when dry after toning and fixing, not when they have left the printing frame.* I mount them with a rubber roller, about two inches in diameter, and they never crack or peel. Of course, I may be wrong in going against so good an authority, but my experience certainly tells me different.—I am, yours, &c., LIONEL P. G. DUNCROFT TAYLOR.

Thames Bank House, Mortlake, August 7, 1896.

OPACITY OF PLATES.

To the EDITORS.

GENTLEMEN,—Mr. A. L. Henderson, in last week's JOURNAL, asks "Why is a gelatine plate more opaque when wet than dry?"

Though not presuming to give the real scientific reason (I know nothing of science and chemistry), I venture to suggest that it might be accounted, up to a certain degree, to the hygroscopic property of gelatine, which, according to Captain Abney, in cold water, swells up and absorbs from five to ten times its weight of water.

Hence the increase in opacity—due to the greater thickness of the film. The action of drying rids the gelatine of water, and makes the film thinner and more transparent. Whilst engaged in emulsion-making I have noticed sometimes a freshly coated plate, which seemed to me thick and greasy, come out of the drying cupboard considerably reduced in opacity.

To ascertain if my surmise is correct, I should coat a plate with gelatine containing some colouring matter, such as Payne's grey, Chinese ink or sepia, and, after drying, compare it with another plate wet.—I am, yours, &c., ALBERTO GARIBALDI WHITE.

Villa Valentino, Isola di Capri, Golfo di Napoli, Italy, August 5, 1896.

ART *VERSUS* MECHANICAL PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—Seeing a letter in your JOURNAL, by Matthew Surface, entitled "Art *versus* Photography," asking what all these cameras and processes lead to, may I make a few remarks? Is it not to bring the beautiful into the homes of our fellow man? and then comes the question, What is the beautiful? and how are we to make our works a thing of beauty? Well, for some few weeks, I have been writing a pamphlet on "What is Beauty?" illustrated, but I have not yet got it in print, but when printed I should be glad to send it to any photographer desirous of having it.

It seems to me that photographers of the future should make it their business to be artists, if they wish to succeed as photographers. Well, how is it to be done? In my early years I was exceptionally favoured in having the means and time to study, both at the South Kensington Art Schools, gaining many prizes there, also seven years student of the Royal Academy of Arts, and practising, with success, photography; and the result of art training is that it teaches us to see

> "There's a beauty all around our paths,
> If but our watchful eyes
> Can trace it 'midst familiar things,
> And through their lowly guise."

I should be pleased, later on, if desired, to give a lecture and demonstration to photographers, free, if it could be arranged by appointment perhaps, at my own address—a certain number at a time—and point out what, to an untrained eye, would pass unobserved and lost to the unlearned.

> "'Twas in that glance that God threw o'er
> The young created earth,
> When he pronounced it 'very good,'
> The beautiful bad birth."

I am, yours, &c., JOHN BOOL.

86, *Warwick-street, Belgravia, S.W., August* 5, 1896.

RE POISONS ACT.

To the EDITORS.

GENTLEMEN,—In your Answers to Correspondents column of last week I met with a most remarkable statement under the above heading.

After pointing out to a provincial photographic dealer that it would be illegal for him to sell solutions of bichloride of mercury or cyanide of potassium, you go aside to make an unworthy attack on the Pharmaceutical Society, and make statements which it would be only merciful to stigmatise as ignorance were it not for their obviously spiteful nature.

It is untrue to assert that the Pharmaceutical Society is a trades union. It has none of the attributes of a trades union. It has certain well-defined duties placed upon it by the State; and these duties are, primarily, to protect the public, not to secure the pecuniary benefit of its members.

The penalty, forsooth! It may be news to you to know that the Pharmaceutical Society is compelled by the nature of its Charter to prosecute for all infringements of the Poisons Act, and that these prosecutions annually result in a money loss to the Society.

Your last statement is enough to make a horse laugh. To assert that members of the Pharmaceutical Society, as a rule, know nothing of the uses or properties of cyanide of potassium and bichloride of mercury is so monstrously false that I am surprised you should thus seek to impose on the credulity of the readers of THE BRITISH JOURNAL OF PHOTOGRAPHY, and it assumes great gullibility on the part of your subscribers when such statements are made.

I defy you to produce any facts that will support your statement that any member of the Pharmaceutical Society has been guilty of such gross ignorance as imputed in your columns.

Trusting you will reconsider your perfectly unjustifiable remarks,—I am, yours, &c., WILLIAM HAMPSON, *Pharmaceutical Chemist, Member of the Pharmaceutical Society.*

Leigh, Lancashire, August 3, 1896.

[With regard to the concluding paragraphs of our correspondent's letter, the ignorance imputed was, of course, as to the photographic properties of the poisons named. Were it worth while, we might adduce many amusing instances of pharmaceutical chemists' mistaken ideas as to the uses of photographic chemicals. In reference to the other portions of our correspondent's letter, we see no reason to deviate from opinions frequently given in these pages, and even so lately as last week (p. 500).—EDS.]

THE EXPANSION OF PAPER.

[Autotype Notes.]

EXPERIMENTS, detailed in THE BRITISH JOURNAL OF PHOTOGRAPHY a few years ago, showed that the normal expansion of Rives paper was, in the direction of the web, but the eighth of an inch in twenty-four inches; while that across it expanded more than half an inch. Now, taking the greatest expansion, it will be seen that, after all, it does not amount to much, only about one in forty-eight. That being the case, it is very unlikely that any marked difference would be noticed in, say, the features of a couple of cabinet portraits if they were made on paper cut the two directions from the sheet, though it is manifest that they are different. There is often, however, a much greater difference in some prints than can well be accounted for by the normal expansion of the paper, and the object of this article is to point out the cause.

Paper, when thoroughly soaked with water, can be stretched very considerably, and it is to stretching in the mounting that considerable distortion and dissimilarity—when it exists—in prints is generally due. Quoting from the experiments just referred to, we find that twenty-four inch strips cut longitudinally of the web when mounted wet on stout cardboard (with stretching) measured twenty-four and a half inches when dry. Those cut the reverse way, and similarly dealt with, measured twenty-five and three-quarter inches, or an extension of an inch and three-quarters. That was with plain Rives paper, but on the experiments being repeated with albumenised paper the distension was still greater, namely two inches in the twenty-four, or just one-twelfth. Now, it will be seen that there would be a palpable difference, supposing two prints were made from the same negatives, the one on paper cut along the web and mounted without stretching, and the other cut across it and stretched to its maximum in the mounting. The one would be a twelfth longer than the other, equivalent to a quarter of an inch in a three-inch head.

It is not at all an uncommon thing with some mounters, when a print is not evenly placed on the mount in the first instance, to gently strain it into position instead of taking it quite off the mount again. It will be seen that, in this way, the perpendiculars of a building may be rendered anything but straight, and also that the features in a portrait can be much distorted, particularly by diagonal stretching.

What takes place with ordinary papers also takes place with "parchment paper," and in greater degree even. It is this kind of paper which is used in a collotype process that has been demonstrated frequently before photographic societies during the last three or four years. As, in this method, the paper has to be strained very tightly to keep it flat in the apparatus for inking, it will be seen that collotypes made by this system may show a considerable degree of distortion, and also not be true to scale, unless allowance be made for the stretching in taking the negative.

The expansion of paper may, however, sometimes be turned to profitable account. It may be made the means of producing a more flattering portrait, say, for example, a round face may be lengthened by cutting the paper crosswise of the web, and gently stretching the print in the mounting; or a long and thin face may be similarly broadened. In copying designs to scale, it may sometimes be turned to account in the event of the negative not being strictly to the dimensions ordered, a trifle smaller, for example. If the print be mounted wet, it will be more or less larger than the negative, according to the way of the paper. If, on the other hand, it be mounted dry, and with a mountant that contains a large proportion of spirit in place of water, it will be practically the same size as the negative, supposing the paper be cut lengthwise.

E. W. FOXLEE.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED :—

Harry Lothian, 144 and 146, Freeman-street, Grimsby.—*Two photographs of August Bank Holiday at Cleethorpes.*

Peter Charleton, Garrison Studio, Newbridge, co. Kildare, Ireland.—*Photograph of drum horse, Jack, Royal Dragoons, with camp for background. Photograph of drum horse, Mick, 14th King's Hussars, with camp for background.*

G. B. Bradshaw, High Bank, Altrincham, Cheshire.—*Photograph of Rev. F. Wainwright, Vicar of St. John's Church, Altrincham (cabinet size). Photograph of Rev. F. Wainwright, Vicar of St. John's Church, Altrincham, and Mrs. Wainwright (cabinet size).*

RECEIVED.—C. L. Hett ; thanks.

R. W. WILLMOTT.—Quite unable to publish your letter.

EXCHANGES.—L. R. ; C. S. E. ; F. M. G. We have abolished them.

PHOSPHORESCENT SULPHIDE OF CALCIUM.—PHOSPHO. The substance is supplied, we believe, by Horne, Cow Cross-street, E.C.

PHOTOPHIL.—I. If a silver print, treat it with a solution of bichloride of mercury, and then, to restore it, use sodium sulphite. 2. Scarcely worth while.

MIRROR.—PROCESS. Ordinary plate glass, however thick, will not do for a reversing mirror. The glass for the purpose must be optically worked, so as to secure a perfectly plane surface.

INK STAIN ON A PHOTOGRAPH.—HANNIBAL. This may be partially, if not entirely, removed by the application of hydrochloric acid. But you run some risk of damaging the photograph if a silver print.

COMPETITIONS.—HERBERT MITCHELL writes : "Will you kindly tell me if there are any photographic competitions taking place at any time in connexion with your paper ?"—In reply : We do not hold competitions.

HALATION.—HALO asks if halation can be prevented by backing plates with collodion ?—In reply : Of course not ; but, if with the collodion any dark red or brown pigment is mixed, an effective remedy will have been devised.

LENS.—SYMMETRY. You are probably alluding (although it is merely a surmise on our part) to the Stigmatic lens. This is the invention of Mr. H. L. Aldis, and is manufactured by Messrs. Dallmeyer, Newman-street, W.

PHOTO-CHROMOSCOPIC CAMERAS.—ANXIOUS wishes to know if the cameras referred to by Mr. Ives and Mr. Edwards, in their correspondence in the JOURNAL some months ago, are yet on the market.—In reply : We are without tidings of such cameras.

COPYRIGHT IN MUSIC.—S. G. If there is a permit on the music that it may be sung in public without fee, that does not entitle any one to reproduce it as a lantern slide, to be thrown upon a screen, and used at evening entertainments in rural districts.

REPLYING TO CORRESPONDENCE.—W. R. We do not undertake to reply to letters through the post. This also answers several other correspondents who have neglected to peruse the directions printed at the head of our Answers to Correspondents column every week.

DEVELOPING CHLORIDE PRINTS.—A. C. COOKE. Prints on the paper named can be developed, after being partially printed ; but, whether that method of proceedure is largely practised by professional photographers or not, we are scarcely in a position to say.

LIVER OF SULPHUR.—C. B. Sulphide of potassium, or, as it is often termed, "liver of sulphur," may be made by fusing together one part of sulphur and four parts of carbonate of potash. When cold, the mass must be broken up and kept in a wide-mouthed, corked bottle.

VARNISH.—H. MEYER. If you refer to the ALMANAC, you will find several formulæ for negative varnishes, all of which are good. We cannot, however, say if the commercial varnish mentioned is made by any one of them. English manufacturers, like those of your country, do not publish the formulæ by which they manufacture the materials they sell.

PATENT.—T. C. B. We can scarcely advise you in the matter of taking out a patent for your invention. The chief points for your consideration are : Is the invention new and original ? Doubtless it is as regards yourself, but that is not sufficient to make a valid patent if the thing has been done, or substantially done, before. Also, if you are able to establish a valid patent, will you be able to turn it to commercial advantage ? If you cannot, it will be quite useless to waste money in taking out a patent.

MOUNTING PRINTS IN OPTICAL CONTACT WITH GLASS.—J. R. S. wishes to know how this is done.—In reply : Apply a warm fifty-grain solution of gelatine to the face of the print, and immediately lay it face down on the glass ; then apply a squeegee to ensure contact and freedom from air bubbles.

MAGIC PHOTOGRAPHS.—REV. T—— L—— asks what these are.—In reply : They are ordinary silver prints, fixed without being toned. They are well washed, and placed in a solution of mercuric chloride, which obliterates the picture. They are again washed, and, when it is desired to make the pictures visible again, a solution of sodium hyposulphite will do the needful.

ARTICLED PUPIL.—TRUSTEE. There are no fixed or recognised terms for "articled pupils" or apprentices in the photographic profession ; so much depends upon the status of the firm, and what they are capable of teaching. We may, however, say that, if we were in your position, we certainly would not pay half the premium you mention to "article" your charge to the firm named, or, indeed, any sum whatever.

CHLORIDE PAPER.—E. HARRISON (Burton-on-Trent). The reason the sample of chloride paper enclosed is not so good as that you "buy at the shop" is that you have not prepared it in the same way as the commercial papers are. We should recommend you to purchase the paper ready for use, unless your consumption of it is such as to warrant you in laying down proper plant for preparing it as the commercial papers are prepared.

COPYRIGHT.—IGNORAMUS says : "Please will you answer the following questions ? 1 have got a *carte-de-visite* to copy cabinet size, and it has printed 'copyright reserved' on the mount. The person was an ordinary sitter to the photographer who made the print. 1, Is it copyright ? and, 2, Would I run any risk if I made the prints wanted ? The print is a good age, is yellow, and slightly faded."—In reply : 1. Probably the photograph is copyright. 2. Most likely.

COPYRIGHT.—R. BIGGS. If the sitter came and sat to you in the ordinary course of business, your competitor cannot be restrained from making enlarged copies of the portrait and selling them. You have no copyright in the portrait, therefore what would be the use of registering it ? The Office makes no inquiry as to the legality of the copyright when they accept the registration. If the one who registers it has no right to it, of course the registration gives him no legal right to it.

COPYING.—W. A. DEL MAR. It is impossible to answer such a question. How is it possible to say the exposure necessary to make a copy with no other data as to light than the "middle of August and stop *f*·32 ?" The only practical advice we can give is to make a trial negative at the time and thus judge for yourself. This can be done on a small plate on a portion of the subject, if the copy is to be of large size. A single experiment of this kind will teach more than anything we can say.

DEVELOPMENT.—S. COOPER. As the developer you have used is one that the makers of the plates say is not to be recommended for that class of work, we do not see how we can help you, except by telling you to employ those they say are best suited for the tones you desire. Makers know, or at least ought to know, the developers best suited to their plates to produce the various colours they are capable of yielding, and we should say that they had best be adhered to in ordinary practice.

SPOTTING.—A. VANDYKE. "Can you tell me of any method of spotting albumenised prints before enamelling so that the spotting does not come off in the process ?"—If the prints are spotted with the ordinary oil colours, as sold in tubes, thinned with spirit of turpentine, the spotting will not be disturbed by the enamelling. Special colours are, however, sold for the purpose. They may be obtained from Mr. Rudowsky, Guildhall-chambers, E.C., and of most of the large dealers.

TONING.—H. MASON. Your second letter does not help at all. "Sensitised paper" does not tell us how the paper is salted and sensitised, and what proportion of chloride to silver it contains. If you cannot get the grey tones you desire with the acetate bath, try the lime toning bath or the carbonate of soda bath. Possibly the negatives you are using are such as will not give fine grey tones. As much depends upon the negatives, as regards tones in the prints, as upon the paper or the toning bath.

FIXING.—A WORTHING AMATEUR writes : "How many prints, 4¼×3¼, will three ounces of hyposulphite of soda fix ? I fear I have been using much more than has been necessary, and thus adding to my photograph icontlay ?"—This is a difficult question to answer, because it entirely depends upon the chloride of silver in the prints that has to be removed, and every brand of paper, whether albumen, gelatine, or collodion, varies in the quantity of chloride it contains. Practical photographers, as a rule, do not stint the hypo, but use enough to ensure the perfect solution of the silver salts, because the hyposulphite of soda is so very cheap.

THE BERGHEIM-DALLMEYER LENS.—JOHN says : "I shall be obliged if you will inform me whether you consider a Bergheim-Dallmeyer soft-focus portrait lens suitable for amateur portrait photography. My camera (Optimus) is whole-plate (extension, sixteen inches). Should I purchase a lens of the ordinary size for whole-plate, or would it be better to have the next size larger ? Also, is the Bergheim-Dallmeyer soft-focus lens a rapid one ? I much like the soft effect it produces. I have a good studio."—In reply : 1. The lens is, we believe, suitable for the work. 2. The firm recommend their No. 2 for this size and upwards. 3. Not so rapid as the ordinary portrait lens, but quick enough, we think, for your requirements.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1894. Vol. XLIII.—AUGUST 21, 1896.

Contents.

EX CATHEDRÂ.

Mr. A. W. Rider, who has been associated with the Eastman Photographic Materials Company from its formation, eleven years ago, and has acted as Secretary since its conversion into a limited liability Company, informs us that his connexion with the Company has been severed. He proposes shortly engaging in the photographic business on his own account, and we are sure he will carry with him, in his venture, the good wishes of his friends in the photographic world.

* * *

The judgment of Mr. Justice Romer, in the case of Shew *versus* The Société des Lunetiers, which is given in another part of the Journal, establishes the validity of the patent for the well-known "Eclipse" camera, and the shutter working between the lenses. The patent for the camera was taken out in the year 1885—when there were few if any hand cameras on the market—so that it was not until over ten years afterwards that Messrs. Shew were compelled to defend their position. It says a great deal for the practical value of a hand camera that, after the lapse of so many years, during which innumerable new forms have been introduced, it should be worth risking a costly lawsuit in defence of the patent granted for it.

* * *

We hinted last week at some of the fiascos that have attended the comparatively frequent "invention" of photography in natural colours, and, as the subject is of constant interest, it may be useful if we allude to two or three processes that have been introduced in recent years, only to be either ridiculed out of existence or neglected as impracticable. It may be said, with reference to the main subject, that, so far, what is known as the three-colour system and the interferential method of Lippmann, both of which have been frequently described in our pages, are probably the only processes that have yielded results at all entitled to the designation of photography in natural colours, and that inspire any hope for the ultimate practicability of colour photography.

* * *

Shortly after the publication of Lippmann's process, in 1891, Dr. Kopp, of Lucerne, momentarily startled the world by claiming to have made the discovery of photography in natural colours. His process—which appears to have died with him (for the inventor went over to the majority shortly afterwards)—seems to have been a modification of one attributed to Poitevin. Briefly described, it consisted of exposing specially prepared silver chloride paper to diffused light, with the formation of silver subchloride. The paper was then immersed in a mixture of potassium bichromate, copper sulphate, and mercurous nitrate and zinc chloride. Exposure of such a paper was said to produce the yellow and green colours, the other colours being "veiled." However, by varnishing the green and yellow, the other colours could be developed with sulphuric acid, all the colours, "including white" (as Dr. Kopp averred), appearing in "all their brilliancy." We cite this process (of which the barest outline only has been given) as typical of many, based on early experiments, which resulted in comparatively small success, the main difficulty being to fix or retain the colours when obtained.

* * *

At the instance of a once well-known West-end photographer, whose invention the "process" was said to be, much stir was made in the non-photographic press and elsewhere, about nine years ago, over his alleged solution of the problem of taking photographs in the colours of nature. Upon examination the

results appeared to be simply albumen prints coloured with liquid pigments and varnished. It was also surmised that the process was really a modified crystoleum one, the pigments being applied behind a pellicular positive, and backed up by paper. The "discovery," as our readers will have imagined, came to nought. Some light was thrown on the nature of the inventor's views on the production of photographs in colours by his subsequent claim to have reproduced Daguerreotypes in natural colours by a process of applying the "colours of the vibrations" stored up in the originals for thirty years!

* * *

THE method of colouring photographs just described has formed the basis of many subsequent discoveries! of photography in natural colours, as a study of our patent intelligence even so recently as the last two or three years will show. Indeed, it was not for the want of effort that a company was not formed a comparatively short while ago, for the purpose of licensing out such a process! Lastly, it will probably be within the recollection of many of our readers that an analogous or so-called process of photography in natural colours figured in the criminal courts a few years ago, and that one of those who took a prominent part in the exploitation of the discovery received a term of imprisonment. Having regard to the fact that in about thirty years there has been discovered but *one* method of taking photographs in natural colours—Lippmann's—which has been verified by independent experimentalists (Messrs. Lumière, to wit), and that even this process does not appear to be within measurable distance of coming into use, we think we have said sufficient to justify an attitude of scepticism when any fresh announcement of the great discovery is made.

* * *

DURING Li Hung Chang's brief sojourn at Hawarden on Saturday afternoon, Mr. G. Watmough Webster, of Chester, was fortunate in being able to secure several admirable photographs of Li seated in company with Mr. Gladstone. Several interior and exterior views of the Castle and the assembled company were also obtained. The picture of the Chinese Envoy and Mr. Gladstone will appear in several of this week's illustrated papers. We may be permitted to cite, for the benefit of others, Mr. Webster's business alertness in disposing of the photographs, for the negatives were developed and retouched, gelatino-chloride prints struck with all dispatch, and the finished photographs personally submitted and disposed of to the editors of the illustrated press before noon on Monday last.

THE FIXING POWER OF HYPO.

THE recent investigations of Messrs. Haddon and Grundy on the subject of the fixing and washing of prints, and the discussion of the matter that arose on the latter gentleman's paper at the Convention, have deservedly brought this important question once more to the front. But, while recognising to the full the absolute necessity for perfect fixation and thorough washing, it seems to us there is a tendency in some directions, by ultra-carefulness, to nullify much of the benefit that is likely to accrue from giving the subject its due amount of attention.

A question answered in the Correspondence column of our last issue is only a type of a very large number that are constantly reaching us, as to the precise fixing value of hyposulphite of soda. "How many prints, $4\frac{1}{4} \times 3\frac{1}{4}$, will three ounces of hyposulphite of soda fix?" asks our correspondent, and adds, "I fear I have been using much more than is necessary, and thus adding to my photographic outlay." From other similar communications we judge that a large number of our readers are under the impression that, as Mr. Haddon's experiments show that we have been in the habit of submitting our prints to an unnecessarily long washing after fixing, so perhaps we may be overdoing the fixing operation itself. Hence a tendency to cut down expenses by economising hypo, and by attempting to reduce the fixing of prints to an exact process, like emulsion-making.

But we would point out that the success, or otherwise, of the fixing and washing process does not depend upon the chemical side of the question at all; that is simple and straightforward enough, and, if the reaction between the fixing agent and the silver salts were the only condition to be studied, there would be no such thing as fading. If, in fact, as some seem to imagine, it were simply a question of using so much hypo for so many prints, to ensure perfect fixation, all the difficulties that have surrounded silver printing from its earliest days would at once disappear. But such is not the case, for the difficulties, where they exist, come entirely from the mechanical side, and lie in the uniform and free application of the fixing agent to a mass of prints in such a manner that the necessary chemical changes shall be thoroughly and efficiently carried out; and, after that, in an equally thorough washing to remove the products of the reaction. There is no chemical difficulty, but simply a mechanical one; but, in proportion as we attempt to reduce the process to a strictly chemical one, so do we create chemical difficulties from the increasing inefficiency of the mechanical treatment.

Let us try and illustrate this. In the process of fixing, that is to say, in the course of the solution of the unreduced chloride of silver by the hypo, a chemical change goes on which results in the formation of a double salt—a hyposulphite of soda and silver—together with chloride of sodium. But, as is well known, there are two of these double hyposulphites, one of which is perfectly soluble, the other insoluble, or but partly soluble and easily decomposed. In the formation of the first-named, which is the ultimate object of *perfect* fixation, three parts of hypo combine with two parts of chloride of silver. Thus:—

$$3Na_2S_2O_3 + 2AgCl = Ag_2Na_43(S_2O_3) + 2NaCl$$

and the result is a perfectly soluble salt, which is easily washed out of the prints. But, when the quantity of hypo present is insufficient to form the completely soluble salt, the reaction is slightly different, and the two substances combine in equal proportions—

$$Na_2S_2O_3 + AgCl = AgNaS_2O_3 + NaCl$$

forming the insoluble double salt, which is the chief cause of fading.

Looking at the above formulæ, it is, of course, the easiest thing in the world to calculate exactly how much hypo is necessary to fix a given number of prints, if we possess the other necessary data to work upon. According to the figures given above, three ounces of hypo, supposing it to be *pure*, should dissolve a little over an ounce of chloride of silver. We say "supposing it to be pure," because the ordinary hypo of commerce, or, at least, as supplied to photographers, is certainly not an article above suspicion, and, if its impurities consist of nothing worse than water, its fixing value must b

materially lessened thereby. However, we have volumetrically tested a fairly good commercial sample, as supplied for photographic purposes; and as the mean of three estimations, all pretty close, the actual fixing value was less than one per cent. below the theoretical or calculated.

But of what practical value is this information when obtained? We may know the power of our fixing bath, and the quantity of silver chloride it is capable of dissolving; but how are we to arrive at the quantity to be dissolved? Even if the paper-makers gave us an exact analysis of the composition of these films, and a guarantee that they contained the quantity of AgCl stipulated, how are we to estimate what proportion of the original salt remains unreduced, and therefore subject to solution? The thing becomes an absurdity at once.

Even supposing this difficulty were removed, and it were possible to accurately adjust the proportion of hypo requisite to the formation of the soluble double salt, the use of a fixing solution containing just the theoretical quantity would be absolutely impracticable owing to the impossibility of evenly distributing and so as to act uniformly over the whole surface of the prints, and also because, as the solution became gradually exhausted, the last portions of the hypo would cease to have any power of action and the process would never be completed. In fact, the efficiency of the fixing operation depends wholly upon its being carried out in the presence of a considerable excess of hypo.

The necessity for this excess appears in another way. In fixing a large batch of prints it is practically impossible to keep them separate during the whole process, and the action of the hypo must consequently take place during the interval of turning them over. If a very weak solution be used, then all fixing action ceases as soon as the print is shut off by contact with another, and the chloride of silver consequently, unless the process is very prolonged, partially escapes conversion, or is only reduced to the form of the insoluble double salt. If a stronger solution, and plenty of it, be used, the excess of hypo confined between the prints keeps up the fixing action even whilst they are in contact, and so ensures perfect or complete reduction of the chloride.

Of course it might be possible, in operating upon a single print, or only a few, to successfully work with a quantity of hypo somewhat approaching the theoretical quantity, though we much doubt it. But it would be at the expense of a far greater amount of applied trouble and far longer time than would in any way compensate for the saving in hypo a hundred times over. Our fixing salt is cheap enough to permit of its generous use when the advantage of that course is so plain, and we think it will be agreed that any attempt at economy in the direction indicated by our correspondent of last week is in the highest degree foolish.

Besides, turning again to Mr. Haddon's paper, in order to derive the benefit of the short washing shown to be possible and effective, we must just have perfect fixation, that is to say, the thorough conversion of the chloride of silver into the soluble form. When this occurs, the double salt diffuses freely out of the gelatine film without any risk of decomposition; but, when the conversion is imperfect, or barely sufficient, and where there is not an excess of hypo present, some of the silver is pretty certain to be left behind in the insoluble condition—not as chloride, but as hyposulphite. The former would discolour by exposure to light; the latter does not, but gradually undergoes a change, in the course of which yellow sulphide of silver is formed which constitutes the so-called fading.

The imperfect fixation charged against the sulphocyanides, when introduced some years ago, arises from a different cause, namely, the precipitation of the chloride as either chloride or sulphocyanide on dilution of the solution. So far as we can ascertain, this never occurs in the case of hypo, as a solution of any given strength saturated with AgCl may be diluted without causing any precipitate.

Pure Ether.—This liquid, which, once upon a time, was the subject of poignant discussion as to its exact condition when pure, is now rarely referred to since the decline of collodion. Still, it will be interesting to learn, on the authority of Herr H. Thorns, that ether, even when most carefully purified, is not the neutrally reacting substance so often imagined, for it turns sensitive red litmus paper blue.

Röntgen Ray Investigations.—From practical and from theoretical standpoints investigations continue to be made to the continued elucidation of some aspects and the further confusing of others. With regard to the wave-length, Dr. Fomm, of Munich, has made a series of investigations which result in his evaluating them at about one-fifteenth the length of the smallest hitherto calculated wave in the ultra-violet.

Their Reflection and Transmission.—This has been investigated by M. F. V. Dwellshauvers Dery, and he finds no regular geometric reflection, though, from certain of his experiments, a diffuse reflection seemed to be indicated. He placed a plate face downwards, and half covered it with ruby paper, and sheets of brass, copper, tin, and collodion were placed under this, then followed a second plate, film upwards. It was found that the collodion increased the transmission, and that in practice exposure was diminished by covering the film with a sheet of collodion. The metals reflected in the following order: tin, zinc, copper, brass, iron, platinum, gold, lead, aluminium. The most important fact was the ruby paper intercepted a large proportion of the reflected rays, which, the writer pointed out, could not, in consequence, be Röntgen rays proper.

The Fluorescent Tablets.—Herr W. Arnold has been experimenting in various directions, and his experience was that tungstate of lime was the most luminous of all salts under the action of the rays—more marked, indeed, than the platino-cyanide of barium. Other writers obtain somewhat similar results, though it is evident that considerable variations in the fluorescent power are to be observed, according to the mode of manufacture. Messrs. Hopkins & Williams in this country, for example, supply a tungstate for Röntgen work at about four times the price of their ordinary tungstate.

Interesting Photographs.—A few weeks ago, it will be remembered, we mentioned that Li Hung Chang and that veteran statesman, Prince Bismark, were photographed together in a group at the latter's residence at Friedriehsruh. The group has since appeared in one or more of our illustrated papers. On Saturday last, as remarked elsewhere, Li paid a visit to Mr. Gladstone at Hawarden, and during the stay these two veteran statesmen were also photographed together, as a group, sitting side by side. No doubt, these two pictures will serve as a pleasing reminder of his European visit to the Celestial "lion" on his return home.

The Late Solar Eclipse.—After all the well-considered preparations made for it, and the flocking thither by scientists, *dilettanti* and otherwise, the Norway Eclipse Expeditions may be considered a failure in every way. Evidently the Norwegian clerk

of the weather was not propitious on the occasion, as he has not been, according to all accounts, the greater part of this season to tourists. The pleasure-seekers accompanying the expedition excursion did not, we are informed, derive all the enjoyment they anticipated from the trip on account of the weather. It is easy to be wise after the event, and some are now saying that the locality chosen for the observations was ill-advised. Anyhow, the weather does not seem to be much better anywhere else where observers went. A recent Japanese telegram says that the eclipse was clearly seen at Tokio and at Yokohama; but, in the north, where the astronomers had gone, the weather was wet and cloudy all the time, so that no observations, photographic or otherwise, could be made.

Sir John Millais.—Within the space of a few months the Royal Academy has lost its President for the second time by the death of Sir John Millais, who passed away on Thursday, last week, at the age of sixty-seven. Sir John, we are told, was by no means anti-photographic, and often used photographs to help him in his work, particularly in the case of portraiture. This may in some measure be due to the pronounced pre-Raphaelite tendency of the artist in his earlier life. Amongst the most popular subject works of Millais may be mentioned *The Huguenot*, *Concealed Royalist*, *My First Sermon*, *Apple Blossoms*, *New-laid Eggs*, *North-west Passage*, &c. The best known of Sir John Millais' works by the general public is, however, the one that has adorned the hoardings for some years past—we allude to *Bubbles*. This picture was purchased at a very high price—ten thousand pounds it was said—by an enterprising firm, who use reproductions of it as an advertisement for soap.

Failure of Another Arctic Expedition.—Dr. Nansen and Lieutenant Schott-Hansen have arrived home, having failed to reach the Pole, though they got farther north than any previous expeditions, and have beaten the record by four degrees. They had, however, to "rough" it to an unpleasant degree, until they quite accidentally fell in with Mr. Jackson, of the Jackson-Harmsworth Expedition. With misleading maps, stopped chronometers, and travelling on foot for weeks, the situation, for a time, must have been anything but pleasant.

We have more than once commented on the fact that in all Polar expeditions—as, indeed, now with all expeditions—photography is an important item, but we seldom see or hear anything of the results. It is therefore interesting to learn, from a communication from Mr. Jackson, that something has been done in that direction. Here is a passage: "During the lulls in the gales, and when the sun occasionally shone, we were able to take a large number of valuable photographs, which will give you an excellent idea of the terrible Arctic nature of this ice-capped country." These will, indeed, be an interesting collection.

Protecting Negatives.—At the last meeting of the North Middlesex Photographic Society one of the members mentioned that, another member had told him of a dodge for obviating stains on an unvarnished negative, which consisted of interposing a sheet of papier minéral between the negative and paper while printing. He also mentioned that he found that no loss of definition resulted therefrom. This may be a good way of protecting this film, but many people, no doubt, have wondered why varnishing the film did not suggest itself as the best way of avoiding stains. It is astonishing the number of amateurs, and professionals too for that matter, who complain of stained negatives, from printing, yet how few take the little trouble of varnishing them with the view to their preservation till too late. In this way very many valuable, and irreparable, negatives have been utterly ruined. There is no better way of preserving gelatine negatives that have to be much printed from than that suggested by the late Mr. Wm. Bedford, which is this: Thoroughly fix and well wash the negative; then, when dry, coat with enamelling collodion, and afterwards varnish with a good spirit varnish.

A Note on Thermometers.—Under this heading there is, in the current number of the *Chemical News*, a note by Dr. Phipson on a topic we have more than once dealt with; that is, the incorrect reading of many thermometers whose indications are relied on for accurate work. He points out that though the ordinary laboratory thermometers may be supplied by first-class makers, and be "guaranteed," various discrepant records suggest that the instruments are in fault, and he, himself, having had many thermometers brought to him for testing, has found them wrong by 4° or 5° F., and sometimes even more. For ordinary photographic purposes minute accuracy is not a cardinal necessity, but when the manufacture of pyroxyline, for instance, is involved, a difference of a degree or two of temperature will cause a considerable variation in the quality of the resulting product. Dr. Phipson, however, strangely enough, does not call attention to the simplest method of ascertaining the correctness of a thermometer, that is, to send it to Kew, where, for a sum varying from one shilling, upwards, according to the range of the instrument, it will be tested and a record of its performance given down to one-fifth of a degree F.

The Balloon Expedition to the Pole.—There seems to be, according to recent telegrams, some doubts as to whether Herr Andrée's balloon expedition to the Pole, in which photography is to be a not unimportant feature, is on its way, whether it is in abeyance, or whether it will be abandoned until next year. In due course we have been told that the balloon house has been completed, and everything was ready for inflating the balloon ready for ascent when the wind was in a favourable direction; then that the balloon was inflated, but four rents were discovered in it, and these might cause such a delay that the balloon would have to be left in the balloon house till next year. This, however, has since been questioned by the wife of the maker of the balloon, who says that, if a few weak points were discovered, her husband has with him everything to make them good. One weak place is more than enough in a balloon, particularly in such a perilous voyage as that proposed. Up to the time of writing, the latest news was to the effect that, on the 9th inst., a vessel, thirty miles south of Spitzbergen, encountered a southerly wind, and that its captain believes that Herr Andrée may have started on his journey.

A New Electric Gas Lighter.—The ever-lighted gas burners, as those know only too well who have had them long in use, are so liable to get out of order that the introduction of a simple and automatically lighted burner will be welcomed, for the use of such appliances in the dark room alone is simply invaluable. We have pleasure therefore in calling attention to the "New Era" gas lighter, made by the American Electric Company, Boston, Mass. This new burner is operated only by a key, which is securely attached to the valve, the latter extending up through the body and terminating in the pillar containing a lava tip. The spring electrode is rigidly secured to the pillar, and turns with it when the key is operated. A pin enters this spring electrode and projects a little below it, resting upon and sliding over the surface of a cam. This cam is so constructed that, as the key is turned from left to right, the pin is gradually elevated by the cam, and lifts the point of the spring electrode until it is brought in contact with the point on the fixed electrode. It then falls off from this high position, the contact is broken, the spark is made, and the gas is let on and lighted. In turning the key to the left to extinguish the gas, the pin slides on a lower plane of the cam, which permits the spring electrode to pass under the fixed electrode without contact, after which it reaches an incline, which eventually restores it to its former position.

The Use of Aluminium.—There is at the present time so much capital sunk in concerns established for the manufacture of this metal that it cannot be wondered at that every effort is made to exploit its use in further directions. That its production pays well is shown by the balance-sheet of the Aluminium Company, which enabled a dividend of fifteen per cent. to be declared a fortnight ago. Sir Henry Roscoe presided at the meeting, and he

nticipated still better things in the near future, though he pointed out that the Company's patents for the production of sodium—an important factor in the manufacture—were being infringed in Germany. When the "new metal," as it was called when a cheap way of making it was first discovered—now over a quarter of a century ago—it was called silver white, untarnishable, unchangeable in the air, and so on, and it was largely used for jewellery, and other ornamental purposes. This use soon fell off, for it was quickly found that too much was claimed for it, and that, like nickel, it quickly lost its silvery whiteness, and became more like lead, and often spotty-looking. It is true it can be lacquered, but lacquer will wear off, and then the metal tarnishes. Further, the new, bright metal soils the hands and clothes. Still, when all these objections are urged and proved, the fact of its light weight remains, and it is on this account most valuable for many purposes. Lens mounts, camera fittings, and tripods will continue to be made of aluminium, so long as the owner of such apparatus is aware that nothing unusual has happened, if they become discoloured, no real harm is done.

JOTTINGS.

Bicycles, metaphorically speaking, are in the air. It seems to be the prayer of many people that they were literally so, or, at any rate, that they might be anywhere but on *terra firma*: for the bicycle, if what one hears be true, is responsible for the complete dislocation of several branches of trade, whose representatives therefore regard the wheel fever that is sweeping over civilisation with distinctly unfriendly feelings. The Revenue and Board of Trade returns point to a condition of general prosperity, but many minor industries are crying out against the badness of the times, and they ascribe the depression to the spread of cycling. Oddly enough, the carriage builders do not appear to have been adversely affected by the rivalry of the omnipresent safety; and so far I have not heard mention of a slump in horse flesh. To labour the subject in these columns is obviously unnecessary, and I should not have mentioned it but for the fact that some photographic manufacturers and dealers are joining in the chorus of envious lamentation to which I have referred.

It is possible that some of the fringe of amateur photographers—the butterflies—have, this season, dropped camera work for cycling but I find it hard to believe the attractions of photography to be so slender, or the interest taken in it so small, that any considerable number of persons who have once taken it up will be permanently weaned from it. Experience tends to show that it is all the other way. This year, everything has favoured the cycling boom: "Society" has affixed its hall mark to the wheel; the fair sex, sheep-like as usual, has followed its leaders; the weather has been superb, and trade has revived. Probably next year the boom will still be expanding; but, even then, I do not think that photography will suffer any more than (if it has at all) this year. Cycling and photography do not clash, so far as I can see; neither do they parallelise. Their relations to each other are of an entirely independent nature. *En parenthèse*, it is satisfactory to note that professional photographers appear to have no cause to regret the growth of cycling.

I am aware that many will regard my opinion that cycling and photography have little in common as very heterodox. The two things, I admit, go admirably together—on paper. It is twenty years since I first got astride of a wooden velocipede, and getting on for that time when, in company with another aspiring youth, I first attempted wet-collodion portraiture in a back garden, with very remarkable results. On and off I have been a cyclist and photographer ever since; but, as a cyclist, I have never felt the smallest inclination to carry a camera, while, as a photographer, I have never been tempted to adopt the wheel as an adjunct to photography. I believe my case to be that of many thousands of others. That cyclists *do* take photographs, and that photographers *are* sometimes also cyclists, cannot be denied, but it does not prove the existence of a link between the two pursuits. It is a good many years since articles on cycling and photography began to appear in these pages, and just as long since the old Temple Bicycle Club used to have occasional entertainments, with cyclo-photographs thrown in; but the alliance between cycling and photography is no nearer now than then. In the old ordinary days the cycling journals occasionally had "photographic" departments, which attracted no more attention than they do now, or than a "wheel" column does in a photographic paper. There is just as much reason for journalists making a feature of cyclo-photography as there is for booming photo-cricket, photo-rowing, photo-football, photo-tennis, or photo-tipcat. The expressive if inelegant locution that "there's nothing in it" hits off the worthlessness of the idea to a nicety.

Mr. T. A. Scotton, of 11, Pear Tree-road, Derby, who was included in the various Presidential groups taken at St. Mary's Abbey, York, during Convention week, asks me to state that he would be pleased to receive copies of those groups. On my own responsibility I will add that, doubtless, Mr. Scotton will send exchange prints, which are sure to be good, as he is an able photographer. So far, I have not seen many Convention results, although the opportunities for serious photography, as I have already pointed out, were exceptionally good.

Mention of the Leeds Convention suggests a brief reference to the Convention of the Photographers' Association of America that met in June last at Lake Chautauqua, and full reports of which have just reached this country. Professional photographers from all parts of the States appeared to have been present; a competitive exhibition of photographs was held; papers were read and discussed; excursions made; receptions and a ball also figured on the programme, and there was a plenitude of Convention incidents and humour such as are not wholly foreign to a similar gathering annually held on this side of the Atlantic. But, of the two, the American Convention, judged by the reports, seems to have been by far the more boisterous. On one evening there was a competition among the photographers for the production of the most catchy and amusing "yell!" Boston led off with:—

"Boston, Boston, here we are
All together, rah, rah, rah!
Are we in it, we should smile
We've been in it all the while.
Si—boom—ah!"

I select this as the tamest of many competitive efforts.

The "demonstrator" is a potent force in photography on the other side and at the Convention "Charlie" This and "Tom" That, representing gelatino-chloride paper firms, &c., were fêted right royally in return, one may surmise, for considerable freehandedness in advertising their wares among the photographers present. We read that there was a well-beaten path from Camp Aristo (the Aristotype Company's representatives appear to have camped out) to the hotel, which suggests various reflections. The papers were not too technical or exacting—"How to Treat a Customer" being the curiously chosen title of one—and a very enjoyable time seems to have been experienced. The personal comments made on the events of the week by some of the American photographic papers would scarcely be considered in good taste here.

The *Kodak News*, published by the Eastman Photographic Materials Co., always contains, in addition to many well-reproduced illustrations, some useful practical notes. The little publication does credit to those responsible for its production. I observe in the last number an article telling how two pocket Kodaks placed side by side may be used to take stereoscopic photographs. May I point out that a *single* camera, used in the hand, may also be employed for taking binocular pictures? All that is necessary to do is, when one exposure has been made, to remain quite still, keep the camera perfectly level, and just move it three or four inches to the left or the right, as the case may be, before making the second exposure. The two negatives so obtained will, with the usual treatment, yield

a proper stereoscopic effect. Of course, it is assumed that, if there are any figures in the view, they have not moved between the successive exposures.

Some thin-skinned chemists apparently do not like the Pharmaceutical Society being dubbed a trade union, which it unquestionably is, as I remarked a year ago, just as much as is the Amalgamated Society of Carpenters and Joiners, which, like the Pharmaceutical, exists solely for the aggrandisement of its own members. All the talk about the Pharmaceutical Society "protecting the public" against photographic dealers selling a few pennyworths of mercuric chloride is silly nonsense. Assuredly the public *does* want protection, but it is against the chemists, for taking upon themselves to prescribe for all sorts of ailments, thus encroaching upon the preserves of qualified medical men. It is not a little singular that, after having half ruined the photographic-dealing trade by mercilessly cutting the prices all round, the chemists heap insult on injury by neglecting no opportunity of persecuting the dealer with that model of privileged inquity, the Poisons Act, the schedule of which is a disgrace to the legislature. As to that trade union, the Pharmaceutical Society, I recommend its defenders to read the remarks of the Edinburgh Judges and press on its action last year in prosecuting two Edinburgh dealers for calling themselves "photographic chemists." They should have been sufficient to make any self-respecting Society petition to have its charter revoked.

COSMOS.

PHOTOGRAPHIC CHEMICALS AND THEIR ADULTERATIONS.

WITHOUT some knowledge of the chief adulterations ordinarily to be met with in the photographic chemicals of commerce, and of the tests whereby these adulterations may be detected, the technical equipment of the practical photographer, however perfect it may be in other respects, cannot be regarded as complete.

When we take into consideration the extreme delicacy of the beautiful series of reactions upon which photography is based, we shall, I think, be ready to admit that the absence or presence of impurities in our chemicals may have a larger share of influence on the quality of the results than we have hitherto suspected. Many of the defects which we are wont to attribute to other and quite different causes would probably, on investigation, be found easily traceable to the unsuspected door of the manufacturing chemist, and, the real culprit once identified, the growth of the mighty army of anxious inquirers and puzzled editors would no longer increase by leaps and bounds.

After all, the photographer has the remedy—to a large extent at least—in his own hands. A very slight familiarity with the processes of elementary analytical chemistry will enable him to distinguish between good chemicals and bad, a measure of knowledge amply fulfilling all his requirements.

For convenience' sake, adulterations may be broadly divided into two great classes, the active and the passive.

This division is not arbitrary, but essential, and is accordingly of more than merely theoretical importance.

By active adulterations are to be understood all such impurities as are possessed of properties actually injurious to any process or product into which they may find their way. By passive adulterations, on the other hand, are comprehended those adulterating bodies whose presence is without influence on the reactions into which they may be introduced, except, indeed, in so far as it weakens the active properties of the ingredients in which they exist as contaminations.

Now, if we are careful to observe the distinction between these two classes of bodies, it will greatly facilitate our analytical operations; because, having once, by simple testing, identified an impurity of the first or active class, we are spared the trouble of estimating its actual proportions, and for this very obvious reason, that any body which is *per se* of a harmful character ought to be rigidly excluded, whether its actual percentage be large or small.

The only remedy under the circumstances is to substitute a good article for a bad, and, fortunately for the photographer, this can generally be easily done.

A different course may, however, be pursued in the case of the other or harmless class of adulterations. With regard to these, seeing that their influence wholly depends not on their quality, but on their proportions, the processes of quantative analysis may often be employed with advantage. Once the percentage of the adulterating bodies has been ascertained, due allowance can, of course, be made for any action which, indirectly, they are likely to exert in that particular branch of work in which the crude chemical finds its proper application.

On this account I have not hesitated to introduce to the photographer's notice several processes pertaining to quantitstive analysis. These, however, are mostly of a simple character, my object here, as elsewhere, having been to restrict myself to the description of such tests as do not make too serious a demand on the knowledge and skill of the operator, or require, as a condition of success, the elaborate and complicated adjuncts of the chemical laboratory.

I propose, in the first place, to treat of the adulterations of the principal metallic salts employed in photography; after this, the adulterations of certain of the acids and alkalies will claim their share of attention; and, finally, I shall have to speak of the impurities of one or two miscellaneous compounds not referable to any single distinct head.

I.—POTASSIUM SALTS.

Bicarbonate of Potash.—The formula of this salt is $KHCO_3$. The pure crystallised bicarbonate should contain forty-seven per cent. of potash. The commercial bicarbonate frequently contains a percentage of neutral carbonate, together with moisture, insoluble earthy matter, and traces of potassium sulphate and chloride.

Neutral potassium carbonate, if present, may be detected by the orange red precipitate which is produced in a solution of the sample on the addition of a few drops of a strong solution of mercuric chloride. The superfluous moisture may be estimated by drying a weighed portion of the sample in a watch glass over sulphuric acid under a desiccator, and noting the loss of weight from time to time, as long as any change is apparent. The moisture cannot be determined by heating, as the salt is thereby decomposed into carbonic acid, water, and neutral carbonate. The silica and insoluble matter may be estimated by collecting them on a weighed filter, which, after washing and drying, being reweighed, will, by its increase of weight, afford the data for calculating their percentage. Potassium sulphate may be detected by dissolving forty or fifty grains of the sample in dilute hydrochloric acid, and then adding a strong solution of barium chloride, which will produce a white precipitate if any sulphate be present. If no sulphate be present, potassium chloride may, in its turn, be identified by dissolving the bicarbonate in dilute nitric acid, and treating the concentrated liquor with solution of nitrate of silver, whereby any chloride will be precipitated in the form of chloride of silver.

Independently of these tests, the general purity of a sample of bicarbonate may be very readily ascertained by means of the following simple volumetric process. A standard solution of pure oxalic acid is prepared by dissolving 6·3 grains of the crystallised acid in an ounce of distilled water. This solution should be effected in an alkalimeter tube or burette of 1000 fluid grains' capacity. When the acid has been dissolved, water must be added until the bulk of the whole is exactly 1000 grain measures. Oxalic acid being bivalent, and 6·3 grains being one-twentieth of its molecular weight, the whole volume of the solution is therefore equivalent to one-tenth of the molecular weight of the bicarbonate of potash, which tenth amounts to exactly 10·01 grains. Ten grains of the sample should be dissolved in half a pint of water contained in a white porcelain basin. The liquid having been coloured a deep blue by means of a few drops of solution of litmus (or cochineal extract, in which case the colour will be violet), the oxalic acid solution is then added gradually from the alkalimeter, and the addition is continued until the last trace of violet is replaced by a vivid pink, indicating the completion of the reaction. Should the sample be pure, this stage will not be reached until the whole contents of the alkalimeter have been exhausted. Should it, as is suspected, be adulterated, the extent of the adulteration may be estimated from the volume of oxalic acid consumed in the process.

Supposing that 900 measures have been consumed, we know that, as every hundred measures are equivalent to one grain of pure bicarbonate, ten grains of our sample must contain nine grains, or ninety per cent., of bicarbonate, and one grain, or ten per cent., of foreign matter.

Potassium Bichromate.—This salt is often contaminated with sulphate of potash. Sometimes, too, it contains traces of alkaline carbonates. Sulphate of potash in a sample may be detected by adding to the aqueous solution, previously strongly acidified with hydrochloric acid, a few drops of a weak solution of barium chloride.

Any sulphate present is precipitated as barium sulphate. Carbonates, if present in quantity, may be identified by the effervescence which ensues when the dry sample is treated with dilute hydrochloric or sulphuric acid. The powdered sample should be wholly

soluble in water. When dried in a water bath, it should not appreciably lose in weight, seeing that the pure crystallised bichromate is an anhydrous salt.

Potassium Bromide.—This salt occasionally contains traces of potassium carbonate or hydrate. Instead of testing for these separately, it is more convenient that the percentage of bromide in a weighed portion of the sample be alone determined. This may be done as follows: Dissolve 8·5 grains of pure crystallised nitrate of silver in 1000 grain measures of distilled water. Each 100 measures of this solution are equivalent to ·595 grain of potassium bromide. Dissolve five grains of the sample to be tested in a pint of distilled water, transfer to a porcelain basin, and add a small crystal of potassium chromate. The yellow liquid is then titrated with the nitrate solution, the latter being added from a burette or alkalimeter tube. When the yellow colour is changed to an orange-brown, and when, at the same time, the red precipitate of chromate of silver no longer dissolves freely, the reaction is completed. From the number of grain measures consumed, the percentage of bromide may then be calculated. If the sample be free from adulteration, 840·3 measures will have been required.

Carbonate of Potash.—The anhydrous neutral carbonate is that usually employed in photographic processes. The crystallised salt contains two molecules of water. The former is frequently very impure, the principal impurities being those referred to in speaking of the bicarbonate of potash. They may be detected by the tests already mentioned. The carbonate being exceedingly deliquescent, the determination of the percentage of moisture in a sample should never be omitted. It may be estimated by the loss suffered when the sample is heated to low redness in a porcelain crucible.

Potassium Cyanide.—The commercial cyanide is a very crude salt, and frequently contains less than thirty per cent. of the pure cyanide. Among the impurities the following are of most frequent occurrence:—Carbonate of potash, cyanate of potash, potassium ferrocyanide, potassium sulphide, potassium sulphocyanide, and alkaline chlorides and sulphates. The carbonate of potash may be dissolved out by digesting the sample with alcohol of ·853 specific gravity. The residue, dissolved in water and treated with barium chloride solution, will, on boiling, give a white precipitate of barium carbonate if cyanate of potash be present. If a white precipitate of barium sulphate be produced before the solution is boiled, it must be filtered off, and the test repeated on the filtrate. Potassium ferrocyanide may be detected by the blue precipitate which is produced when the acidified aqueous solution of the contaminated sample is treated with a solution of ferric chloride. If potassium sulphide be present, it may be identified by the brown precipitate which appears when the solution is treated with acetate of lead.

Strongly acidified with hydrochloric acid, in which ferric chloride has been dissolved, the solution turns red when potassium sulphocyanide is present. Sulphates may be detected in the sample by treating the aqueous solution with barium chloride, and boiling the precipitate so produced with excess of dilute hydrochloric acid, in order to dissolve out the barium carbonate. The residue will be barium sulphate. Most of these impurities are of the harmless class. Samples, however, which contain more than a trace of potassium sulphide are unsuitable for photographic purposes, and should be rejected. The same may perhaps be said of those containing sulphocyanide. Under ordinary circumstances, it will generally be found sufficient merely to estimate the percentage of cyanide present in the sample. This may be done volumetrically, a standard solution of nitrate of silver, of the same strength as that required in the analysis of potassium bromide being required. Each 100-grain measures of the solution are equivalent to ·27 grain of hydrocyanic acid, and, consequently, to ·46 grain of pure potassium cyanide. Five grains of the powdered sample are transferred to a porcelain basin, and dissolved in ten fluid ounces of water. The silver solution is to be added from the alkalimeter until the liquid begins to be turbid from the formation of a faint precipitate. The alkalimeter is then allowed to drain, and the number of measures consumed is read off on the scale. From this number the percentage of cyanide present is then calculated.

Potassium Ferrocyanide.—The crystallised salt is in general sufficiently pure for the purposes of photography. When purchased in the powdered state, it should be tested for carbonate of potash. This may be done by dissolving it in water, and treating it with a strong solution of calcium chloride. Any carbonate present will be precipitated as calcium carbonate. The sample should be perfectly soluble in water. Any insoluble residue (consisting of the oxide or sulphide of iron) may be removed by filtration.

Potassium Iodide.—The commercial salt frequently contains carbonate of potash, and also potassium iodate, sulphate, and chloride. The presence of the first may be detected by the effervescence which ensues when the powdered sample is moistened with dilute hydrochloric acid. The salt may be purified from carbonate and iodate by digesting it in hot strong alcohol, when these adulterations, being practically insoluble, will be left behind, and may be removed by filtration.

Potassium sulphate may, as usual, be detected by the addition of barium chloride to the aqueous solution, previously strongly acidified with hydrochloric acid to prevent precipitation of any carbonate present. Potassium chloride, if present, will be precipitated along with the iodide on adding a few drops of solution of nitrate of silver. On treating the washed precipitate with ammonia, the chloride of silver only is dissolved, and, after separation from the residue of yellow iodide, may be reprecipitated by the addition of a little weak nitric acid to the ammoniacal solution. The percentage of iodide in a commercial sample may be estimated volumetrically. For this purpose, 8·3 grains of mercuric chloride must be dissolved in 1000 grain measures of water. Take twenty grains of the sample, dissolve in water in a basin, and, having filled an alkalimeter with the chloride solution, add the latter gradually, stirring the contents of the basin continually during the titration. Continue the addition until the red precipitate of mercuric iodide is no longer dissolved. The number of degrees consumed, multiplied by 1·3083, will give the percentage of potassium iodide in the sample.

Potassium Oxalate ($K_2C_2O_4 \cdot 2H_2O$).—The commercial salt frequently contains carbonate of potash. When crude oxalic acid has been employed in its preparation, it may also contain traces of insoluble organic matter. To detect the former, treat the aqueous solution with solution of calcium chloride. The mixed precipitate of calcium oxalate and carbonate thereby obtained, treated with hydrochloric acid, dissolves with effervescence, due to be liberation of carbon dioxide. If, however, the precipitate consist only of calcium oxalate, no effervescence will result. Any insoluble matter which the sample contains may be separated from the solution by filtration in the ordinary manner.

Potassio-aluminium Sulphate.—This salt, the common potash alum of commerce, is often contaminated with potassium chloride, sulphate, and chloride of iron, and insoluble siliceous matter. In testing for chlorides, the aqueous solution of the sample must be treated with acetate of lead. Any chlorides present will be precipitated in the form of chloride of lead. If salts of iron be present, a reddish-brown precipitate will be produced when caustic potash is added in excess to a boiling solution of the sample. Another portion of the solution may be boiled with dilute nitric acid, and tested with ferrocyanide of potassium. A blue precipitate will indicate iron. Samples of alum which contain more than a mere trace of ferrous and ferric salts should not be employed by the photographer, on account of the appreciable influence which these salts exert upon the compounds of silver. Any silica and insoluble earthy matter present as contaminating bodies may be removed by filtration.

The various salts of potassium of which I have been treating include all those which are required in the ordinary processes of photography. In my next paper I shall deal with the salts of sodium and ammonium and their adulterations, after which, if space suffices, I shall have something to say concerning the salts of the heavy metals.

MATTHEW WILSON.

CALOTYPES.

Now that photography reaches each year a higher and higher place among handicrafts, and the number of people interested in it directly or indirectly becomes larger as time rolls on, an increasing interest manifests itself in the memorials and relics of the earlier stages of its career. The earliest, or one of the earliest, of the practical processes was the calotype, the invention of Talbot, after whom it was frequently styled Talbotype; and of this beautiful process there are many specimens extant.

The Royal Photographic Society, of late years, has been forming a collection of these calotypes in its museum, and those who are interested in the results obtained by their forerunners in the "forties" cannot do better than examine the many specimens in the Society's collection. First in importance, as being the actual hand work of the inventor are a number of paper negatives of streets in Frankfurt-on-the-Main, and other apparently German towns, views on the Rhine, &c. These were taken in or about the year 1843, and have written on them, by Talbot himself, some of the particulars as to their production, such as: "Frankfort. Gloomy with rain, forty minutes." Most of these have the skies blocked out with Indian ink, while a print which accompanies them shows no signs of fading.

The first book to be illustrated by photographic means, as is well known, was the *The Pencil of Nature*. In the Society's copy of this important book, which was formerly the property of the late J. Traill Taylor, is the following inscription in that gentleman's writing: "*Talbot's Pencil of Nature, The Earliest Work on Photography.* The negatives were taken (on paper) anterior to 1843. The prints are on plain paper, anterior to the discovery of gold toning. The fading of some is caused by the paste around the margins." "The Earliest Work on Photography" should obviously read *by* photography, since Daguerre's own book had run through two editions in this country in a translated form, and had been followed by several others of like nature. Speaking of this work of Daguerre's, it may not be generally known that the manuscript of it was offered for sale in this country a year or two ago, when the writer had an opportunity of examining it. It was in an excellent state of preservation, but the bulk was in the handwriting of an amanuensis although some of the corrections, if not all, appeared to be in the author's own writing.

But to return to our subject. *The Pencil of Nature* appeared in six parts, issued by Longmans at irregular intervals, the first being sold at 12*s.*, part two at a guinea, and the rest at 7*s.* 6*d.* each; the first part appeared in 1844, and the last in 1846. The title-page, which is printed in two colours, red and black, in addition to the publisher's name and date, contains merely the words, *The Pencil of Nature*, by H. Fox Talbot, Esq., F.R.S., &c., and the motto, "Juvat ire jugis qua nulla priorum castaliam molli devertitur orbita clivo." The introductory remarks, which occupy three pages, are followed by a brief historical sketch of the invention, narrating how the first suggestion of fixing the image of the camera obscura occurred to Talbot while sketching on the shores of Lake Como with the aid of Wollaston's camera lucida. The plates, which are twenty-four in number, measure $8 \times 6\frac{1}{4}$ inches, the dimensions of the mount being 12×9 inches. No. 3 has for its subject some china, and the letterpress contains the earliest allusion of which I am aware to the use of the stop in a photographic lens. Of this Talbot says, "The glass should be diminished by placing a screen or diaphragm before it, having a circular hole through which alone the rays of light may pass. When the eye of the instrument is made to look at objects through this contracted aperture, the resulting image is much more sharp and correct. But it takes a longer time to impress itself upon the paper, because, in proportion as the aperture is contracted, fewer rays enter the instrument from the surrounding objects, and, consequently, fewer fall upon each part of the paper." Later on, Talbot complains that the green rays act very feebly upon the paper, and hence render it difficult to photograph buildings of a very light colour at the same time as trees, &c., while with plate seven, the leaf of a plant, further particulars as to the effect of different-coloured rays upon the paper are given, and the experiment suggested of filling a room with the invisible rays at the violet end of the spectrum in which objects might be photographed, although persons in the room would remain invisible to one another.

Plate XII. represents the bridge of Orleans, and will be subsequently referred to; while Plate XIV. represents a group of three men with a ladder, and is an early example of portraiture by the calotype process. *Apropos* of Plate XV., Talbot states that his country home, Lacock Abbey, Wilts, was the first building "ever yet known to have drawn its own picture. It was in the summer of 1835 that these curious self-representations were first obtained. Their size was very small; indeed, they were but miniatures, though very distinct, and the shortest time of making them was nine or ten minutes."

But enough has been said of this interesting work, which has been described at greater or less length many times before, and with the remark that the fading which has taken place is mainly at the edges, the centre of each print being of a deep red colour, which was presumably its tint when first prepared, we will leave the *Pencil of Nature*.

In the year 1845, that is between the publication of the first and last parts of the *Pencil of Nature*, a book called *Sun Pictures in Scotland* was produced by Talbot. Most of the prints are similar to size and preservation to those in the more important work; but the last ten of the twenty-three prints it contains are about $4 \times 3\frac{1}{4}$ inches only, and are mounted two on a page. It is doubtful whether this book was ever offered for sale: no publisher's name appears, the title-page merely bearing the name of the book and author, the same motto as in the *Pencil of Nature*, and the inscription, "London, 1845," but copies of it seem fairly numerous. The Royal Photographic Society acquired theirs some three years ago, and since that date the writer has had another through his hands. The letterpress which helped to make the *Pencil* interesting is here absent, the only information given, beyond the titles of the various pictures, being a printed slip with the following words:—"*Notice to the Reader.*—The plates of the present work are impressed by the agency of light alone, without any aid whatever from the artist's pencil. They are the sun pictures themselves, and not, as some persons have imagined, engravings in imitation."

In addition to the foregoing, there is in the Society's collection a fine album, very recently acquired, containing eighty-two calotypes, which are, generally speaking, in much better preservation than the foregoing. This is undoubtedly due to the mountant, which in this case must have been less conducive to fading, and has been applied all over the prints. It contains in MS. a list of the subjects, and an inscription to the effect that they were taken in 1843 and are among the earliest examples of photography. Whether they were all taken in 1843, or whether some of them must be referred to a later date, seems doubtful, as well as the original owner of the work. In all probability this was, however, Talbot himself, since many of the subjects are those in the *Pencil of Nature* and in *Sun Pictures in Scotland*, which are known to be his work, and they are, moreover, better prints than those in the published books; in fact, one or two of the prints in this book would hold their own easily with those produced to-day in every respect. Notably is this the case with an old arched doorway, which is a fine print without any traces of fading whatever. The additional subjects in this book are chiefly views in Oxford, Cambridge, Dublin, Kenilworth, Rome, and Malta, and it is safe to say that it represents in itself alone the finest collection of calotypes got together prior to the year 1847.

In the year 1846 the *Art Union*, a periodical afterwards known as the *Art Journal*, published a lengthy account of the "Talbotype sun pictures," and gave as an illustrated supplement to this a print from one of Talbot's negatives which had been used in the production of the *Pencil of Nature*. Different copies of the paper got different subjects, the Society's copy containing a print of the "Bridge of Orleans," already referred to. It is attached to a sheet of paper, the size of the periodical, by its edges, and, as in the case of the print in the *Pencil*, is very much faded—so much so, in fact, that little beyond the heaviest shadows are to be seen. The other copies of the periodical which the writer has at different times seen have all been faded in an equal degree. An adhesive label under the print informs the reader that it was taken from nature in 1843.

With this copy of the *Art Union* was issued a circular, a copy of which Mr. T. Bolas recently presented to the Society, which states that it is intended to send "well-qualified persons to visit America, the Indies, and other distant lands, and to bring home from thence authentic views of the natural scenery of those regions," and which refers once more to the belief that these early calotypes were not actual sun pictures, but engravings or lithographies (*sic*) made from the original image obtained by light. The terms for licences to work are stated as being, for amateurs, one guinea; for business purposes, "according to circumstances."

Hitherto the calotypes mentioned have been mainly the production of Fox Talbot himself, but in the next volume to be mentioned this is no longer the case. *Calotypes by David Octavius Hill, R.S.A., and Robert Adamson. Edinburgh MDCCCXLIII. to MDCCCXLVIII.*, is in every sense of the word a magnificent work. Its pages, over a hundred in number, are 25×18 inches in measurement, and are handsomely bound with gilt edges, the whole book weighing many pounds avoirdupois. The promise of such an exterior is not disappointed on opening the volume, except, perhaps, as regards the dimensions of the photographs themselves, which are never more than about whole-plate size, and seem lost on such large mounts. They are, generally speaking, in good preservation—in some cases, in conspicuously better preservation than their mounts, which are dotted here and there with mildew—and bear out an observation based on other specimens that, broadly speaking, calotypes which have been mounted by the edges only have faded; those which have had the mountant applied all over their backs have remained very much as they originally appeared. This fading, although commencing at the edges with an irregular termination towards the centre of the print, suggests at first sight that it is the nature of the mountant itself which has given rise to the fading, and this is, no doubt, what has usually occurred, although it frequently happens that the fading so started has taken place also over the unmounted parts as well.

Artistically, those best qualified to speak pronounce the joint productions of D. O. Hill and Robert Adamson as of great value. Mr. Maskell—surely no mean authority on such matters—coming across some of Hill's work some year or so ago, pronounced him to be a "man of the very earliest days of photography whose work would appeal, both in portraiture and in landscape, to the most advanced supporters of 'the new movement'" which in photography

it will be seen dates from 1843). Mr. Maskell is so far almost the only photographer we know who has drawn attention to the work of Hill, and who has attempted to give him the place he undoubtedly deserves in artistic photography; but, in so doing, he seems to minimise the part played in these joint productions by Robert Adamson (whom he calls John Adamson) on the ground, apparently, that he was a "distinguished chemist." Chemist or no chemist, he and Hill between them are to be thanked for the production of a series of photographs which are not only highly meritorious in themselves, but which are in many cases portraits of celebrities of a most valuable character, and portraits which should be copied by some more permanent methods without loss of time. Amongst others, Lady Eastlake, Dr. Chalmers, Professor Fraser, Sir John Steele, R.S.A., Wm. Etty, R.A., Sir W. Allan, and James Ballantine are portrayed in the volume in the possession of the Royal Photographic Society, together with a number of subjects, such as "Newhaven Fish Wives," "Soldiers at Edinburgh Castle," &c.

In addition to the foregoing, the Society's collection contains a number of calotype negatives by Corelli Bere, and some prints by the process of scenes in the neighbourhood of the Crimea by Mr. Maynard. They are being added to from time to time as occasion offers, and already occupy the most prominent place in the museum which the Society is gradually acquiring. R. Child Bayley.

BY-PATHS OF EXPERIMENTAL PHOTOGRAPHY.

(President's Address to the Hackney Photographic Society.)

It has seemed to me that the circumstances and the occasion of this address warrant its being cast in a comprehensive rather than in a particularised form. My predecessor, Mr. E. J. Wall, supplies me with a precedent for this course; for, if I remember aright, he devoted his inaugural address to an examination of the advantages of specialistic photography, enumerating the various branches of work that may be taken up, and recommending the individual photographer to select one of those branches and acquire a mastery of it, in preference to dabbling in several. Society activity is about to recommence, and indoor work will again receive more attention than it has received during the past three or four months, so that the opportunity is, possibly, a favourable one for an address of this nature, which, if it possesses, in some persons' estimation, the disadvantage of being technical and not artistic, may, I hope, balance that defect by the quality of being intelligible.

The Encouragement of Photographic Research.

In a paper that was recently read before one of the societies it was sought to ascertain in what manner, and by what means, photographic societies could benefit photographic art. Opinion has also been expressed that photographers in conclave do not give much attention to art subjects; and some photographic extremists even appear to think that discussions on technical matters are entirely superfluous. I can well sympathise with the section of photographers that laments the neglect to which art is subjected by photographic societies, for, paradoxical as it may sound, I entertain the converse feeling that photographic societies do not by any means attempt or achieve enough for technical photography. It is quite true that facilities for the reading of papers, and the holding of discussions thereon, are abundant; but the ultimate benefit to photographic progress would probably be greater were original experimental work and research singled out for encouragement by the hundreds of photographic societies in the United Kingdom.

That the need for some such extraneous encouragement has been observed and felt is evident from the action of the Photographic Convention of the United Kingdom, which has set aside a portion of its capital and income for the institution of a fund to be applied in aid of research. It is permissible to hope that occasion may shortly arise for the expenditure of some of this money. In the mean while, it is of interest to note that independent photographic investigation reposes in the hands of but very few men. To mention Dr. Hurter and Mr. Driffield, Captain Abney, Mr. Bothamley, Mr. Haddon, and Mr. F. B. Grundy, is to name probably all those who have recently undertaken independent and original experimental work of the first class. The number appears extremely small, but it must be remembered that such investigations as these men take in hand demand an amount of time and an extent of knowledge and application such as few persons possess, or, if they possessed it, would care to expend gratuitously. It is no secret that Messrs. Hurter & Driffield's work in the determination of the speed of plates extended over a period of several years; that Mr. Bothamley has been following up the action of colour-correct sensitisers for a very long period; and that the beautiful experiments in ascertaining the extent to which silver prints really need be washed after fixation, which look so simple on paper, cost Mr. Haddon months of time and work.

Wanted—A Substitute for Hypo.

With the suggestion that photographic societies might well co-operate in a concerted effort to provide the means for the greater encouragement of photographic research, I may next be allowed to point out that there still remains a wide field open for investigation work of a minor nature, which either individual photographers or societies might undertake at comparatively little cost of time or money. Take, for example, the question that has from time to time cropped up as to the replacement of hyposulphite of soda by a less troublesome but equally efficient fixative for negatives and prints. You are, doubtless, aware that the silver salts are more or less soluble in the alkaline chlorides and bromides, in the sulphocyanides, in sodium sulphite, and in ammonia. In the very early days the first-named were used for prints, but did not answer satisfactorily, as they were said to be not perfect solvents. Potassium bromide was used with more success, although its action was slow, and the addition of strong ammonia to the hypo bath has been, and is, occasionally recommended to facilitate fixation. Sodium sulphite has been found to be a too weak solvent. The drawback to the employment of potassium cyanide for negatives and prints is that, being a fairly powerful solvent of metallic silver, it must be used weak and carefully, otherwise your half-tones are likely to suffer; but the sulphocyanides have been used as fixing agents, though they are somewhat inferior in power to hypo for the purpose. The greater solubility of silver chloride in these and other reagents suggests that, for paper prints, it might be possible more readily to displace hypo for fixing prints than for negatives. Probably the sulphocyanides, according to the stated solubility of the silver haloids in them, give most hope of success for the double purpose; but the entire subject is one that awaits exhaustive experiment, and is well worth taking up when we consider that, notwithstanding its excellence as a solvent, hypo has many well-known drawbacks, of which few of us are without experience. I suggest the subject as being well within the reach of individual experiment, as the work required is obviously not of a very complex character.

Orthochromatics

The very interesting subject of orthochromatic photography demands in its higher branches—such as the effect and action of various dyes on gelatino-bromide of silver, and the determination of the spectrum sensitiveness of the preparation—an amount of care and close attention that the ordinary member of a photographic society is, as a rule, unable to bestow upon it; but there is one division of the matter that has recently come into prominence in which many are well qualified by time and endowment to take part. I allude to the alleged orthochromatic properties of sensitive plates not specially corrected for colour. You are aware that it is held by many that by the use of suitably selected coloured screens an ordinary plate may be made to yield an orthochromatic effect, but that the practicability of such a result is denied by others. Such a point as this—which appears to conflict with the theory generally held with regard to orthochromatic photography, viz., that the use of a coloured screen on a non-colour corrected plate merely increases the exposure without imparting to the plate sensitiveness to the less refrangible spectrum rays, is one well within the power of a fairly skilled worker to refute or confirm. On the other hand, the theory I have referred to frequently receives, in the experience of all of us, a very rude shock, for, no matter what colour of glass or fabric we use in our dark-room lamps, are we not always careful to keep the light as much as possible from our plates, and do we not often find that some amount of exposure to that light produces fog? I myself have found this to be the case even with glass that has been guaranteed to cut out the actinic rays, and the experience is one that seems to contradict the theory of the non-sensitiveness of ordinary plates to yellow and red. But the conditions governing the reproduction of objects in colour-correct values not only deserve more study than they receive, but it is quite certain that colour-sensitive plates are not used so much as they ought to be. This is more especially apparent with the growth in use of half-tone blocks. These always strike me as having a tendency to degrade the colour values of the originals, which might frequently be obviated by the employment of colour-sensitive plates in the taking of the negatives.

Developers, &c.

There is, again, the apparently simple but really complex question of development. This, it is true, receives a vast deal of attention at photographic society meetings, which, however, is seldom of a nature to make any reliable addition to our knowledge. For what are known as the newer developing agents, all sorts of advantages and properties have been claimed that have been admitted by some, and denied by others, on far from complete evidence. It is really a difficult matter to convince most old workers that for negative work pyro ammonia and pyro soda, and for bromide paper ferrous oxalate, are excelled by more modern compounds, and this is not surprising when we consider that no attempt has been made to demonstrate by scientific means wherein the practical advantages of the newer reagents are supposed to lie. This is a branch of investigation eminently adapted to be taken in hand by photographic societies, for it would be a simple matter to lay down uniform conditions of working, within the limits of which any photographer of ordinary intelligence could keep himself. It is questionable, however, whether the matter is now really worth taking up until a problem of much greater importance has been solved. I allude to the nature and constitution of the latent or undeveloped image, a subject that appears to have been lost sight of during recent years. It may be fairly conjectured that, when

this fascinating but elusive secret of science has been unlocked, development will enter upon a new phase, and that therefore we are at present dealing with an unknown product, which leaves us very much in the dark as to what development really is—I mean, of course, the precise action that takes place in the reduction of the exposed surface.

In determining the merits and properties of a given printing process, or for making comparisons between various papers, so far as their power of rendering the scale of gradation contained in our negatives is involved, or, indeed, for arriving at the actual scale the paper is capable of depicting, the members of a society, all working under determined equalised conditions, might accomplish some really valuable work. It is matter for surprise that comparative experiments of this kind should be virtually neglected, and mere individual expressions of opinion or solitary experiences relied upon in preference. This suggestion is obviously typical of others in which advantage might be taken of the circumstance that a number of workers, as represented by a photographic society, could avail themselves of the opportunity of studying a subject concurrently, and of subsequently comparing results.

Societies as Agencies for Research.

These illustrations, indicative of the existence of easily traversed bypaths in experimental photography, are merely typical, and might be almost indefinitely increased, but those I have chosen serve, I hope, to prove my point, that there is a wide field open for research work of a minor kind. Nevertheless, I am appealing less to individual photographers than to members of societies collectively to divert a portion of their efforts in this direction. The difficulty of filling a season's programme is one experienced and complained of by nearly all honorary secretaries; but that difficulty, I venture to suggest, arises from the habit they have of too often looking away from home for men and material. Most societies nowadays include within their membership one or two men of more or less chemical and physical knowledge, and few are without several of proved photographic ability. Would it not be possible, then, for these societies, utilising the knowledge possessed by such members, occasionally to depart from the beaten track of set demonstrations, papers, discussions, or lantern evenings, and systematically to undertake and report on the investigation of some of the innumerable little chemical and other problems which modern photography still offers for solution? A great deal of useful knowledge, even of a negative character, might be gained in this way. In their collective capacities, societies hold exhibitions and excursions, and they undertake surveys, the publication of journals, and so forth; so why not a little serious work in the shape of research? Of course, one always thinks the most of one's own ideas, and I fancy I discern in the one I am tendering you the germ of what possibly might prove to be a valuable movement; for assuredly a combination of some 300 societies, all willing to aid in research work, could be made a powerful factor in photographic progress.

It is perhaps of use to remark that one of the drawbacks to individual experiment or research is to be found in the circumstance that confirmation or verification of one's results is not always to be had. This difficulty is one that vanishes in the case of a society possessing several members competent to undertake such work, and is another argument in favour of my suggestion.

Suggested Exhibition of Pure Photography.

All that I have hitherto said is a plea on behalf of constituting photography a craft or science of precision. Photography, as an "art," is already well looked after. We have it on unimpeachable authority that it demands little or no photographic knowledge, and therefore it does not exact precision of aim or application. It demands imagination, and in recent years, at any rate, it has had it to such an extent that humble mortals like myself have occasionally been driven to conclude that the authors of many so-called art photographs have relied too much upon their imaginations, or have exercised them when they are in a condition of disease or decay. It is time, I venture to submit, that the technical photograph had its share of popular attention and applause. We have exhibitions, occasionally of a peripatetic character, devoted to pictorial photography, in which photography, *qua* photography, plays a part of relatively small importance; do you not think, therefore, that an exhibition exclusively devoted to *technical* photographs would come as a welcome change? The Royal Photographic Society might consider the idea; for it is said that during the last four years its annual exhibitions have been so excessively well patronised by "pictorial" photographers—the competition to be hung in Pall Mall has, in fact, been so keen—that for lack of accommodation a number of disappointed would-be exhibitors have been compelled to take refuge elsewhere, and thus in neither place has pure or technical photography received that share of attention which is clearly its due.

Thomas Bedding.

THE REPRODUCTION OF MOVING OBJECTS.

Photography has, during the past year, made many claims on the attention of the public. The truly wonderful results obtainable by Röntgen's method will continue to excite the interest and admiration of those interested in matters scientific, and will find extensive application in surgical circles. To the layman, however, says *Anthony's Bulletin*, perhaps one of the most marvellous outcomes of photographic research and inventive ability is the combination of instruments for reproducing, with practically absolute fidelity, moving objects, and exhibiting them in enlarged form upon a screen, with all distinctness, and with a truth that is amazing. What the phonograph does for the voice, the new apparatus does for objects in motion. With a perfect phonograph and a perfect apparatus, such as we are about to describe, the words and actions of any speaker or number of persons may be recorded and exactly reproduced at any time. The full significance of this it is not easy to recognise to-day; but, as the years roll by, the value of a combination of phonograph and vitascope will be appreciated. Events of to-day will be reproduced for posterity, and our children will marvel at our customs and scoff at our points of weakness. As a means of recording important events, the vitascope stands easily first.

We use the word vitascope without desiring in any way to give offence to the makers of other similar instruments, all of which are excellent in every way. The projecting apparatus is known under the names eidoloscope, vitascope, kineopticon, animatographe, and cinematographe, and in the results, as shown in the theatres and music halls, there is very little to choose between them.

The kinetoscope is, doubtless, familiar to all our readers, and the objections to it are obvious. The small size of the image, the obvious photographic effect, and the fact that only one person can, at a given time, view the travelling band of film, militate against its commercial success. Just as the sounding apparatus has, to a large extent, superseded the ear pieces in the phonograph, so the projecting apparatus has relegated the kinetoscope to comparative obscurity. In the new apparatus the images on the travelling band of film are enlarged to life size and thrown upon a screen, thus affording an opportunity for the effect to be witnessed by a large audience.

The general principle of the method is as follows:—A band of sensitive film, about one and three-quarter inches wide, and some 150 feet long, is, by means of suitable mechanism, exposed upon an object in such a manner that a series of successive exposures are made upon the band of film with a rapidity of from twenty-eight to fifty per second, each negative measuring about seven-eighths of an inch long and three-quarters of an inch wide. This band of film is then developed in large wooden tanks, fixed, washed, and dried, being afterwards run through a machine in contact with a second sensitive strip, upon which a series of positives are made by exposure to an electric light. This positive strip is developed and treated in the usual manner, the result being a succession of small lantern slides. This strip is punctured to fit the driving machinery, and is then run through the projecting apparatus at a very high speed, with the result that the object is reproduced upon the screen, showing the exact motion and expression existent at the time of exposure. The method, then, consists in making a succession of negatives in as short a time as possible, and exhibiting positives made from them in such a manner as to make one succeed the other as rapidly as possible, the impression to the eye being that of continuous motion.

The effects produced are simply wonderful. One very well-conceived and remarkably successful record is that showing a suburbanite watering his garden by the aid of a hose pipe. His mischievous boy steps upon the pipe, thus cutting off the supply of water. The innocent amateur gardener, after puzzling over the cause of the trouble, proceeds to investigate, finally examining the nozzle. The youngster removes his foot, deluging his respected parent, who, after a lively chase around the garden, catches the urchin, and administers chastisement. Shown on the screen, enlarged to life size, it is a truly remarkable series. Every expression of consternation, glee, and disgust, and the various evolutions performed by each from start to finish, are faithfully reproduced, and the audience is aroused to a pitch of enthusiasm never excited at a lantern-slide exhibition, and seldom seen anywhere. Another record is a street scene, with two children dancing to the music from a hand organ. An actual street organ is played behind the curtain, and the whole effect is very real. In some instances the band of positive film is carefully coloured, and here the effect is truly lifelike. When it is remembered that there may be 5000 or 6000 positives to be tinted, it is seen that this colouring is no small undertaking. It is a peculiar fact that scenes from home life take better with the general public than more ambitious efforts. The record showing wash day at home aroused much more enthusiasm than an acrobatic trio or a regiment of soldiers. The projection of these images is not absolutely perfect, but this is due to slight imperfections in apparatus and to other causes, which experience will enable the operators to overcome. The chief trouble seems to be due to a slight vibration, causing a certain amount of blurring. The source of this trouble may be in the taking camera or in the projecting apparatus, or in both. The sprocket wheel, which engages the holes on each side of the band of films, seems to us a source of trouble, for the holes in the film must become elongated, causing the film to slip a little. Again, if the feeding is at all irregular, trouble must ensue. These, however, are little difficulties that mechanical ingenuity will master.

During the past month some trouble has been experienced during the development of these long rolls of film from frilling and reticulation. This has been partly overcome by using cool solutions; but, until the film itself was cooled, some trouble was always experienced. The camera being principally of metal, and being exposed for some considerable time to the

sun's heat, the film becomes quite warm, and the sudden immersion in ice-cold water is liable to prove disastrous. If the film is kept in a cool place for a few hours, developed and fixed in cold solutions, and washed with water that has passed through an ice tub, no trouble will be experienced. The expense attached to the making of a record is not inconsiderable, and in many cases duplication is not possible; every precaution is therefore necessary.

EXPERIMENTAL NOTES.

THE old photographer used so often to fume his paper that it was considered worth while by some commercial houses to place fuming boxes on the market. Now that we no longer sensitise our own paper, but are content to buy P. O. P., fuming is no longer heard of, and probably there are many readers of the JOURNAL who have never fumed a piece of paper in their lives; yet it is, even with gelatine and collodion printing-out papers, a great help sometimes. Not only does fuming the paper make it print quicker, but for matt-surface papers which are destined to be toned with platinum, whether the vehicle be collodion or gelatine, the fuming produces far greater richness and depth in print.

I need hardly say how to fume paper, and the only precaution to be observed is, if gelatino-chloride paper be fumed, the negative must be varnished, or it will beget a goodly crop of silver stains, as the gelatine so readily absorbs the moisture. When exceptionally harsh negatives have to be printed from, there is a somewhat simple means which can be readily used by any one, with which considerable variation in the gradation of the resulting prints can be obtained. This is immersing the paper in a five per cent. solution of sodium phosphate for about one minute, or else passing a flat brush liberally charged with a ten per cent. solution of sodium phosphate over the surface; or more satisfactory even than this is a mixture of sodium phosphate and ammonium carbonate. After drying, the paper is practically about three times as sensitive; and the only difficulty is that it is so sensitive, and may print so flat, as to be practically useless, but this is only intended for very harsh negatives. Paper treated in this way will not keep, but must be used within three days.

If, however, as frequently happens, we have excessively thin flat negatives, such as are too often obtained with a hand camera, it is possible to so treat ordinary P. O. P. as to obtain exceedingly harsh contrasts, and this is by the use of a 2½ per cent. solution of potassium bichromate, and painting the surface of the paper with this. Considerable care has to be exercised in using it or the paper will be abnormally hard, and therefore utterly useless for all but the very weakest ghosts of negatives.

It may possibly not be out of place to point out how very rich deep tones, in fact with deeply printed matt papers, almost black tones, can be obtained by using the sulpho-cyanide bath if prepared in a particular way. Assuming that we wish to use the whole of a tube of gold, dissolve one ounce of potassium sulphocyanide in four ounces of distilled water and heat to 80° C., then dissolve the chloride of gold in four ounces of distilled water and heat to 80° C. and add gradually with constant stirring to the sulphocyanide solution and allow to cool. This, when diluted to the normal strength, will, if the prints are left in it till they appear grey, when examined by a transmitted light, with a faint red tinge in the shadows, be very nearly black on fixing. Bühler adds a quarter of an ounce of strontium chloride to the gold solution, but so far as I can see this has but little, if any, action on the toning powers of the bath.

Messrs. Abney and Lyonel Clark, in their book on "Platinotype," state on p. 64, that the sensitising solutions for platinotype paper will not keep long: "the solution will only keep in hot weather about ten minutes, or in cold weather perhaps twice as long." It would be interesting to learn how this fallacy has arisen. I am now experimenting with a mixture of ferric oxalate and chloro-platinite solution which was mixed fourteen days ago, and it is as good as when first mixed. In the presence of any organic matter, such as may be used for sizing, it will not keep more than about two hours, but the pure chemicals properly prepared *per se* will at least keep fourteen days, in the dark of course, although the bottle has been frequently opened and used from.

Whether anybody now wishes to make ferric oxalate or not, except, possibly, for experimental purposes, I do not know; but, after trying almost every method that has been recommended, I have found Weissenberger's a long way the most satisfactory with a slight alteration, the tip for which was learnt from Hübl. Powder up 52 grammes of ammonia iron alum, and place in a beaker about three inches diameter, ten inches high. Stick a little bit of paper on the outside of the beaker so as to mark the exact height of 85 cm., then place the powdered alum dry into the beaker and add to it with constant stirring 20 cm. of liquor ammoniæ and 10 cm. of water. Stir for five minutes, and then fill up the beaker with distilled water, stir, and allow the precipitate to settle, decant the supernatant liquid, and repeat the operation till there is no longer any smell of ammonia. The precipitate and the water it contains must not finally occupy more space than the 85 cm. mark, then add 21·5 grammes of pure oxalic acid, and stir. The peculiar greenish-yellow solution will readily form, and the total bulk should be made up to 100 cm. This is a capital method for quickly preparing a solution of ferric oxalate, the whole operation only taking about three hours, and, after filtering, it is ready for use.

There is, fortunately for platinotype workers, the satisfactory intensification process of gold, followed by metol, suggested by Dollond; but for those purists who will not admit this as satisfactory, but must deposit platinum on platinum, I can commend the process lately suggested by Hübl, which is simple and very easy of control. Five parts of a ten per cent. solution of sodium formate are mixed with five parts of a two per cent. solution of perchloride of platinum, not the chloro-platinite, and 100 parts of water. In this the image will steadily gain in intensity. This bath may also be used for negative intensification, and also transparency work, but there seems to be some little uncertainty about its action in these cases, probably due to the gelatine.

To those who, like myself, love to dabble in practical chemistry, the formation of barium or potassium platino-cyanide is not a difficult matter. In the first place, a stream of well-washed hydrogen sulphide should be passed through a solution of platinic chloride, heated to 60° C., the precipitated platinum sulphide well washed, and then dissolved in just sufficient warm solution of potassium cyanide, and on evaporating crystals of the platino-cyanide $K_2Pt(CN)_4 3H_2O$ will be obtained—the mother liquor containing equal parts of potassium sulphide and thiocyanate. If, instead of the potassium cyanide, barium cyanide be used, the barium platino-cyanide will be obtained. It is essential that the potassium cyanide be pure, as many commercial samples contain a good deal of sodium cyanide.

Some question has arisen as to the poisonous properties of the thiocyanates, or, as they are usually called, the sulpho cyanates; and in one of the American papers great fun has been made of those who have stated that they are extremely 'poisonous.' Dr. Aarland has experimented, and found that he could take one gramme of ammonium sulphocyanide, usually termed in Germany 'rhodanammonium,' without any ill effects. The question still remains, however, whether one might not have hydrocyanic acid formed in the stomach with large doses.

Some attention has been directed lately by Liesegang in Germany, Haddon and Grundy, and Watkins, in England, as to the composition of the pyro-developed image, and they have satisfactorily proved that a colouring matter—the result of the oxidation of the reducing agent—forms an integral part of the image. To those who, having yellow-stained negatives, wish to get rid of this colour as far as possible, the by no means new idea of converting into a black compound may be recommended; and for this purpose the use of an iron salt will be found satisfactory, as was suggested some years back by B. J. Edwards, who recommended ferrous sulphate for this purpose. Possibly more satisfactory than this is the use of a solution of potassium ferric oxalate, slightly acidified with oxalic acid. The iron salt combines with the yellow oxidation product to practically form a black colouring matter very much akin to the old gall and iron writing ink. AND. LIGAU.

IMPORTANT PATENT CASE: SHEW *VERSUS* SOCIÉTÉ DES LUNETIERS. JUDGMENT.

A PATENT action brought by Perry (J. F. Shew & Co.) against the Société des Lunetiers for infringement of their patent "Eclipse" hand cameras and lenses, well known in photographic circles since their introduction in 1885, was tried before Mr. Justice Romer in July last, when judgment was reserved. Justice Romer, in delivering judgment on Monday, August 10, said:—

This patent has many difficulties in its way, but in my opinion it just manages to overcome them.

It is suggested on behalf of the defendants that the patent is really one of large scope, that it is not for an improvement on previously existing portable cameras for instantaneous work—not for a novel combination—but is for a portable camera for instantaneous work as an instrument previously unknown; I do not think that suggestion can be upheld. The claim in the complete specification as amended is carefully limited, and I ought not to depart from it merely because of the somewhat loose description of the invention at the heading, or of the object of the invention at page 2, lines 6 and 7, of the specification. Moreover, I do not think it was intended by the patentee to make so large a claim as is suggested, for the provisional specification (lines 1, 2, 5) limits the form

of the invented portable camera for instantaneous purposes to one which has no loose parts. In considering the other objections, I must distinguish between the camera and lens. I will deal first with the camera. Its utility is not disputed. Its chief advantages over other previously known cameras of the kind are derived from the use of hinge-bound sides, which, when folded out, form a fixed holding for the camera front, and are so placed as to let the front get into position very speedily, and simply by a spring-like action.

Now, it is said that this spring-like action is not described in the body of the specification. But the specification refers to fig. 3, as showing the framework, and the witnesses are practically agreed that the spring-like action must come from what is clearly shown by that figure. So that, if you make the camera according to the invention as described, you must get the advantage in question, and I do not think that a patentee, who sufficiently shows what his patent instrument is and how it is to be made, is bound, as a matter of law, to specially point out all its advantages, or from what special parts of his instrument they are derived. But the defendant makes a further point. He says, admitting the claim is for he camera as a whole—that is to say, for a combination—yet, as a matter o flaw, when the claim is for a combination, the patentee must point out in his specification exactly what the novelty of the combination is, and claim only for that, and, in support of this, he refers to the case of *Foxwell v. Bostock*. But that case, and the authorities on which it is founded have been since explained by the Courts, and it has been pointed out that they really only amount to this, that, when a claim is made to a general combination is not new, but there is only an improvement in some part, then the patentee must point out and claim for the improvement, and not for the whole combination. If the claim is for a combination and the combination is a novelty (and I think that is the case in the patent before me), then the patentee need not point out how far he claims novelty for particular portions which go to make up the combination, see *Harrison v. Anderston Foundry Company*, 1 Appeal Cases, page 574, and *Proctor v. Bennis*, 36 Chancery Division, page 740.

The next objection taken is this: Advantage is taken of a phrase used by the witness James, and it is said that the amendment of the specification (page 2, line 18), by adding the words "and the action of the sides," has enlarged the claim originally made. But I think James, in his evidence, was really discussing the alleged anticipation called the Poleograph, and its cross-extensions, and that really the amendment has not enlarged or substantially altered the real claim, and I cannot see that this objection is raised by the particulars. The objection therefore fails, and I need not consider whether such an objection, if established, would now be fatal, having regard to what was said in the case of *Moser v. Marsden* in the House of Lords. A minor objection was raised, that the framework of the camera is not in any way held by the tension of the bellows body when extended (Specification, page 2, line 18). But, though the holding may not be very substantial, I think there is some holding, especially if the top did not fit very closely.

It is further said that the patent has been anticipated, but the alleged anticipations, in my opinion, substantially differ from the patentee's invention, and have not its special advantages pointed out above. The Scenograph and Poleograph, for example, and the camera shown in the *Bulletin of the Association Belge de Photographie*, have not the hinge-bound sides or the spring catch, which give those special advantages.

The stereograph in evidence would have been nearer, but that has not been proved to my satisfaction. The camera produced comes from abroad for the purposes of this action, and there is no evidence of that camera itself having been used here before the date of the patent.

The witness Lechertier, who spoke to it, could only say that he had in his shop that kind of camera. He was an artist's colourman, and only sold, as agent for another house, this kind of camera as a small part of his general business, and I do not think his experience in cameras, or attention to his camera branch of business, was such as to enable me to depend on his evidence as to the details of the camera he sold; and in any case, if the cameras he sold were like the exhibit in kind, the defendants have certainly not proved to my satisfaction that they had a spring catch or had hinge-bound sides when placed in position so as to be effectual, or hinge-bound in a true sense, according to the plaintiff's invention.

It only remains for me to consider the question, Whether there was sufficient improvement or novelty in the invention to support the plaintiff's patent, having regard to the then existing knowledge? I think, on the whole, there was, although the invention cannot be regarded as an important one. I think there was an advance and improvement on prior portable instantaneous cameras, which was by no means obvious, and required invention sufficient to support the patent. I have not dealt with all the subetantial objections taken before me with regard to the camera.

I must now consider the claims with regard to the lens, that is to say for the instantaneous shutter operating as described in the specification. The only special objections relied on before me were that the invention had been anticipated, and was not good subject-matter of a patent. In my opinion these objections fail. I think the peculiar arrangement of the spring, and the way in which the shutter was operated on by it was ingenious and novel, and was an advance and improvement on the previously existing knowledge sufficient to support the patent.

With regard to the alleged anticipations, I need only refer to (*a*) the Lens Exhibit W. J. L1 (sometimes referred to as the Lancaster or D lens), and (*b*) the shutter called Andrea's. As to (*a*), I think there are substantial differences between it and the plaintiff's. In (*a*) there is only an indiarubber acting for a spring, and this, being elastic, is not so sure or compact as the plaintiff's spring, and the difference of adjustment is not unimportant; and, moreover, the elastic is not coiled round the body of the lens as the plaintiff's spring is. As to (*b*), what is shown by the description and figure in the article in THE BRITISH JOURNAL OF PHOTOGRAPHY differs in so many ways from the plaintiff's that I need not deal with it in detail. But there is in the article a suggestion to change the string and spring shown in the figure for a true watch spring on the axis. The author, however, has not shown clearly what he means by the suggestion or how to carry it out, and Mr. Lancaster, who gave evidence for the defendants, and was himself an expert on the subject, when asked to show how to work the suggestion out, was obliged to acknowledge that he could not do so. Moreover, the plaintiff's spring is not a mere watch spring, and is coiled round the body of the lens and not round the axis of the revolving diaphragm as suggested by the article in question, and I do not think a person reading the article would naturally be led to the plaintiff's invention. The plaintiff's invention has advantages as to the ease and accuracy with which the exposure to the light is provided for, not possessed by the alleged prior inventions.

I ought, perhaps, to add that, with regard to the lens, the defendants raised a similar objection to that raised by them with regard to the camera, namely, that the patentee was bound to point out in his specification exactly what was new and what was old. But I need not repeat what I have above said as to the camera, and, indeed, with regard to the lens, the patentee does sufficiently point out by his claim that the arrangement of the adjustable spring was regarded as new. I have now dealt with all the substantial objections to the patent taken before me, and, as they fail, and infringement is not really disputed, it follows that the plaintiff is entitled to the usual relief.

Mr. Eve: We ask, my Lord, for a certificate, if your Lordship pleases, as to the validity.

Mr. Justice Romer: Yes.

Mr. Eve: And of proof of the breaches.

Mr. Justice Romer: Yes.

Mr. Eve: And then we ask also for delivery up of the infringing cameras and the shutters, and for the usual inquiry as to damages.

Mr. Justice Romer: Yes, you are entitled to that.

THE PHOTOGRAPHIC CHART OF THE HEAVENS.

WE are indebted to our contemporary, *Nature*, for the following:—

At the fourth meeting of the International Committee of the Carte du Ciel, which took place at the Paris Observatory in May, under the presidency of M. Tisserand, the following members were present: MM. Anguiano, Bailland, Bakhuyzen, Christie, Donner, Duner, Gill, Henry (Paul), Henry (Prosper), Loewy, Rayet, Ricco, Trépied, Turner, Viniegra. There were also present, at the invitation of the Permanent Committee, MM. Abney, Backlund, Bouguet de la Grye, Callandreau, Common, Cornu, Downing, Fabre, Faye, Gautier (P.), Jacoby, Knobel, Lais, Laussedat, Newcomb, Perrotin, Scheiner, Stephan, Wolf.

Of the eighteen observatories associated for the production of the Carte du Ciel, thirteen were represented. The directors of the five other observatories, MM. Russell (Sydney), Baracchi (Melbourne), Obrecht Santiago), Cruls (Rio Janeiro), Beuf (La Plata), were prevented from attending by great distance or by professional duties.

The following officers were elected: President, M. Tisserand; Vice-Presidents, MM. Bakhuyzen and Gill; Secretaries, MM. Donner and Trépied.

The following resolutions were adopted:—

I.—PHOTOGRAPHIC CATALOGUE.

1. The Committee is of opinion that the probable error of the value of the rectilinear co-ordinates measured on the plates should be reduced to the smallest possible limits, and that the measurements must be directed in such a way that this probable error shall never exceed 0″·20.

2. (*a*) The Committee think it necessary to publish the rectilinear co-ordinates of the photographed stars as soon as possible.

(*b*) It is desirable that this publication should include the necessary information for the conversion of the results into equatorial co-ordinates.

(*c*) The Committee desires that a provisional catalogue of right ascensions and declinations should be published by those observatories which have sufficient funds at their disposal.

3. Each observatory will be at liberty to choose the positions of the comparison stars in the catalogues which seem to them most suitable. For the calculation of the constants of a plate, a minimum of ten comparison stars should be adopted if possible. The adopted positions of these comparison stars will be published.

4. The question of determining whether, for the reduction of the stars to 1900, it would be advisable to adopt a uniform system of constants for the observatories, will be the subject of a subsequent discussion.

5. The Committee recommends the adoption of a uniform size of publication for all the observatories; the size should be that of the volumes of the catalogue of the Paris Observatory.

6. The observatories will be at liberty to determine the photographic magnitudes either by measurements or by estimation. The only con-

dition which the Committee think it necessary to impose is, that the system of photographic magnitudes on which the measures or estimations depend, should allow of a precise definition, so that the different scales used in the different observatories can be reduced to a common system.

II.—The Photographic Chart.

7. Every observatory will be provided with a scale of density, which will be printed on the plates at the same time as the *réseau*, and which will permit the determination of the sensibility of each plate for luminous sources of different intensities.

Captain Abney is charged by the Committee with the construction of the scales.

8. For the construction of the chart, the second series of negatives (that is to say, those of which the centres have odd numbers for their declinations) will be made in three exposures, each lasting thirty minutes. This time of exposure may, of course, be reduced if an increase of the sensibility of the photographic plates be secured.

9. The Committee allows photogravure on copper as a means of reproducing the chart. The negatives to be exposed three times, and enlarged to twice the original size.

10. The observatories will make two positives on glass by contact, one of which will be placed in the Pavillon de Breteuil, the headquarters of the International Bureau of Weights and Measures.

11. The Committee defers till the next meeting the examination of the measures which it may be necessary to take with the object of assisting those observatories which may anticipate a difficulty in completing their programme.

The meetings of the Committee were marked with the greatest cordiality, and with the desire to carry to the end the great work undertaken in common; the decisions, prepared by special sub-Committees, were passed unanimously by the members present.

The conference was followed by a *soirée* on Saturday, May 16, and by a dinner given the next day (Sunday, May 17), in the large gallery of the Observatory, at which the following were present:—MM. Ramoand, Minister of Public Instruction; Bertrand and Berthelot, Permanent Secretaries of the Academy of Sciences; Cornu and Chatin, President and Vice-President of the Academy; the members of the Committee, and numerous visitors belonging to the Academy, the Bureau des Longitudes, the Council of the Observatory, and the *personnel* of the establishment. Professor Backlund, Dr. Downing and Professor Newcomb, members of Conference on fundamental stars, were also present.

POSTERS AND PHOTOGRAPHS.

[The Studio.]

If you set out to advertise certain things for sale, it is no use to do so in a modest, retiring way. Audacity and arrogance befit a placard, and if the man in the street jeers at blue-haired maidens, or emerald green skies, do not assume too hastily that the artist who employs them has blundered. There are many ways of attracting notice, and eccentricity is by no means a reprehensible quality in advertising. The difficulty is to be eccentric and yet to keep within the bounds of good taste. But a few years ago the damozel beloved of the Burne-Jones school would have stood no chance of finding favour in the eyes of those who advertise. Now she is the popular heroine of the moment. That she will stay so for long is neither likely nor entirely to be desired; but, inasmuch as the idea which governs conventional decoration is thereby advanced a step, one does not grudge her her hour of popular applause; for to-day, when the photographer bids fair to infect the masses with his erroneous belief that direct imitation is the end of art, it is good that in ways which appeal to the million a totally opposite doctrine should be preached. To "press a button," nay, even to "do the rest" oneself, is not necessarily to become the peer of Rembrandt or Titian, nor even of a poster designer. The bold camera-wielder claims to be the perfect draughtsman, he laughs to scorn the simplified drawing of the decorative school, the while he despises the stippled finish of the old miniaturist. As well might a maker of mirrors proclaim himself a greater painter than Reynolds; undoubtedly he reflects more of the person that gazes into his looking glasses than any artist ever set down; neither the fleeting reflection, nor the image chemically retained, have aught to do with drawing, and the ideal they exalt is not one essentially connected with art.

Gleeson White.

THE ENAMEL PROCESS ON COPPER AND ZINC.

[Eder's Jahrbuch.]

During my last year's visit to Germany, France, and England, for purposes of study, I observed that in many places efforts were being made to take advantage of the well-known American copper enamel process for the production of zinc process plates. It delighted me to co-operate in these efforts, and upon my return to Vienna I took the matter in hand.

It was at once evident to me that, in applying the process to zinc, an essential modification was necessary, principally on account of the fact that zinc will not stand so high a degree of heat as copper. How far this circumstance would influence the principal foundation of the process was still unknown to me. But to every operator it must be clear that a workable, reliable process for zinc, similar to the enamel process, must possess high practical value. Not only is zinc five times cheaper than copper, but such a process would be a considerable improvement in comparison with the asphalt or transfer methods in regard to quality and quickness of production.

All my experiments were carried out, both on copper and on zinc, and comprised reproductions of oil paintings, water colours, Indian ink, and charcoal drawings, also phototypes of various line drawings. Concerning the photographic process adopted, the following may be noted:—

The exposures were made exclusively by electric light (6000 candle power), and on wet collodion. For the colour subjects Dr. Albert's isochromatic collodion was used in conjunction with a yellow screen. The other exposures were made with a twenty per cent. bromo-iodised collodion. The sensitising bath was a solution of nitrate of silver 1 in 12, and the developer a two per cent. solution of iron and copper. The first intensifier consisted of 5000 parts water, 180 parts sulphate of iron, 90 parts citric acid, and a few drops of a 1 in 12 solution of nitrate of silver. Fixing: Cyanide of potassium solution 1 in 20. The negatives were blackened with chloride of gold, 1 part in 2000 parts of water, and 10 parts of hyposulphite of soda. The lens was a Zeiss Anastigmat, type *f*·9, focus 690 mm., the largest circular stop No. 128 = 68 mm., the smallest No. 2 = 8 mm. diameter.

For the process negatives, an etched, cemented, cross screen, by Levy, with fifty-three lines to the centimetre, was used. The distance of screen from plate was, as a rule, 4 mm., but, with flat subjects, 7 to 8 mm. distance was given. The exposures were made with two stops, namely, with No. 2 or 4, for about one-third the time, and with No. 32 or 64 for the remainder.

The total exposure was from six to ten minutes, according to subject. The negatives were reversed in the following manner: The negative was coated with plain collodion, dried, the edges lifted with a needle and then immersed in a dish of clean water. In about ten minutes the film floated off, was taken up on a stiff sheet of paper, and transferred to a glass plate coated with gelatine. The negatives were of good density, and with clear glass. No retouching was done.

After I had made several experiments with various sorts of commercial fish glue, which, on account of their valuable properties in respect of consistency and chemical impurities, led frequently to unsatisfactory results and rendered the process uncertain, I at last fixed upon the receipt of Professor Valenta, of the Vienna Technical Institute, which is a preparation of Cologne glue. According to the same, 100 grammes of good Cologne glue are soaked for twelve hours in 600 c. c. of water, and then melted in a water bath; 3 grammes of dry egg albumen are then dissolved in a little water, added to the glue solution, and the temperature raised to 100° C. for fifteen minutes on a water bath. Filter and allow to cool; 60 c. c. of this solution are then mixed with 3·5 grammes of dry egg albumen dissolved in 30 c. c. of water, and to this is added in the dark 30 c. c. of a ten per cent. solution of bichromate of ammonium. Again filter the solution. According to my experince, this solution may be kept three or four days in a dark, cool room.

Before coating, the zinc and copper plates were cleaned with alcohol and moderately warmed. A sufficient quantity of the sensitised solution was then poured upon the plate in the same way as coating glass with collodion. The plate was then transferred to the whirler, which had previously held a warmed lithograph stone. It was then whirled until dry, which usually takes from four to five minutes.

As dust is a very troublesome companion in this manipulation, I cover the plate with a hood of cardboard. At each of the four corners of the plate I place a small piece of blotting-paper, which absorbs the solution thrown off by the whirler. Printing was done by daylight only, and took forty-five to sixty seconds in the sun, and five to eight minutes in the shade, according to the light, on very dull days up to fifteen minutes was necessary.

The development was first done in clean water, and took thirty to forty seconds. To ascertain clearly the degree of development, I then bathed the plate in a solution of new Victoria green, prepared by the Badische Anilin and Soda Fabric. If the development be correct, the plate is washed under a spray, again stained with the dye, and allowed to dry spontaneously. All the detail can now be seen upon the plate in an intense green colour, and every plate that has failed can be at once cleaned off without burning in.

For burning in I use a long gas-heater with an iron plate, 1 centimetre thick, on the top. With full pressure of gas a heat is evolved exceeding the melting point of bismuth (264° C.), and below the melting point of thallium (290° C.). I conclude that the heat must be about 270° to 280° C. By lowering the gas I can reduce the heat below the melting point of tin (280° C.). The developed plate is placed upon the plate of iron, and the following changes are observable: Rather below 150° C. the colouring matter disappears, and the film begins to appear yellowish, it then passes to light brown, and with full power of gas, in about three minutes, turns to a chocolate brown. The image on these burnt-in copper plates I have found a complete protection against any solution of chloride of iron, until the process plate is full etched, and, of course, without any further preparation. But this did not concern me much, as this process is well known. My object was to employ a bichromated glue process that would be more trustworthy and simple than any other.

But, of course, it was, above all, necessary to keep in view that the structure of the zinc in producing the enamel should not be injured, which would infallibly be the case if the temperature were raised as high as with a copper plate, to reach the dark brown stage in the film of glue. I thought that I might attain this, perhaps, for practical purposes, without producing an enamel.

After many failures, I arrived at the following result:—The bichromated glue picture on zinc was developed and stained, as already described, and then laid upon the iron plate of the gas-heater. Somewhat below 150° C. the colouring matter disappears; at the melting point of Sandarak (about 150° C.) the film turns somewhat yellow, and at this point the zinc plate is removed. (In future I shall so arrange the gas-heater for hardening the film on zinc plates so that the iron plate cannot exceed a temperature of 150° C.). The film has now attained a condition in which it can withstand a first etching with 400 grammes of alcohol (forty per cent.) and 5 grammes of chemically pure nitric acid. According to subject, the strength of image, and degree of development, the etching should last from three to five minutes. As soon as all details in the shadows are plainly visible, clear and open, and the etching is sufficiently deep to permit of the plate being rolled up, the first etching is stopped. The plate is then washed with water, gummed, and dried. It is then treated with a soft, wet sponge, rolled up with fatty ink, dusted with finely powdered dragon's blood, and the latter is then fixed by heat. The second etching is with a two to three per cent. water etching solution, and lasts about five minutes. The plate is again washed, and once more placed in the above-mentioned alcohol etching solution for two to three minutes. With correct exposure and development, the entire etching of a process plate of quarto size does not take more than thirty to forty minutes. The plates are sharp and clean, and faultless prints can be made from them in the Schnell press. In the reproduction of line drawings the first etching is done in the same way, and the final etching after the usual manner for line work.

I may remark, in addition, that, if much over-exposed or too little developed, the plate may be etched with the alcohol bath, strengthened by addition of 1 to 2 grammes of acid. If, in much over-exposed plates, the details in the shadows still fail to appear, the plate may be laid in a one to one-and-a-half per cent. water etching bath for a minute or two, in which all detail will come up. With much over-exposed copper plates I have obtained good results in the following manner:—The enamelling is stopped when the film turns brown, and the plate immersed one to one and a half minutes in a chloride of iron solution, 40° B. It is then washed, and the burning-in is carried to the dark-brown stage, when it is at once finished in a chloride of iron solution, 40 to 45° B. I have also fully burnt-in at once, and then etched, first with a 35° bath, and finished with a 42 to 45° solution. The results were quite satisfactory. Much over-exposed plates can also be developed in warm water at 18° to 20° C. I have also observed that the above-mentioned bichromate of glue formula answered admirably for copper plates, but, if the same consistency upon zinc plates, it gave trouble in development. This was obviated by adding twenty-five per cent. of water. I think this may be explained by the fact that the copper plates have a much more homogeneous surface, whilst the somewhat porous nature of the zinc retains too much of the glue, and the film becomes too thick.

With reference to the production of enamel on copper plates, I have found that, in using Cologne glue, as well as other sorts of commercial fish glue, the plate should not be heated above 280° C. for production of the enamel. At the melting point of bismuth the uncovered portions of the copper plate become as white as silver, and the film brown; the film then gradually turns dark brown, and the copper assumes a reddish hue. By further heating to the melting point of lead, the plate begins to oxidise. The film of enamel begins to peel, and at last flies off.

If, in my experiments, I have contributed a small addition to the elucidation of this subject, and have given a useful hint in working out this bichromated glue process on zinc, I shall be satisfied. I must, however, expressly state that, like others, I have failed in producing an enamel process on zinc, as it is understood with copper; but I believe that the bichromated glue process on zinc is of practical value, worked in this simple and reliable way.

G. Fritz.

DEATH OF MR. WILLIAM ENGLAND.

We are sorry to have to announce the death of Mr. William England, which occurred a few days ago, at the age of sixty-six. The deceased gentleman had a long association with photography, which he took up in the Daguerreotype days. In later times he acquired a well-deserved reputation for his landscape work, and was renowned for his Alpine views, which for a long time remained unapproached. Some of his instantaneous street scenes, taken, we believe, so long ago as the year 1858, are not excelled even at the present day. Mr. England may be described as one of the old school of photographers, the ranks of which are rapidly thinning, and he was universally esteemed. In former times, as our back volumes testify, he made many contributions to technical photographic knowledge. For many years he was a member of Council of the Royal Photographic Society, of which he was a warm supporter, and at whose exhibitions he was a frequent exhibitor.

News and Notes.

The Photographic Club.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock on Wednesday evening, August 26. The subject for discussion will be, *The Best Basis for Judging at Photographic Exhibitions.* Visitors are welcome.

Leytonstone Camera Club.—The Hon. Secretary writes: "I regret to inform you that the studio of the Leytonstone Camera Club was destroyed by fire on the night of August 10, including the whole of the Club property. Fortunately the latter was fully insured. Would you be kind enough to intimate that, whilst arrangements are being made for new premises, all communications should be addressed to the Hon. Secretary, 110, Windsor-road, Forest Gate, E.

Soldering glass by means of a metal solder has become a possibility through a recent discovery of an alloy, composed of ninety-five parts of tin and five of zinc, which melts at a low temperature and will firmly adhere to glass. Another alloy of tin and aluminium, containing ten parts of the latter, melts at 390°, and can be used also for soldering glass. Either of these alloys can be cast upon glass without danger of breaking the glass if it has been previously heated slowly. Castings of these alloys made on glass become firmly adherent, as much so as though they were made on metal.

When the Princess of Wales intends to visit the photographers, says a contemporary, she usually arranges that her sitting shall take place in the morning. A special studio is set apart for the Princess and other members of the Royal Family. It is approached by a private door, which leads to an ante-room provided with easy-chairs and a plentiful supply of illustrated papers. A small chamber is fitted up as a dressing-room, and here is to be found a maid from Marlborough House, who, has preceded her Royal mistress with a dressing-case containing all toilet requisites. The Princess, having decided on the position in which she wishes to be taken, arranges herself. It is etiquette on these occasions for the photographer to address any remark he may have to make to the lady-in-waiting in attendance, who in turn addresses the Princess, who replies through her.

Photometry of Coloured Lights.—An ingenious and simple method of comparing the luminosities of differently coloured lights is described by Frank P. Whitman in the *Physical Review* of recent issue. The principle on which Whitman's photometer is founded is due to Professor Rood. Rood prepared about fifty grey discs, differing successively in depth of tint from black to white. If a dark shade was combined with a light shade in the usual way, and rotated rather slowly, the familiar unpleasant sensation known as a "flicker" was produced; but, if successive pairs, more and more nearly alike, were chosen, the flicker became less, until it almost, or quite, disappeared. Nearly the same effect was produced if, instead of a grey, some other colour was substituted on one of the discs. It was always possible to combine with a grey disc of such a shade that the flicker nearly ceased, showing that this sensation is apparently independent of the wave-lengths of the lights compared, and dependent only on the relative luminosities. In Whitman's instrument, a coloured card and a white card are alternately exhibited to the eye of the observer. These cards are illuminated by lights of different intensities placed at opposite ends of a graduated photometer bar. By moving the support on which the cards are fixed along the photometer bar, a point is reached at which the "flicker" ceases. At this point the illumination of the white disc or card is taken to be equal to that of the coloured card, and the relative intensity of the sources of light can be calculated. Of course, instead of a coloured card, a coloured light may be subjected to measurement. This instrument is said to give results quite as good as are obtained when two lights of the same colour are compared by the ordinary photometer.—*Scientific American.*

Photography in Colours at Newquay.—Mr. G. G. Bullmore writes to our Newquay contemporary, whose remarks we quoted last week: "I have read with interest your reply to my challenge in this matter, and much regret to note that Mr. Bennetto regards my letter 'as based on the implication that he does not speak the truth.' I wish emphatically to disabuse his mind of any such intention on my part, as my challenge was addressed to yourselves, and I have not yet heard from Mr. Bennetto, privately or publicly, that *he* claims to have discovered 'photography in colours of nature by purely photographic means.' I was under the impression that your article, 'A Grand Discovery by a Newquay Photographer,' in your issue of the 24th ult., was based upon error, and embodied your own ideas and impressions. Seeing that a large amount of scepticism has always been manifested on this subject, you will, I think, forgive me if I considered that your good selves are scarcely qualified to give an expert opinion. The reasons of my friend and myself holding such a view may be summed by the following extracts from an article on 'Photography in Colours,' published in *Chambers's Journal* of May 9 last, wherein the writer makes the following statement: 'Again and again has it been asserted that the problem of photography in the colours of nature was solved. Companies have been formed to purchase secrets which were known only to one man, who recognised the value of that commercial doctrine which teaches that where there is a demand a supply is sure to follow. Within the past twenty years half a dozen such projects have been brought before public notice, people have believed in them, and have invested their money in them, but we are still as far from photography in colours of nature as were Daguerre and his contemporary workers of half a century back.' After stating that 'advances have been made in the better rendering of coloured objects,' he proceeds as follows: 'But all this progress in the art, satisfactory though it be, brings it no nearer the solution of the problem of photography in the colour of nature. True it is that there are many methods by which photographs are printed in colours, and very effective some of these pictures are, but they employ coloured inks or pigments of some kind, and, although they have a photographic foundation, it would be false to describe them as photographs in colour.' I wish further to state that I appreciate Mr. Bennetto's scruples on the question of its being a 'common street bet,' but I cannot plead guilty to

the offence, and nothing was further from my mind. Personally I do not consider I was justified in declining to accept the deposit of the twenty guineas for the benefit of a public institution under the conditions named. I note that you have not furnished me with the names of the 'leading scientists and distinguished persons' who have seen the results and 'declared them marvellous.' Had you done so, and I had found amongst them men whose judgment I can trust in such a matter, the twenty guineas would have been forthcoming without further trouble. Seeing that Mr. Bennetto has not denied or qualified your statement, but has, through you, taken the matter up personally, my friend is prepared to pay the sum of *fifty* guineas against yours, or Mr. Bennetto's twenty-five guineas, upon the conditions laid down in my letter published in your issue of the 31st ult.; and permit me to hope that you will endeavour to overcome Mr. Bennetto's scruples, and that you will appeal to Mr. Bennetto, who must take a deep interest in the welfare of the town, to obtain for its benefit the substantial sum now offered by my friend. After reading the articles in THE BRITISH JOURNAL OF PHOTOGRAPHY on *Photography in Colours in the Lantern*, Mr. Bennetto will scarcely ask the referee to accept that mode of demonstration."

Patent News.

THE following applications for Patents were made between August 5 and August 12, 1896:—

CLEANING PLATES.—No. 17,185. "An Improved Method of and Apparatus for Cleaning and Preparing Photographic Plates and Films." B. J. EDWARDS.

MOUNTING.—No. 17,189. "Improvements in or relating to the Method of and Means and Appliances for Mounting Drawings, Photographs, Stamps, Etchings, and the like in Albums, Mounts, and analogous Articles." H. J. JOHNSTON-LAVIS.

FOLDING CAMERAS.—No. 17,217. "Improvements in Folding Photographic Cameras." W. W. BEASLEY.

EMBOSSING.—No. 17,225. "Improvement in the Method of Embossing Photographs." Complete specification. F. A. TABER.

STEREOSCOPIC APPARATUS.—No. 17,388. "Process and Apparatus for Taking and Reproducing Photographs with Stereoscopic Effect." T. J. PERRETT.

CAMERAS.—No. 17,505. "Improvements in or relating to Photographic Cameras or Film-exposing Apparatus." T. H. BLAIR.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

August.	Name of Society.	Subject.
24	North Middlesex	Demonstration by the Autocopyist Co.
25	Birmingham Photo. Society	The President (Sir J. Benjamin Stone, M.P.) will attend to Distribute the Medals and Certificates gained at the Annual Exhibition.
25	Hackney	Open Night and Demonstration.
26	Photographic Club	The Best Basis for Judging at Photographic Exhibitions.
29	Birmingham Photo. Society	Excursion: Worcester. Leader, G. A. Thomason.
29	Borough Polytechnic	Excursion: Barnes and Richmond.
29	Croydon Camera Club	Excursion: Greenwich. Leader, W. H. Rogers.
29	Croydon Microscopical	Conversational Meeting and Excursion Results.
29	Darwen	Excursion: Ball Hill and Moor. Leader, J. W. Smith.
29	Leytonstone	Excursion: St. Margaret's. Leader, G. Campbell.
29	South London	Excursion: Kew and Richmond. Leader, M. Boxall.

PHOTOGRAPHIC CLUB.

AUGUST 12,—Mr. J. E. Hodd in the chair.

Mr. J. S. LANE, an American gentleman touring in Europe, and who had previously been a visitor to the Club, was present. He stated that since his last visit he had been to Madeira, the Cape, and the Transvaal. He was in Johannesburg at the time of the dynamite explosion, and got some pictures within a few hours of that event. He referred to the very great difference in the actinic power of the light here and in South Africa. He found the light there stronger, in a photographic sense, than it was in the United States. Among other interesting items mentioned by this visitor was a method which he employed to utilise dark-room lamps fitted with a candle and actuated by a spring. He said that, by wrapping a rag or duster soaked in cold water around the lamp and the socket containing the candle, he was enabled to prevent the candle becoming soft, and being pushed through the top of the lamp.

Mr. Tottem showed an album of prints. The pictures were printed upon matt Solio paper, and were toned with platinum in accordance with the Eastman Company's printed instructions. The pictures were excellent, both in an artistic and technical sense.

Being an Open Night, the meeting became of a conversational order. Mr. Hodd gave further details and particulars of some dark slides which possessed the characteristics of producing foggy marks upon plates which were left in them for any length of time. These marks were of an uncertain origin. Apparently, they were produced where the shutter of the slide was hinged, but sometimes the marks were light and sometimes dark. There was no obvious connexion between them and the light outside the slide. They were equally noticeable when the slide and the plate it contained were kept in the dark room. Every one to whom he had related the particulars had a theory which accounted for the trouble. The explanations, however, were all different. Mr. Hodd promised to send up some of his experimental results to the next meeting of the Club. Having once started the question of photographic troubles and mishaps, every member had a full budget of disasters and experiences to relate.

Mr. Lane promised to bring up to the Club some of the results which he had obtained upon his recent tour, and Mr. Charters White wrote stating that Mr. Noel Cox had kindly promised to give the Club a Travellers' Night during the approaching winter session.

Hackney Photographic Society.—August 11, Mr. W. Rawlings presiding.—Several new books were added to the library, making considerably over 200 books. The evening was set apart for the few remarks on Multiple-coated Plates by Mr. SANDELL, who said the anti-halation powers of these plates were not all that was claimed for them, as they would, in a great measure, make over-exposure almost an impossibility. Many questions were asked, to which Mr. Sandell replied. The speed of the various films on the plates were as follows:—Top, extreme rapidity; second, medium; third, slow lantern plate. He had not adopted the Hurter & Driffield method. The top film would, for rapidity, compare with any in the market. He advocated the use of metol as a developer. In hot weather, it was better to use the alum bath. Some experiments were made of plates having had exposures varying from half a second to thirty-two seconds, and were successfully developed in the same dish. A great number of prints were passed round and bore out the inventor's claim of the anti-halation powers of the plates.

South Australian Photographic Society.—The Annual Meeting of the South Australian Photographic Society was held at the Chamber of Manufactures on Thursday evening, July 9. Mr. E. W. Belcher presided. Miss Perryman was elected a member, and four nominations were received. Mr. Clough and Mr. Stace showed specimens of work for criticism. The programme for the coming year was read by the SECRETARY, also the eleventh annual report, which contained the following:—"The number of members on the roll is now sixty-nine. Seventeen new members were elected during the year, three resigned, and three were struck off for non-payment of subscription. Two slight alterations of the rules were made, one to provide for two Vice-Presidents, and the other to make Librarian also Assistant Secretary. During the year the Secretary and Librarian resigned their offices, and these positions have since been filled by Mr. J. Gazard and Mr. J. D. Dixon. The Society's stock of apparatus, &c., has received the addition of two table gas lamps, a strong box for storing the Society's papers, &c., and portable bookshelves. The library has been further extended by the addition of fifteen books, besides periodicals, the total number of volumes on the catalogue now being eighty-two. A complete rearrangement of the library has just been made, all the books procurable having been called in and renumbered. During the year eleven ordinary and ten committee meetings have been held. The attendances have been very satisfactory, and the specimens of work shown by members for criticism have been numerous, and some of exceptional merit. The annual *conversazione* was held in the Victoria Hall on September 12. It was largely attended, and proved a complete success. On February 29 an excursion was made to Mount Barker at the kind invitation of the Hon. Dr. Cockburn. This is the fifth year in succession that the Society has benefited by the doctor's kindness. On this occasion over twenty members accepted the invitation, and spent a thoroughly enjoyable day. The Society contributed to the success of the Mayor's *conversazione* in November by an excellent display of photographs and apparatus." The Treasurer read his annual statement, which showed a good credit balance. The report and balance-sheet were unanimously adopted. The retiring President, Mr. E. W. Belcher, delivered the annual address, and made reference to the progress of photography, the discoveries of the year, and the future of the art. The election of officers for the ensuing year resulted as follows:—*Patrons:* Sir Thomas Fowell Buxton, Bart., K.C.M.G., Hon. Sir E. T. Smith, K.C.M.G., M.L.C., Hon. Dr. Cockburn, M.P., Professor E. H. Rennie, M.A., D.Sc., Professor W. H. Bragg, M.A., and Mr. J. J. Green.—*President:* Mr. A. W. Dobbie.—*Vice-Presidents:* Messrs. A. Scott, B.A., and A. H. Kingsborough.—*Committee:* The executive officers and Messrs. C. F. Clough, A. W. Marshall, and S. P. Bond.—*Hon. Librarian and Assistant Secretary:* Mr. J. D. Dixon.—*Auditors:* Messrs. C. Radcliffe and Kerr.—*Hon. Treasurer:* Mr. R. B. Adamson.—*Hon. Secretary:* Mr. J. Gazard. A hearty vote of thanks was accorded to the retiring President; also to the Treasurer for his seven years' services.

Correspondence.

OPACITY OF WET AND DRY NEGATIVES.

To the EDITORS.

GENTLEMEN,—I am very pleased to see that at least one of your readers has taken an interest in the question of different densities of wet *versus* dry gelatino-bromide plates.

The experiment he has suggested is certainly an interesting one, and I venture to think that very little difference will be found between the

density of the stained gelatine, wet or dry; of course, water absorbs a certain amount of light, but that will not account for the difference manifested in a gelatino-bromide plate. I rather suspect that the arrangement of molecules of the silver bromide has much to answer for.

Another matter bearing on this subject is the fact that a gelatine negative, when dried, after the application of alcohol, is more intense. This is easily proved by cutting a negative in twain (one that has not been dried), treat one half to a dose of alcohol, then allow both to dry spontaneously. Rapid drying by heat increases density. Opaque substances, as a rule, when mixed with a large quantity of transparent vehicle, lose a good deal of their opacity. Bromide of silver seems to be one of the exceptions. If I double the quantity of gelatine to a given amount of silver bromide, I get more speed. I account for this by the greater separation of the solid or semi-opaque matter.

Again, if I take a negative that is just surface-dry, and place it over the fumes of a strong solution of cyanide of potassium, the image will disappear entirely if left long enough. Where has the silver gone, or in what state is it? Certainly not visible, and no subsequent intensification will bring it up as it was originally. A glance along the surface will show that, where the negative has been exposed to the fumes, it is more glossy, leading one to imagine that the silver is evanescent. Apologising for taking up so much of your space, and thanks to your Capri correspondent.—I am, yours, &c., A. L. HENDERSON.

277, *Lewisham High-road, S.E.*

THE HYPO FIXING BATH.

To the EDITORS.

GENTLEMEN,—Your correspondent, "Alpha" asks me to state what, in my opinion, is a suitable strength for a hypo fixing bath. For negatives I consider one part by weight of hypo to five parts of water suitable; temperature, 60° Fahr.; and time ten to twelve minutes. For gelatino-chloride prints I like my solution weaker, say, one part to seven or eight; temperature, 55° Fahr.; time fifteen minutes. I usually alkalise my fixing bath with ammonia, because the ammonia bottle (ten per cent. solution) is to hand; but any alkali will do, and, in fact, ammonia is better kept away from gold-toned prints unless they are well washed.—I am, yours, &c., ANDREW PRINGLE.

THE POISONS ACT.

To the EDITORS.

GENTLEMEN, I have just read the letter of your correspondent, Mr. Wm. Hampson. In spite of his wrathful assertions to the contrary, even pharmaceutical chemists are sometimes as ignorant on some points as you asserted. Not so very long ago, I was told by a chemist that bicarbonate and carbonate of soda were practically the same thing. I don't know what may be the difference, from a drug point of view, but, I know, any one using them indiscriminately in a toning bath, would soon find something wrong. To be calmly told, when one wants *bicarbonate*, that *carbonate* will do, and is practically the same thing, is quite enough to make one doubt the infallibility of even pharmaceutical chemists.—I am, yours, &c., C. H. HEWITT.

Catherine-terrace, Gateshead-on-Tyne, August 15, 1896.

ART AND PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—In answer to several inquiries since my letter, "Art *versus* Photography"—which should, I think, be Art and Photography—I will forward on my book, to those who have applied, as soon as printed; and, beautiful and charming as photography is, yet, on passing many photographers' windows, there is a tendency to gloom, which the art of the photographer should eradicate. I know it is the tendency of several processes, and, until one puts them side by side with other works, we do not appreciate the loss. If photographers could use their pencils as well as their cameras, they would realise more what Professor Lully says. Few who have not endeavoured to draw and paint a daisy or primrose dream what exquisite symmetry of design, what tender enchantments of melting tint will baffle them in the task that appears so easy; yet even with the vast majority, who will partially or entirely fail, the time will not be in any way lost which had been given to preliminary lessons in drawing. They would have acquired, what is so good to have, a new conviction of their own shortcomings of sense and observation; they would have perceived, as nothing else could so teach them, the wonderful variety and perfection of the natural world, and the absolute inexhaustibility of its stores of beauty and instruction.

I will write again when my stress of work is somewhat over, if I can arrange it, to see if some of you might explain more fully—for "things seen have more power than things heard."—I am, yours, &c., JOHN BOOL.

86, *Warwick-street, Belgravia, S.W., August* 17, 1896.

COLES' CAMERA FRONT.

To the EDITORS.

GENTLEMEN,—I am glad to notice in your last number that the Photographic Club have sent a contradiction to their reports appearing in the JOURNALS of January 17 and February 7, that the lens-carrier which Mr. Hare presented to them as an experimental one (and which, by the way, was not intended for the camera) was in any way like Mr. Coles' camera front, which, instead of only being fit for a club museum of relics, is a complete practical success.

I think it a pity that more care was not taken with the report, as it is entirely misleading to those who trust to the reports of the leading London clubs as to the value of new inventions.

The value of this camera was shown at the Royal Photographic Society at the exhibition of the lantern stereoscope, and, at another London Society; the discussion was entirely in favour of the front as being vastly superior to anything gone before. One has only to use it to find hitherto unknown comfort in working, being free from the restrictions of fronts which will not rise at a short focus.—I am, yours, &c., H. C. RAPSON.

11, *Shaftesbury-road, Hornsey Rise, N., August* 17, 1896.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:—

Arthur Simmons, 258, Westminster Bridge-road.—*Two photographs of cricket match at the Oval, England* v. *Australia.*

RECEIVED.—Cadett & Neall; Percy Lund & Co.; J. Lewis; "Background" "Mercury"; "Electric;" and others. In our next.

F. WAREN.—Thanks; you will observe we have utilised the extract.

PLASTER CASTS.—F. E. G. We should advise you to send the casts to a maker of such things.

DIRECTORY OF PHOTOGRAPHERS.—ANNIE WOOD. Messrs. Percy Lund & Co., Bradford, publish such a work.

PYRO STAINS.—J. W. We fear the stains are not easily removed, but the cautious use of solution of alum and hydrochloric acid, oxalic acid, or alum and citric acid, might answer.

LENS.—PITT & SON. Sorry it is against our rules to answer questions such as yours. We should advise you to consult the catalogues of makers of repute; but we should be pleased to help you, if possible, on any specific point.

VENICE TURPENTINE.—M. CONNOR. Venice turpentine is kept by most oilmen who make a speciality of varnishes, also by most drysalters. We should not, however, recommend you to add any of it to the varnish you name. Instead of improving it, you will be doing just the reverse.

GASOLINE.—S. W. DIGBY. The *Ironmonger* is clearly under a misapprehension. The material is not used in any way in photography. We should say that the best sources to apply for it would be some of the petroleum refiners. Wherever it is supplied from, we suspect there will be difficulties as to carrying restrictions.

DAMAGED BACKGROUND.—J. MOORE. We strongly suspect that you will not be able to get rid of the stains caused by the rain coming through the roof, now that the background is dry, except by having it redistempered. If, while the background was still wet with the rain, it had been thoroughly wetted all over with a water can, the probability is that it would have dried without showing any trace of injury.

EXPIRED COPYRIGHT.—The copyright in the engravings has expired long ago, and they are very scarce now. If you make lantern slides from the original engravings, you will be all right. That may not be the case, however, if you make slides from any of the modern reproductions of them, of which there are several. There may be a copyright in the different reproductions, though there is none in the originals.

LEAKY ROOF.—S. SIMCOE. Yours is no uncommon experience after such heat as we have had during the summer. However, as the studio was only built in the spring, we should surmise that a couple of coats of paint, on the outside, will make the roof waterproof again—that is, provided the best materials were used in its construction. We should advise you to consult the builder who erected the studio in the matter.

RESIDUES.—WASTE says: "Some time ago you suggested putting the gold bath (sulphocyanide) with the used hypo baths, but I do not think you mentioned the method by which you propose the gold and silver should be thrown down together. Must I add liver of sulphur and sulphate of iron also? I shall be obliged for an answer in the usual place. I have been putting these baths together for some time in a lead-lined trough, formerly used for washing prints."—Liver of sulphur alone is sufficient. If the baths have been standing long in the leaden vessel, we should suspect that the precious metals, or a large proportion of them, are already reduced to the metallic state by contact with the lead.

*** Many answers to correspondents unavoidably held over

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1895. Vol. XLIII.—AUGUST 28, 1896.

Contents.

OUR FORTHCOMING ALMANAC.

The time of year has arrived when it is necessary for us to take in hand the preparation of The British Journal Photographic Almanac for 1897. A feature of the volume for the past thirty years has been the co-operation of numerous friends and readers of the Journal, and the Editor takes the opportunity to express the hope that the support so kindly placed at the disposal of his predecessors may be continued to him.

We especially invite contributions on topics of practical interest, and should feel obliged if the articles and any accompanying sketches are sent to us at the earliest possible date.

Secretaries of Societies, and especially of those established since the appearance of the last Almanac, will oblige us by forwarding lists of officers and other details for inclusion in the Directory of Photographic Societies, in order that the list may be made as complete as possible.

The Publishers wish us to remind intending advertisers that the announcement pages of the Almanac are already filling rapidly, and that, to ensure insertion and good positions, orders and copy should reach them without delay.

EX CATHEDRÂ.

Mr. Byrne, of Richmond, is good enough to send us a copy of a circular he has received from a well-known firm of diarists, who, in referring to an almanac they are about to publish, say: "In it we are placing a coupon, on presentation of which at certain photographers' throughout Great Britain the bearer will be entitled to one cabinet portrait free of charge, and shall be pleased to add your name to the list, which will cost you nothing, on the understanding that you will honour any of the said coupons that may be presented before the end of 1897. As in every instance other copies will undoubtedly be ordered, and further business result, this must prove a splendid advertisement for you. We only appoint one photographer in each district, so shall be glad to hear from you per return."

* * *

We are not astonished to be told by Mr. Byrne that he declines to entertain the proposition. The firm certainly offer photographers a free advertisement, although some may think it is not one by which they are likely to profit, either in money or reputation. The presence of a photographer's name in the list may not inform the public in so many words that he has agreed to take photographs for nothing; but, as he is to depend for his profit upon the copies that will "undoubtedly (?) be ordered," it would be a very dense sitter who did not straight away see through the arrangement. It remains to be seen whether the firm's offer is one to commend itself to the favourable consideration of photographers of any class or standing, but the idea all through strikes us as being hardly calculated to advance the interests of the photographer although it may benefit a book such as the authors of the circular are advertising.

* * *

We are informed that the National Research Society has awarded its gold medal to the London Stereoscopic Company for practical demonstrations connected with the application of the Röntgen rays to surgical diagnosis. The Company, who were early in the field with practical radiographic work, deserve the medal; but we should be glad if any of our readers would oblige us with some information respecting the National Research Society, of which, we must admit, we never before heard.

Messrs. Whittaker & Co., of Paternoster-square, send us the programme of the Technological Examinations for the Session 1896-97, held by the City and Guilds of London Institute. It is a volume of over 300 pages, price 10*d.*, and it need hardly be said that photography finds a place among the subjects treated of. In another part of the Journal we give the syllabus of next year's examination, as well as the questions set at that which was held last May. The questions set in the photo-mechanical branch strike us as difficult to improve on; but we think that those selected for ordinary photography are here and there open to objection. As an example, the Artigue process, of which it is sought to test candidates' knowledge, amuses some half-dozen dilettanti photographers, but is scarcely likely to win serious consideration as a printing method, and we are, therefore, at a loss to know why it was thought necessary to refer to it.

* * *

There were other questions set in this — the Honours — grade that assumed a degree of knowledge on the part of the candidates which they were hardly likely to possess. For instance, they were asked to describe the composition and manufacture of celluloid as used as a support for gelatine emulsion. The text-books tell what celluloid *is*, but, as it is not, we believe, manufactured in this country for emulsion purposes, the part of the question that asked for information on that point is practically impossible to answer.

* * *

"The causes of the phenomenon known as the reversal of the image" are not yet precisely understood; at any rate, we are safe in saying that our foremost scientific investigators who have studied the phenomenon are not agreed as to the causes, so that the question is one to which none but speculative replies could be given. If it is customary for examiners to set questions that do not admit of definite answers, we would suggest the abandonment of the practice, inasmuch as, the object of the examination being presumably to test the candidate's knowledge of *practical* photography, the introduction of matters of disputed theory is superfluous. We may note, in conclusion, that the candidates were asked to describe "the" process of producing burnt-in enamels on porcelain. The candidates would be quite entitled to rejoin, "Which one?" There is more than one such process; but the ways of examiners are difficult to comprehend, a conclusion to which most of us were driven comparatively early in life.

PRINTSELLERS' PHOTOGRAPHS.

By this title we would wish to be understood as referring to the photographs adapted for exhibiting for sale in the printseller's shop, in contradistinction to those produced in the usual routine of the professional photographer's studio to his sitters' orders. It may be that to many the term will be meaningless, that it will suggest nothing in the way of business or of profit. But things were not always thus. The pioneers of popular portraits for the million could tell the present generation of photographers of orders that would be well-nigh incredible. It is on record that, in the early days of the *carte-de-visite*, when popular characters were to be seen exhibited in every print-shop window in the kingdom—and were, moreover, sold quickly at 1*s.* 6*d.* a piece, and were to be seen in almost every album in the kingdom—it is on record that an order for a hundred thousand copies of Her Majesty was placed in Mr. Mayall's hands: a hundred thousand *cartes*, invoiced possibly at 9*s.* or 10*s.* per dozen, and printed from wet-plate negatives without any retouching, twelve repeat portraits on each plate! We are now writing of a period of upwards of three decades ago, when it was actually the fashionable thing to be photographed, and fill one's album as quickly as possible with an equal proportion of friends and of public characters. Gradually, however, the craze—for such, indeed, it was—subsided. till it was once more given a fresh lease of existence in a different direction, portraits of pretty popular actresses and singers being chiefly in demand. After a while, when this fashion had had its day—Soho-square could give a good account of the millions of pictures sown broadcast from its distributing centre—the popular fancy was for portraits of society belles, which had such an immense run that it was reported that some of them were paid large sums for the privilege of photographing them, and a new slang expression was adopted into the language of the day—"professional beauties" these sitters were termed. It was said that they were as well paid as the actresses, to one of whom—Mrs. Rousby, in "'Twixt Axe and Crown"—it was currently rumoured that no less than 200*l.* was paid for the sole privilege of photographing her and selling her portraits.

Since that time, with a few exceptions, the sale for this class of picture, with a few occasional brilliant exceptions, has fallen lower and lower, till, we opine, an order for a hundred pounds' worth of copies of one negative would be looked upon as something quite out of the common.

It will naturally be asked, "How has all this come about?" The answer is easy to find. It is twofold: first, the cessation of a particular popular craze; and secondly, and most important, the invention of the ruled screen for process blocks. There is no doubt about the matter, the increased facilities offered for multiplication by the process block, and its quick adoption by the press, has scotched, if not killed, the business of popular character selling.

Time was when, if any one took an interest in a particular person or place, he would go to the nearest print shop and buy a photograph; nowadays, however, he says, "I will wait till I get my Saturday's illustrated paper, it will be sure to contain it." Quite recently we were in a well-known photographer's studio, and we heard a client say, while admiring a new portrait just issued, "Oh, I will wait till Saturday, when it will be in my paper, and I shall cut it out and frame it." This is nothing but a bald narration of fact, and the only question that can arise out of it is, "What is the remedy?" We know of none, and, even when there is a sale, prices are cut so low as to leave little margin for profit. There is, however, one palliative, and that is from the *fons et origo mali* itself, the illustrated papers themselves. Any one can see for himself what a poor show the weekly illustrateds would be without photographs reproduced by "process" or actual wood-engravings. Of this source of profit less use is made than might be. These papers must have illustrations and photographs to base them on; it behoves the photographer, with his eyes open, to lose no chance of securing a negative of every person, every event, every place, which for the moment is occupying public attention, and to get a print off at once to the most suitable paper. They will all accept and pay for such pictures; but speed is the very essence of the profit to be reaped. If a man becomes famous at the end of the week, there will be no demand for his portrait for the papers after

the first day of the very next week. Every one who aims at making money this way must bear in mind that the Saturday editions of these papers go to press Tuesday or Wednesday, and that some time, brief though it be, is needed to get a process block ready. In a general way, Saturday is the latest, though, for specially attractive and popular subjects, Monday may possibly be in time. The publishers then are just willing, when there is a legitimate copyright, to pay a fair price, its extent being governed by the demand for, or the rarity of, the subject photographed; but the photographer must be in time.

Last Saturday's papers offer a good example of what we mean. We have, of course, no means of ascertaining what the photographers received, but we note that portraits of Li Hung Chang, at Hawarden, on Saturday, and at Windermere, on Sunday, appear in the papers published last week, so that the plates must have been exposed, and developed, and printed from the day they were taken, and sent off the same day to London, care being taken meanwhile to make them copyright. The next step is, of course, to make the most of the negative, either locally, or, if it be of general interest, through the usual channels of publication. Here, however, will be found a woful contrast to the halcyon days we have alluded to. The best advice we can give is, Be open and fair with the papers—they are willing to give fair prices, governed, as we have said, by the subject itself—and above all, to be quick to put the goods on the market, lest they be a "day behind the fair," when their value for paper illustration purposes would be *nil*.

Li Hung Chang.—The Chinese Envoy, who has been the "lion" of Europe for some time past, has left for the States. Disappointment has been expressed on the Continent and here that he has not left business orders with any of the manufacturers whose works he has visited, although the "goods" shown him have been displayed to the best advantage. However, a few photographers have profited by his visit. While in Germany, he was photographed together with that veteran statesman, Prince Bismarck, and while in England with Lord Salisbury and also with Mr. Gladstone, two of the greatest statesmen, though of opposite politics, of this country. All these photographs have been reproduced in the illustrated press, and have proved a source of considerable profit to the photographers who took them, and will, doubtless, continue to do so for some time to come.

M. Andrée's Balloon Expedition.—Last week we commented on the conflicting telegrams received during the past few weeks as to this enterprise, such as, that the wind was unfavourable when everything was ready; that the wind was favourable, and that a start had probably been made; that the balloon was damaged; that it was supposed to have been sighted, &c. At last we have a telegram, dated Christiania, August 21, which is, doubtless, reliable. It is to the effect that, when Dr. Nansen's vessel, the *Fram*, visited Dane's Land, M. Andrée stated that the season was now too far advanced to make the ascent this year, and that he should leave Spitzbergen on the 20th inst. (Thursday last). It may be remembered that, when this expedition was first mooted, much doubt was expressed amongst scientific men and geographers as to the practicability of the hazardous undertaking, and, so far, they have proved correct. We shall see what comes of it next year. Many are of opinion that M. Andrée is safer now than he would have been if he were on his perilous voyage.

Stratford-on-Avon.—Last season, and this, the London and North-Western Railway and the Great Western have been running half-day excursions at a very cheap rate to Shakespeare's country, of which many photographers have availed themselves, as will, no doubt, many more. The fare for the double journey is but three shillings and sixpence, and allows a stay of over four hours. What we wish to call special attention to is that the former railway company gives a sketch map of the district on the back of their handbills, showing the route to be taken to see all the places of interest in the shortest time, as well as the times to get from place to place. No photographer, who visits Stratford for the first time, should fail to take one of these with him, as it will save him much loss of time, and perhaps avoid sundry "tips" to the natives. The example set by the L. & N. W. would well be followed by other companies who run such trips, as often those who avail themselves of them, particularly those with cameras, waste a deal of time in finding the places they are most desirous of seeing.

Return of Dr. Nansen's "Fram."—The ship, *Fram*, which Dr. Nansen and Lieutenant Johansen left frozen in the ice in March 1895, has arrived safely home with all well aboard. It is curious that Dr. Nansen and his vessel, after so long a parting, should arrive back within a few days of each other. It is stated that the lowest temperature experienced was about fifty degrees below zero, and the greatest depth of sea ascertained was 2185 fathoms. Dr. Nansen says that those on board the *Fram* had plenty of amusements, and well they needed them in their ice-bound quarters. We mentioned last week that Dr. Nansen and Lieutenant Johansen must have had a rough time of it on their way back; but they have no cause to complain, since, of the reception they have met with from all sides. They have been fêted and feasted with the greatest enthusiasm, and their ship was received with the greatest honours from all the other vessels in the neighbourhood. Although Dr. Nansen failed to reach the pole, yet he has got the credit of having got nearer to it than any previous explorer.

The Recent Eclipse of the Sun.—At the time of writing last week there was nothing to chronicle with reference to the different eclipse expeditions but the more or less failures—more rather than less—particularly the scientific-cum-pleasure one to Norway, on account of the weather. It is gratifying, however, to learn from later telegrams that the same has not been the case everywhere. A telegram from Hammerfest says that Sir George Baden-Powell's yacht *Otaria* had arrived there with the members of the British Eclipse Expedition, and that the party had, in Nova Zembla, secured some very satisfactory photographs. A telegram from St. Petersburg says that, with regard to the observations of the eclipse on the Amur, the sky was overcast at the time, but six photographs were taken illustrating the different phases of the eclipse. A later telegram from Russia says that the expedition sent to the North of Finland experienced magnificent weather, and it obtained ten good photographs of the corona with three different apparatus. So, after all, some satisfactory and valuable results have been secured, though the Norwegian expeditions, in connexion with which the most elaborate preparations were made, were barren.

A Society of Miniature Painters.—Miniature painting is likely to receive a fresh impetus by the formation of a Society of Miniature Painters, who intend to hold an inaugural Exhibition at the Gallery, 175, New Bond-street, about the middle of next month, under the auspices of several R.A.'s and other well-known artists. The members of the Society are to be limited to fifty professional artists. The Exhibition is to include not only portraits but miniature subject pictures not exceeding 12 × 10 inches dimensions. There is no question that miniature painting has been on the decline for many years past, indeed ever since the advent of photography. We are, of course, alluding more particularly to the "Miss La Creevy" style of portrait, which, as a matter of fact, may be said to be now about as extinct as the old *silhouette* black paper portrait. Photography practically killed both. Miniature pictures on ivory are, however, still done, and of sufficient merit to find a place in the annual Exhibitions of the Royal Academy, though they may not be quite up to the standard of a Cosway, a Sir William Newton, and others; but we hope that the new Society will be the means of developing work of a similar character to theirs.

By the way, has the colouring of photographs become a lost art? We mean the high-class work that used to be done thirty or more years ago by Lock and other artists of equal talent. That high class of work seems to have now become quite extinct. This, in some measure, may be due to the fact that the base upon which the work was put—the silver print—proved evanescent. Some prints, upon which several guineas had been spent in the colouring, were found to undergo a wonderful change after a few years. That need not be the case now; but we very much question if any large proportion of the public would pay from five to ten guineas for a coloured photograph, less than the cabinet size, if artists were forthcoming to give full art value for the money.

ORTHOCHROMATIC COLLODION EMULSION FOR PROCESS WORK.

Having recently been obliged to make half-tone negatives from a number of rather highly coloured drawings, and finding that the necessity of making first an ordinary negative upon an orthochromatic plate, and from this a silver print, and then the half-tone negative somewhat too tedious a job, I determined to try my hand at preparing collodion emulsion plates, and sensitising them myself, and, after considerable failure, success attended my efforts at last, and the following notes may be useful to other process workers.

As I knew that on the Continent an ortho emulsion, made by Dr. Albert, was used by many process workers, I first tried this, but, either from my ignorance of how to work it properly or some other cause, I did not find it quite satisfactory, there being a tendency to fogginess and want of clearness in the half-tone negative which was fatal for block-making. I therefore set to work to make my own, using the formula originally sketched out by Hübl.

Schering's celloidin was chosen for the pyroxyline, more because I knew it better than anything else, and absolute alcohol and methylated ether; but I soon found that, as the emulsion had to be precipitated and washed, the use of absolute alcohol was rather costly, so the old-fashioned methylated spirit 64 o.p. was used to make the emulsion in the first place.

The method of preparation was as follows:—352 grains of silver nitrate were dissolved by boiling in 3 drachms of distilled water, and sufficient strong solution of ammonia cautiously added till a perfectly clear solution was obtained. To this solution was added 2 ounces of methylated spirit, and the whole allowed to cool, and then added to 9 ounces of collodion, made by dissolving 175 grains of celloidin in 9 ounces of methylated alcohol and ether. The addition of the silver causes a slight cloudiness, partly due to separation of the celloidin and partly to some of the silver being thrown out; but, if the mixture is well shaken, it clears up somewhat.

The bromising solution is made by dissolving 244 grains of ammonium bromide in 3 drachms of water and 6 drachms of methylated alcohol by the aid of heat, and, whilst still warm, this is added to the silver and collodion in four or five lots, shaking between each addition. When all has been added, the bottle should be shaken well for at least ten minutes, and then distilled water should be added, in small quantities at a time, shaking between each addition, till the whole of the emulsion has separated out, and this can readily be detected, as, on standing, the emulsion collects together, leaving the clear liquid. The emulsion is now poured on to a double thickness of nainsook, the ends of the same collected in a bag, and tied together round a stick, and suspended in a beaker of distilled water to wash, the water being changed three times in fifteen minutes. It should then be allowed to drain well, and gently squeezed, to free it as much as possible from water, and then dipped into methylated alcohol three times, to still further remove the water, and then either well squeezed, or, as I prefer to, sling the bag at arm's length, and thus get rid as much as possible of the spirit.

The emulsion must not be completely dried, but whilst still damp dissolved in a pint of alcohol and ether, this time absolute alcohol being used to dissolve it. To the solution should be added four and a half grains of narcotine, and the whole allowed to stand at least a week to ripen, shaking it frequently.

To sensitise this for colours is a simple matter, although it takes a little time to prepare the solution; but, having once prepared it, or rather the silver eoside, it may be kept indefinitely in the dark. 10 grains of eosine G should be dissolved in ¾ ounce of boiling water, and to this added 5 grains of silver nitrate dissolved in 1 drachm of water. Allow the precipitate to settle, filter, and wash the filter with boiling water till the washing water is strongly coloured, and then with alcohol, and dry in the dark. Collect the dry silver eoside, and keep in the dark.

The sensitising solution is prepared by dissolving 20 grains of the dry silver eoside in 2½ ounces of absolute alcohol to which ammonia is added. The best way to do this is to heat the mixture of alcohol and eoside, and drop the ammonia in very gradually, when the eoside will dissolve; then add 10 ounces of alcohol and sufficient glacial acetic acid to neutralise any free ammonia. The acid must be added cautiously. Two ounces of this dye solution should be added to every pint of collodion, and this quantity of alcohol should be omitted.

The coloured emulsion should be well shaken, then allowed to rest for about five minutes, and then the plates coated and dried at a temperature of 15°C. Hübl recommends their being, when dry, heated for some minutes to a temperature of 30°C., and this, apparently, about doubles the sensitiveness; but, so far as my work is concerned, I have found that, without this supplementary heating, the plates are very little, if any, slower than ordinary wet collodion, and, when using them with a fairly deep yellow screen, the colour rendering is decidedly satisfactory.

The best developer for these plates is glycin, and the formula I use is the following:—

A.

Glycin	½ ounce.
Sodium sulphite	1¼ ounces.
Water	10 „

B.

Potassium carbonate	2½ ounces.
Water	10 „

For use, mix in equal parts. Unless in cases of over-exposure, no bromide is necessary.

After fixation—and I prefer for this the much-decried hypo—the negative should be well washed and dried, and, if necessary, reduced to clear up the dots, and for this I prefer ferridcyanide and hypo; but possibly this may be due to the fact that cyanide in any form always affects my head.

For intensification, I have entirely abandoned pyro and silver, preferring metol, as it gives a cleaner image. The metol intensifier is, of course, much on the same lines as the old pyro, in two solutions:—

Metol	15 grains.
Citric acid	10 „
Water	2 ounces.

The negative is first flooded with this till the film is thoroughly saturated, and then the metol solution poured off and one-tenth of its volume of ten per cent. silver nitrate solution added, and the whole returned to the plate and allowed to act till the desired intensity is obtained.

The above process may seem troublesome, but it is really very easy, and the negatives are all that can be desired, and are quick printers.

A. D. Pretzl.

A COMPARISON OF ORTHOCHROMATIC WITH ORDINARY PLATES.

II.

Writing, as explained in my former article, for the ordinary photographer rather than for the experimentalist or specialist, I shall, as far as possible, keep clear of such side issues as do not seem to bear somewhat directly upon ordinary work. In this I am in the main following Mr. White.

One of the strongest points bearing upon practical photography which Mr. White's experiments seem to emphasise is the comparative inutility of employing isochromatic plates unless a long exposure and dense screen are employed. Pairs of exposures were made upon a colour chart (which together with representative prints selected from several scores of negatives specially made by Mr. White have been left for inspection at the office of this paper) by means of ordinary plates and colour-sensitive ones respectively. Before me are results of one, four, and sixteen inches of magnesium wire burnt during three sets of exposures. The resulting renderings of each pair are very much alike, the improvement in colour rendering becoming more pronounced as the exposure was lengthened. The slight divergencies noticeable in the renderings between the two categories of plates indicate that, although neither approached nearer to theoretical perfection much more than the other, the shortcomings were merely different in their character.

Next as to the influence of screens.

Mr. White, in the first instance, tried the following thicknesses of Ilford screens, which he numbered 1 to 5:—

Screen 1	Ilford	No. 1.
„ 2	„	No. 2.
„ 3	„	Nos. 1 and 2.
„ 4	„	Nos. 2 and 2.
„ 5	„	Nos. 2 and 2, Nos. 1 and 1.

Exposing ordinary and orthochromatic three inches of magnesium at *f*-16 with screen 1, the difference between the two is so slight as to be hardly worth mentioning; the undue predominance of blue rays is painfully noticeable in both, whilst neither renders the proper brilliancy of tone due to the lighter yellows and allied tints. Using nine inches of magnesium with screen 2, there is some slight improvement in the blue, but not much. Thirty-six inches of magnesium with screen 3 gives a rendering in which all colours are nearly of identical tone value. One hundred and four inches of magnesium with screen 4 gives a result which is perhaps as near to perfection as any of the series; but, remembering that the normal exposure as usually calculated was equivalent to one inch of magnesium, it will be seen that, even were we to allow that the last conditions were those best calculated to ensure faithful colour rendering, such would be quite outside the range of ordinary photography as practised for profit or pleasure, for neither in the studio nor in the field would the average photographer for a moment entertain the notion of increasing exposure a hundredfold. Hence the foregoing experiments, in so far as they teach anything, would seem, in my opinion, to point to the absolute futility of using colour-corrected dry plates for all ordinary purposes.

Using No. 5 screen and doubling the exposure of the last exhibits phenomena due to over-correction. Signal green forty-eight magnesium, *f*-16, gives a singularly monotonous rendering of colours which, if indicative of how a landscape of colour, or the rose, apricot, and amethyst of a pretty face would come, inclines one to vow never to use this doleful colour filter. Better the lively lies about blue and yellow than such humdrum quaker tones, which would apparently represent the wings of Iris by means of a leaden grey. This last opinion has only references to the picturesque photography of scenery, and so forth, where absolute truth—never as yet possible—is quite secondary in its importance to effect. Any how the green screen, in so far as it exaggerates the darkness of the scarlets, which negatives never render too light, is no nearer truth than no screen at all.

Thus far, Mr. White's investigations lead him to the conclusion that, while no glass screen that he tested interposed between the object and the dry plate is absolutely effective in correcting inaccurate colour rendering, the best result he could obtain needed a double thickness of Ilford screen No. 2, and an exposure about a hundredfold what is required where an ordinary result on an ordinary plate is aimed at.

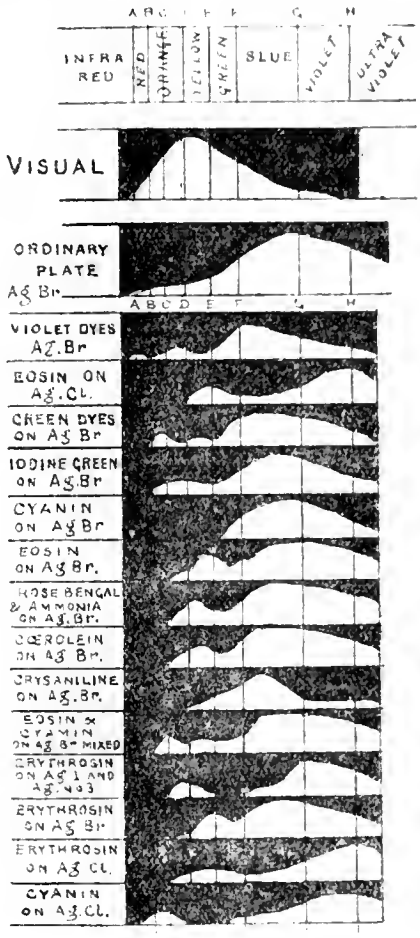
One other point, which is, perhaps, more important to most people than whether a given plate gives fifty or forty-five per cent. of a particular colour brightness in a landscape, or similar subject, is that Mr. White found—what others before have more or less emphatically stated—that the employment of screens—especially dark ones—has a most objectionable lowering effect upon the subject. A dark screen knocks all the brightness, the sparkle, and crispness out of the negative; it seems that whatever is gained in truth of colour is much more than lost by the inadequate light and shadow rendering, and by the flatness of modelling which ensues. The practical man will understand the kind of difference when it is likened to the falling away in brilliancy which happens where a double lens is employed instead of a single landscape lens; only with these dark screens the mischief is much more pronounced.

In looking at the various prints which Mr. White took of his colour chart, one cannot help but be struck by the reiteration of that, as far as I am aware, not fully explained manifestation in virtue of which the photographic effect of colours varies according to their surroundings. Mr. White's chart has, besides a painted kind of spectrum, three strips, which are respectively white, grey, and black; on each of these have been painted four discs, coloured red, yellow, blue, and dark green. The effect of the three different-toned backgrounds upon the rendering of colour values is at times most remarkable; for instance, whereas most of the photographs of the yellow on white show it as palpably darker than blue, the *same prints* show yellow on black as nearly as light as blue, the difference being hardly distinguishable; from which it will appear how fallacious arguments may be which are based upon particular colour charts.*

* See, for example, Mr. Ives's charts in vol. xx. of *Photographic Journal*.

Having taken my readers so far, it will perhaps be as well to proceed a few steps further and bring to their notice a collection of diagrams which Eder, Bothamley, Abney, Vogel, and others, have made to graphically indicate what are the respective amounts of colour sensitiveness in various plates which have been specially treated.

An attentive examination of these diagrams cannot fail to impress upon the observer that with all its faults the ordinary plate is quite as valuable and useful as any single one of the dyed plates represented. The plates thus modified exhibit such a strange, not to say forbidding, erraticism, as would make thoughtful individuals little



inclined to depend upon them. Take that one treated with cyanine; here all light from A to E (that is red, orange, and yellow) is eliminated. Rose Bengal certainly helps to render the due intensity of yellow, but from A to C is quite cut off, while there is a woeful falling away between E and F (green).

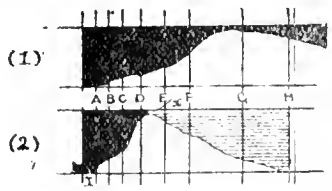
Perhaps most in favour is the mixture of eosine and cyanine, which indicates a tolerably satisfactory scale of sensitiveness. At the same time, although this is particularly sensitive between B and C, the sensitiveness does not extend beyond B to A. Moreover, compared with the ordinary plate, there does not appear to be that great difference from D to E (yellow) which one might expect.

The diagrams, taken as a whole, seem to indicate that, to a large extent, the main action of the different dyes has been *not* to increase defective sensitiveness, but to reduce the redundant action of the too active portions of the spectrum—a result which is, moreover, not infrequently accompanied by the elimination or the diminution of portions of the radiant energy, which we can ill afford to spare.

A reference to the diagrams relating to the visual manifestation of sunlight, and the photographic rendering upon an ordinary photographic plate will indicate why there is much force in Mr. White's contention that, providing full exposure and a dark screen be used, the ordinary plate may be made to record, with quite as much perfection as any other at present known, what are, substantially, the colour values of the spectrum as judged by the average eye.

The visual intensity of light increases rather suddenly from A

to D, whereas the photographic rendering is far too gradual; but, by sufficiently increasing the actinic influence of the light upon the plate instead of the curve being normal it may be represented as by X in diagram 2; one obvious effect of doing this is to very grossly increase the energy of the spectrum from E to H. By interposing a dense screen, as already mentioned, the superfluous light action is, theoretically, reducible until the photographic and visual curves are identical, or nearly so.



Reverting to more practical matters connected with the question, if Mr. White's contention as to the considerable injury caused by the interposition of a dark screen between a view and its image be not over-stated, it is evident that, as at present used, screens are not to be thought of. But with their rejection it by no means follows that correct colouring is in all cases hopeless; for, of course, the objection which is raised to a screen does not hold good with the utilisation of light in which blue and violet is less than usually predominant.

Thus magnesium, gas light, electric lights, and other variously tinted lights, all have their peculiarities, it being perfectly possible, under the most favourable circumstances, by employing a suitable illuminant, to make the visual and photographic effects coincide.

In this usage of artificial light to cut down a considerable proportion of the light energy between E and H, many photographers are inclined to imagine that, roughly speaking, all artificial lights of similar visual appearance have practically the same effect. Such is not the case; hence, and where a specially sensitised or dyed plate is used, the best effect will be obtained when the artificial light is so chosen that it yields a maximum of energy of rays belonging to that part of the spectrum which the plate used is least sensitive to, and proportionately less in the remaining parts of the spectrum.

All who possess a reasonable experience in outdoor photography will know how that Nature at times has a very happy trick of placing a colour screen of her own between one's camera and the scene to be depicted. Such is most often the case towards sundown, but sometimes may occur in broad daylight, when, moveover, there are but faint indications, if any, of such inclination to yellowness of light as we might expect. What is the precise cause of the occasional meteorological manifestations alluded to in the preceding paragraph it is not easy to explain, nor can one always recognise its presence until the negative tells us that the occasion was eminently favourable for the due intensities of half-tones to be accompanied by not over-dense clouds, and other high-lights. In such cases we are specially advised to use orthochromatic or dyed plates; but, if Mr. White's contentions are sound, nothing is needed beyond a slight increase of exposure.

In the application of photography to the copying of such works of art as have colours which have to be translated, Mr. White does not consider dyed plates are called for, except where the colour scheme is unusually pronounced and full of great contrasts. Thus, pictures whose effects are mainly composed of two or three adjacent portions of the spectrum can be as well copied on an ordinary plate as on any other. Where there is any departure from the ordinary plate, it would seem from Table I. that there is much range in the various dyes applicable to the preparation of plates for photographing particular pictures.

Thus, old pictures which are much yellowed by age may be considered as copied behind a screen which greatly over-corrects the original colour values; such a picture usually suffers by the almost complete suppression of blue and other cool tints. To photograph such a work with a plate specially sensitive to yellow (C to E) obviously intensifies the evil, an ordinary plate giving far the better rendering. Probably cyanine on Ag.Cl. (not Ag.Br.) would, however, in such a case as hypothesised yield the best result.

This paper has, I fear, somewhat degenerated into gossip, but is, I hope, not on that account less accurate than many of the dry-as-dust order, which many people either do not care to read or fail to grasp. Those who would wish to become further acquainted with the latest opinions upon the subject will find suggestive matter in a paper by Mr. F. E. Ives, published in *Transactions of the Royal Photographic Society* for April, 1896, and in the report of Captain Abney's lecture in May at the Society of Arts. By the way, Mr. Ives, in speaking of screens, *emphatically* condemns one which has been for years recommended. The screen referred to is the *aurine* one, which Mr. Ives opines is "worse than no screen at all." According to the same authority, great things in colour rendering are possible on ordinary plates, using a combination of chrysoline and brilliant yellow.

From Mr. White's experiments, and other arguments advanced in this communication, it would seem that ordinary plates used with screens may produce results superior to some makes of dyed plates; that it would be very advantageous if plate-makers would mark their boxes of plates with a diagrammatical indication of the plate's relative colour sensitiveness; perhaps not less useful would be the statement as to what dye and other chemicals are used in altering the ordinary range of sensitiveness of the silver emulsion.

HECTOR MACLEAN, F.R.P.S.

FOREIGN NEWS AND NOTES.

Shutters.—We are not surprised to see Dr. Krügner's statements concerning the roller-blind shutter challenged. We summarised them on July 31 in THE BRITISH JOURNAL OF PHOTOGRAPHY. They are now criticised by Hans Schmidt in the *Photographische Mittheilungen*. Dr. Krügner claimed that a slit passing in front of the lens could be quite as efficient as a slit passing in front of the plate; but Hans Schmidt points out that a slit in near proximity to the front of the lens does not transmit a band of light to the plate, as assumed by Dr. Krügner. It merely reduces the amount of light transmitted to the whole plate. For full efficiency, the slit must be some distance in front of the lens; but this has another objection, the farther the slit from the lens, the greater must be its width, otherwise the margins will not be exposed. This necessitates a wider blind, and destroys the advantages of compactness and lightness, which Dr. Krügner claims.

Doubtful Advantages.—The same writer criticises some of the advantages claimed for certain shutters, and recommends the purchaser to be wary in making his choice. One class is recommended because it opens and closes on one side, giving more exposure to the foreground than to the sky; another because it is always ready for use, and the speed can be regulated by pressing the ball—a flattering assumption of the photographer's competence to appreciate the difference between fractions of a second; another recommends his shutter because the image can be seen on the focussing screen in the action of setting. Happily, this hails from Germany.

Requisites in a good Shutter.—The speed, regulated by brake, should be adjustable, always the same, and under absolute control. The release should not be over-complicated, and effected both by hand and pneumatic arrangement. The shutter should move at uniform speed, silently and easily. The arrangement for time exposures should be absolutely certain and not dependent upon artifice; for instance, "pressure and quick release." Easy derangement of the mechanism should be impossible. If these conditions are complied with, the writer thinks the form of shutter unimportant. It will always be ready and certain in action. For the best work the most favourable position is between the lenses, as it obviates distortion and favours rapidity of action.

Movable Studios. — In the *Photographisches Wochenblatt*, M. Barlet offers some remarks on this subject well worthy of attention. The writer thinks we are often disposed to give too much weight to custom. In starting a new business there are many risks, and a portable studio would mitigate the loss if the site proved to be unfortunate. The art of building has advanced so considerably in recent years and materials have been so much improved, that there should be few difficulties in planning a studio combining portability with taste and comfort. Heating arrangements might be greatly assisted by covering the walls in linoleum, and this material may be used with advantage as a floor covering. The writer recommends a paved and cemented floor, which would give a firm foundation for the superstructure. With modern glazing there should be no more difficulty in constructing the roof than in the case of a permanent studio. Makeshift arrangements are not synonymous with failure, and, in confirmation, the writer refers to a series of photographs that

appeared in Germany during the last decade. They excited universal admiration, and two or three photographers of note travelled to a remote bathing place to see the studio where these pictures had been taken. They found a harbour with two high windows. The light was regulated by means of a couple of curtains, and these, with a light background and a reflector, were the only appliances used to produce some really wonderful effects. And the artist? An assuming, amiable, young man, not far out of his teens, but with a quick eye and ready perception of light and shade. He posed with facility, arranged the lighting with the simple means at command, and astonished every one with the dazzling results.

Photo-mechanical Dry Plates.—Liesegang, in the *Photographische Archiv*, points out that fog is usually of the red kind when met with in these plates. They are prepared with an unripened emulsion, and, as red fog is only produced in the presence of soluble silver salts, one of the causes may be a residuum of nitrate of silver. Excess of ammonia in the developer, hyposulphite of soda used as an accelerator, and imperfect washing between development and fixing may also originate the trouble. Grey fog, on the other hand, occurs when an emulsion is over-ripened, over-exposed, or over-developed. It may protect a plate from red fog, but the photo-mechanical emulsion, being unripened and used for line work, where clear shadows are essential, the conditions are more favourable for the appearance of the red variety; but "red fog" is a misleading appellation. When the plate is fixed and washed, the shadows present a faint yellowish appearance. This changes to red in drying. Liesegang formerly thought light was the cause of this change of colour, but now considers it solely due to drying. If the plate is again wetted, the colour is changed to yellow. Red fog may be removed with Farmer's reducer, or bromide of copper, followed by hyposulphite of soda. It will also disappear if the plate is left for a few hours in the fixing bath.

Sunday Rest.—In the *Kölnische Zeitung* reference is made to the laws promulgated in various parts of the Prussian monarchy prohibiting the exposure of goods in shop windows during Divine service. A certain photographer was convicted of having exposed photographs in a show-case, and appealed against the conviction on the ground that the photographs were not exposed for sale, and should not be looked upon as goods. His appeal was disallowed, the Court holding that goods comprised not only objects for sale, but samples used as specimens.

The Kinetograph.—We read, in the *Photographische Correspondenz*, that the firm of Lechner has perfected an apparatus for photographing objects in motion, and reproducing them as lantern pictures. It is called the "kinetograph," to distinguish it from Lumière's kinematograph. It is claimed that the kinetograph is an improvement, as it permits of thirty to thirty-five exposures per second, the pictures being capable of projection on the screen with equal rapidity. The apparatus was exhibited, on July 15, before a number of persons interested in photography and many representatives of the press. Amongst the pictures shown were moving scenes of the Moscow Coronation Procession, street scenes in Moscow and Vienna, scene in the Vienna Riding School, Exercise of the Vienna Fire Brigade, a Skirt Dancer. The last picture was coloured, and very effective, the rapidity with which the series passed through the apparatus hiding any technical defects in the colouring.

Ceramic Photography.—In *Eder's Jahrbuch*, F. Haberditzl, of Vienna, gives the following directions, based on his own experience. The selection of a suitable gelatine is important, the writer having made some 400 experiments before hitting upon the right sort and correct proportions:—Dissolve 7 grammes of hard gelatine in 100 grammes of water, adding 6 grammes of sugar. Take 8 grammes of black oxide, or iridium oxide, rub it well down on a glass palette of about 40 cm. area with about 50 grammes of water, until the latter is almost evaporated. The solution of gelatine is then added a little at a time, and rubbed up with the oxide until a half-set jelly is formed. The mixture is then transferred to a porcelain evaporating dish, and placed in warm water until dissolved. It is then filtered through clean flannel and allowed to set. After a few hours it is redissolved slowly, plates are cleaned with whitening, and a levelling table prepared with a large sheet of plate glass, sufficient to take thirty plates 9 × 12 cm., for which this quantity of solution should suffice. The plates are coated and allowed to set on the bevelled glass. They are then set up to dry in a temperature of about 15° R. for twenty-four hours. When dry, the plates may be kept several months. They are sensitised in a three per cent. solution of bichromate of potash, and dried in a cool, dark place. Printing takes twenty-five to thirty minutes in a medium light, but this can only be determined by experience. When printed, coat the plate with a two per cent. plain collodion, cut round the edges with a penknife, and, immerse in cold water. When the bichromate is removed, lay a sheet of white paper on the film, add a little warm water, and, when the film begins to lift, strip it from the plate and develop with a spray of warm water. Transfer to a five per cent. alum bath for five minutes, and fix with alcohol. The film must then be transferred at once to the final support. When dry, the collodion film, now on the surface, must be removed by gently rubbing with a wad and acetic ether. The picture is then burnt in.

McDONOUGH'S IMPROVEMENTS IN PHOTOGRAPHIC COLOURED SCREENS.

Mr. McDonough says: "The object of my invention is to make a new and improved adjustable regulating screen for use with a camera in taking photographs, by which the quantity of the different coloured rays of light which pass from the object to be photographed to the sensitive plate may be regulated in relation to each other, determinate upon the nature of the light existing at the time the photograph is taken. While it is intended for use in taking all kinds of photographs, it is more particularly intended by me for use in taking photographs in colours

"My improved screen may be placed either before or behind the lens of the camera; or, if preferred, it may be placed in a slot between the two glasses constituting the lens. It places in the hands of a photographer means by which he can regulate the colour values of different light passing from the object to be photographed to the negative plate

"Sensitive plates used in taking photographs differ in their actioic properties in accordance with different sensitising processes. With most sensitive plates the more refrangible rays, such as violets and blues, act very rapidly, and the less refrangible rays, such as reds and yellows, act very slowly. In fact, the ratios vary to a large extent. It is also well understood, as a fact, that in different localities there are more or less alterations of the actinic values in light. Pure sunlight, for example, is different from subdued light or artificial light. On a bright, sunny day the red and yellow colours in the light are in larger proportions than on cloudy days, while the blue and violet colours are in smaller proportions. If we look, for example, at a landscape on a dull day through a piece of orange or yellow-coloured glass, which suppresses the blue rays, the landscape will appear to be illuminated with sunshine, thus showing that there is an excess of red and yellow light on a bright day. Different parts of the sky are differently illuminated, the position of the sun altering the values of the colours. Accepting vermilion red, emerald green and ultramarine blue as representing the three fundamental colours of light, it is important to provide means for altering the amount or value of each separate colour that falls upon the negative plate after its passage from the object to be photographed."

The method of making the screens is fully described. The claims are:—

1. The method of making a negative by regulating the quantity of blue and green rays of light that pass from an object to be photographed to the sensitive plate, which consists in adjusting the size of the openings through which they pass to the sensitive plate, in relation to each other, determinate upon the nature of the light existing at the time the photograph is taken.

2. A compound regulating screen composed of two or more transparent plates uniformly tinted with different tints or colours, and adapted to be placed near the lens of a photographic camera, whereby the rays of light from an object to be photographed pass through such screen before reaching the sensitive plate.

3. A compound regulating screen composed of two or more transparent plates uniformly tinted with different tints or colours, arranged nearly in the same plane and adapted to be placed near the lens of a camera, whereby the rays of light from an object to be photographed pass through such screen before reaching the sensitive plate.

4. A compound regulating screen composed of two or more transparent plates uniformly covered with different tints or colours, arranged in

nearly the same plane, so as to be movable in relation to each other, and adapted to be placed near the lens of a camera, whereby the rays of light from an object to be photographed pass through such screen before reaching the sensitive plate.

5. A compound regulating screen composed of two or more transparent plates of different tints or colours, arranged to be movable in relation to each other, and adapted to be placed near the lens of a camera, combined with means for adjusting the plates in relation to each other, whereby the area of each colour may be easily adjusted to different conditions of light.

6. A compound regulating screen composed of two or more transparent plates of different tints or colours, arranged to be movable in relation to each other, and adapted to be placed near the lens of a camera, combined with indicating scales and means for adjusting the area of the different colours in relation to each other, whereby they may be easily and certainly adjusted to different conditions of light.

7. A compound regulating screen composed of two or more transparent plates of different tints or colours, adapted to be placed near the lens of a photographic camera, and having the part of the screen for regulating the quantity of the red and green rays surrounding the margin of the lens opening, and the part permitting the passage of the blue rays over the centre of the lens opening, and the part permitting the passage of the green rays and regulating the passage of the blue rays intermediate between the margin and the centre.

CITY AND GUILDS OF LONDON INSTITUTE: EXAMINATION IN PHOTOGRAPHY.

We append particulars, taken from the official programme of Technological Examinations, published by Messrs. Whittaker & Co., Paternoster-square, of the Examinations in Photography to be held next May by the City and Guilds of London Institute:—

Ordinary Grade.

I. *Syllabus.*—(1) *The Practical Examination* will include the following tests: To focus, expose, and develop a negative of a person or landscape, to print, tone, fix, and mount an ordinary print.

The candidate may elect to make his negative in collodion or gelatine, and his print may be produced by any of the methods in ordinary use. He will also be allowed to supply, if he so desire, his own apparatus, chemicals, &c., or he may use those provided by the local examiner. The fee for the Practical Examination only will be two shillings and sixpence.

II.—*The Written Examination* will include questions founded on such subjects as the following:—

1. The elements of photographic optics; the photographic camera and its adjuncts, lenses, diaphragms, shutters, shades, &c.
2. A general knowledge of the practice and theory of the wet-plate process.
3. The practice and theory of the gelatine dry-plate process; the composition of and defects in gelatine dry plates.
4. Various methods of fixing, developing, intensifying, and reducing negatives, with a general knowledge of the chemicals employed.
5. Silver printing, including vignetting and printing in clouds, toning, and fixing.
6. Retouching and spotting; mounting prints.
7. The lighting of the dark room.
8. The studio, and lighting of the sitter.

The fee for the Written Examination is one shilling.

Honours Grade.

Candidates for Honours must have previously passed in the Ordinary Grade.

The Honours Examination is both Written and Practical, and consists of two sections: A. Pure Photography; B. Photo-mechanical Processes.

Candidates will be examined in one only of these two sections, and may select the particular branch of practical work in which they desire to be examined.

In order that candidates may know what apparatus and material they will be required to provide for the practical part of the examination, full information as to the practical tests may be obtained from the Examiner on the afternoon of Friday, May 7, for the examination to be held on the following day.

For the year 1897, Practical Examinations will be held in London only, unless ten candidates, at least, apply to be examined in the same section (A or B) at some other centre.

The fee for the Honours Examination (Written and Practical), in either section, is three shillings and sixpence.

Section A.—Pure Photography.

I. *Written Examination.*—Candidates will be expected to answer more difficult questions in some of the subjects for the Ordinary Grade, and, in addition, a knowledge will be required of—

1. The theory of the photographic image, of development, fixing, intensification, and reduction.
2. The theory of light as applied to photography, including a general knowledge of spectrum and orthochromatic photography.
3. The principles of photographic optics.
4. The theory and practical use of sensitometers for testing the speed and gradation of plates, and their uses in printing processes.
5. The general principles of various negative processes which have been employed at different times.
6. Platinotype, carbon, and pigment printing, printing on argentic bromide papers; enamels.
7. Enlarging and making lantern slides in the camera.
8. Applications of photography to scientific purposes.

II. *Practical Examination.*—Candidates may be examined in (*a*) Studio work, (*b*) Copying or Reproduction, or (*c*) Landscape or Architecture. They will be required to show proficiency in conducting any of the following practical operations appertaining to the branch selected:—

1. To take in a studio quarter-plate gelatine negative of some object to be indicated.
2. To take an artistic portrait.
3. To print, tone, fix, and mount a silver, platinotype, or carbon print.
4. To test a sample of glass or fabric to be used in lighting the dark room.
5. To test the sensitiveness and gradation of a plate.
6. To find the focus of a lens either corrected or uncorrected.
7. To copy an engraving for a lithographic transfer.
8. To make an enlargement from quarter-plate.
9. To make a lantern-slide by contact.
10. To make in the camera a lantern-slide from a negative.

The Practical Examination will be held on Saturday, May 8, between 1.30 and 7, and at other times, if found necessary.

Section B.—Photo-mechanical Processes.

I. *Written Examination.*—Candidates will be expected to answer more difficult questions in some of the subjects of the Ordinary Grade, and, in addition, a knowledge will be required of—

1. The theory and practical use of different kinds of sensitometers.
2. The processes of photogravure.
3. The processes of producing 'phototype' blocks.
4. The processes of photo-lithography and photo-zincography.
5. The processes of collotype (collographic) printing.

II. *Practical Examination.*—Candidates may be required to show proficiency in practical operations in one of the above processes, numbered 2, 3, 4, 5, including the preparation of negatives suitable for each class of work, from (*a*) pictures in colour, (*b*) drawings in monochrome, (*c*) originals in black and in tints, and (*d*) natural objects.

The Practical Examination will be held on Saturday, May 8, between 1.30 and 7, and at other times if found necessary.

The Written Examinations in the Ordinary and Honours Grades will be held on Tuesday, May 4, from 7 to 10.

A separate return of the exact number of candidates who will present themselves in each grade, and in each section and branch of the Honours Grade, must be forwarded to the Institute by March 29th.

The following are the questions that were put to candidates at the examination held last May:—

Ordinary Grade.

[*Seven questions only to be answered.*]

1. How would you ascertain whether a lens had a visual as well as a chemical focus? (40 marks.)
2. How would you make or extemporise a background to suit a special effect? (40.)
3. How would you proceed to test a dark room to see whether the light were safe or not? (40.)
4. How would you pose a family group consisting, say, of father and mother, and three boys and two girls, of ages ranging from seven to seventeen? (40.)
5. Give a formula for a combined toning and fixing bath, and compare its merits with those of the separate bath system. (40.)
6. Why does a lens which covers a 10 in. by 8 in. plate, placed either way in the camera, not necessarily cover a plate 10 in. square? (40.)
7. Describe a method of writing titles on negatives so that they will print out on the proofs. (40.)
8. Describe a good and simple arrangement of studio blinds. (40.)
9. Give a design of a simple enlarging apparatus for use with daylight. (40.)
10. Describe the "double transfer" method of carbon printing. (40.)

Honours Grade.

Section A.—Pure Photography.

[*Six questions only to be answered.*]

1. Describe the "Artigue" process of carbon printing. (50 marks.)
2. Describe the composition and manufacture of celluloid as used as a support for gelatine emulsions. (45.)
3. Describe the relative merits of the collodio-chloride and gelatino-chloride printing-out processes. (45.)
4. Describe a simple method of recovering residues from the hypo waste tub. (50.)
5. How would you find out the longest exposure you could give, without showing movement on the negative, to a train passing at a rate of

forty miles an hour in front of your camera, and at a distance of thirty yards from it, it being assumed that your lens has a focal length of six in.? (45.)

6. Discuss the relative advantages of lenses of large and small diameter, both being assumed to be of the same focal length, and to be worked with stops of the same size. (50.)

7. Explain the causes of the phenomenon known as "reversal of the image." (45.)

8. Describe Ives's method of producing stereoscopic pictures in their natural colours. (50.)

9. Describe the process of producing burnt-in enamels on porcelain (photo-ceramics). (50.)

SECTION B.—PHOTO-MECHANICAL PROCESSES.

[*Eight questions only to be answered.*]

1. Give a detailed description of the making of the transparency and preparation of the copper for a photogravure plate. (30 marks.)

2. Describe the operations of sensitising the carbon tissue (with formula for sensitising) and preparing the grain and resist for a plate by the "Klic" or carbon-tissue process. (40.)

3. State what acids, and of what strength, are used for the etching of a photogravure plate, and give, approximately, the normal time necessary for each etching in each solution. (40.)

4. How should a photogravure plate be inked up and printed from, and to what treatment should the printing paper be subjected before use? (30.)

5. Describe (*a*) the operations of preparing a negative by the collodion process of drawing in line for a photographic zinc block; (*b*) of a collodion negative of a photograph or drawing-in wash for a half-tone block. (50.)

6. Give formulæ for intensifying, clearing, and fixing negatives for half-tone blocks. (30.)

7. What is the object of employing irregular-shaped diaphragms or stops in the making of half-tone negatives? (50.)

8. Describe (*a*) the methods of printing on zinc by the bitumen and albumen processes, and (*b*) the enameline process on zinc and copper, and give formulæ. (50.)

9. Describe briefly (*a*) the process of etching a zinc line block; (*b*) the process of etching a half-tone block on copper, giving the kinds and strengths of acids employed. (40.)

10. What kind of a negative is required for the production of a photo-lithographic transfer? (20.)

11. Describe fully the method of preparing and sensitising the paper for a photo-lithographic transfer, and detail the operations of inking up and transferring to stone or zinc. (50.)

12. Give a formula and method of working for the production of a grained transfer from a half-tone subject, say, a photograph or wash drawing. (50.)

13. Describe generally the operations of preparing, coating, and drying a collotype plate, and give formulæ. (50.)

14. Describe the methods of determining the proper exposure of the plate under a negative, and briefly explain the operations necessary for proving and printing from the plate. (30.)

15. State in which instances it would be preferable to employ bichromate of potash instead of bichromate of ammonia for sensitising, and *vice versâ*. (40.)

HONOURS GRADE.

PRACTICAL EXAMINATION.

Saturday, May 9, 1.30 *p.m.*

SECTION A.—PURE PHOTOGRAPHY.

[Only *one* test to be made.]

A. *Studio Work*.—1. Take a portrait bust suitable for vignetting.

Three plates, quarter size, are supplied, and two are to be sent in, but the candidate must select himself which one he considers the more successful.

A rough print should, if possible, accompany the negative. The exposure must be made in the presence of the Local Examiner, but the plates may be developed at home, the results being handed in or posted on Monday.

B.—Copying or Reproduction.—1. Print and develop a print from a negative (supplied by the Institute) by the single transfer carbon process; or 2, Produce a print in platinotype (cold-bath process) from the negative provided for the purpose. The Institute will provide the tissue or the platinotype paper, but the centres or candidates must provide frames, dishes, water, &c., with the exception of the platinotype developer, which will be provided the same time as the paper.

C.—Landscape and Architecture.—Expose and develop a negative of the place or building selected by the Local Examiner.

Candidates are to supply their own apparatus and plates, four in number, each of which must be initialled before use by the Local Examiner.

Arrangements will be made with the Local Examiner by which candidates may have their plates initialled and the site to be photographed communicated to them on the evening of the day prior to the Examination, so that they may have the whole day at their disposal for selecting the most suitable conditions of lighting.

The candidates may develop their plates where they like, but must return all four, used or unused, indicating that one they select as best, to the Local Examiner not later than noon on Monday, May 11, to be forwarded to the offices of the Institute.

If possible, a print should accompany the selected negative, which should be trimmed to the size considered most appropriate, and, in any case, the negative should have the dimensions the print is to have marked on it.

HONOURS GRADE.

PRACTICAL EXAMINATION.

Saturday, May 9, 1.30 *p.m.*

SECTION B.—PHOTO-MECHANICAL PROCESSES.

[Only *one* test to be made.]

(*a*) *Photogravure.*—1. Prepare a transparency from a negative by a carbon process for photogravure. (30 marks.)

2. Print a "resist" from a transparency, and transfer and develop on copper prepared for etching. (50.)

(*b*) *Phototype Block.*—1. Print from a line negative by the albumen process on zinc, and prepare the plate for retouching before etching. (30.)

2. Print from a half-tone negative on zinc or copper by the enameline process, and etch the plate. (50.)

(*c*) *Photo-lithography.*—Print a transfer from a line negative, and ink up ready for transferring to stone. (50.)

(*d*) *Collotype.*—Prepare sensitised solution and coat a glass plate, dry same, expose under a negative, and make ready for printing. (50.)

THE JOLY PROCESS OF COLOUR PHOTOGRAPHY.

[American Philosophical Society.]

I HAVE the honour to present to your notice this evening, by courtesy of Mr. Richard Barkley, of New York, a series of specimens illustrating the so-called "Joly" process of colour photography.

They are the same as were lately shown before the Royal Society of England, and excited considerable attention.

This process, although it depends upon the three primary colour sensations, differs materially from all others thus far brought to the notice of the public, because but a single photographic manipulation is required, and no apparatus is needed other than such as is used in ordinary every-day photography.

This process consists in making a negative through a closely lined screen, ruled in three colours, viz., orange, yellow-green, and blue-violet. The screens used in the specimens here shown were made with an ordinary ruling pen, such as is used by draughtsmen, and the lines number about 200 to the inch. A finer ruling in the future will make the lines which we now see in the specimens before us less prominent.

It will be noticed that Professor Joly, in his "taking" screen, which is here before you, has substituted for the usually accepted primary colour sensations—red, green, blue—the colours, orange, yellow-green, and blue-violet. Experience has taught him that not only were the former colours unsuitable for the purpose, but that, to reproduce the effect of natural colours, a somewhat different screen must be used over the resultant positive image. For this purpose Professor Joly rules a screen in pure red, green, and blue-violet. This he calls his viewing screen.

[For the red-selecting lines of the "taking" screen Professor Joly uses a spectrum colour, such as that to be found at one-sixth of the distance from the line D to the line C; for the green-selecting lines he uses a colour corresponding to that of the spectrum at about one-third of the distance from the E line to the D line; and for the blue-violet selecting lines he uses a colour corresponding to the spectrum colour near the F line, but toward the G line. On comparison of the "taking" screen with the spectrum, these colours can be called a red-orange, yellow-green, and a violet-blue. For the colours of the "viewing" screen he uses a pure red not far from the C line; a green near the E line; and, for the blue-violet lines, he takes a spectrum colour between G and H, the object being in the "viewing" screen to transmit fundamental colour sensations only, and to let the eye do its own mixing; the eye is assisted by the depth of light and shade in the linear areas of the positive; for instance, if the full amount of light of two adjacent red and green lines be transmitted, the eye sees a yellow; if, now, some of the green be obstructed or shut out by the positive over it, then the eye will see an orange; and, if, on the other hand, some red be shut out by the positive, then the eye sees a yellow-green, and it is easy to see that one can run all the colours from pure red to pure green by the varying amounts of the red or green lines shut out by the positive.]

The first specimen we have here is a negative of a china plate and jug, photographed through the "taking" screen.

The next one is a glass positive printed in contact from the above negative. It will be noticed that neither of these specimens differ from ordinary photographic results, except that lines due to the use of the screen are somewhat prominent.

The third specimen is a positive similar to the one just shown, placed in register with a "viewing" screen; and, by holding it up to the light and viewing it through the ruled grating, we see the china plate and jug in the bright colours of the original objects.

The next subject is a male portrait from life. This illustrates the possibility of the process in its application to professional portraiture.

We now have a portrait of an Irish peasant girl, not from life, it is true, but from a water colour, which is here before us. The specimen labelled No. 7 is placed in contact with a viewing screen. The original is here offered for comparison, so that you may judge of the fidelity of the reproduction to the colours of the original. To prove the correctness of his theory, Professor Joly here presents another specimen of the same subject, No. 12. This is taken and placed in contact with the same ("taking") screen. The great difference and the falsity of the colour rendering will at once be noted by comparison with the original.

The next specimen is perhaps the most interesting one of all, on account of being an almost instantaneous picture.* It represents a military band in the Park of Trinity College, Dublin. It will be noted that the bright reds of the uniform coats are exceptionally well rendered. Further, this example indicates a possible application of this method of colour reproduction to snap-shot photography.

I now wish to call your attention to an interesting feature of this process, viz., the necessity for having the photograph and screen in exact register, and viewing it in a normal position. Viewed direct, this transparency shows the colours of nature; the brilliant red hue of the coats is especially noticeable. Now, if we turn the transparency so as to view it at a slight angle, we at once note a change of the colours, and, in this particular instance, an apparent change of the nationality of the subjects: in place of English soldiers in bright red coats, we see a body of men dressed in brilliant green; in short, the Englishman appears to have been turned into an Irishman of the most pronounced type.

The next subject is a perfect representation of a green fluorescent bowl, made of uranium glass.

We now come to another interesting specimen—a photograph of a bunch of wall flowers, executed in two colour sensations only, viz., the red and green sensations. This picture derives an additional interest from the fact that it was made by Professor Joly, at the request of Lord Kelvin, to show the effect of "violet blindness," an extremely rare variety of colour blindness.

I now present to your notice two photographs of the solar spectrum from nature, the first one made through a "taking" screen, and seen through a "viewing" screen, which, as you will perceive, shows some of the principal lines; the other one, both taken and viewed through the "viewing" screen, shows a false colour rendition. The yellow, passing through the red lines only, is almost entirely represented by pure red. The incorrectness of the result is evident on comparing it with the first specimen or with nature.

I now come to the commercial part of the process. I have here for your inspection a specimen of three-colour printing. The original photograph consists of a single negative; the printing was done from three separate half-tone blocks or plates—red, yellow, and blue.

This result is obtained by making three positives in the camera from the original negative in the following manner:—A special screen is prepared, with black lines twice the width of those upon the taking screen, the intervening space being the width of a single line. This screen, when placed in register with the original negative, it will be observed, exposes only every third line of the negative. Now, it will be obvious that, if this screen be moved the width of a single line before each exposure, we shall obtain three positives, each showing but one-third of the original negative, and, at the same time, representing a different colour sensation. An ordinary half-tone plate is now made from each positive in the usual manner, and then printed successively in yellow, red, and blue inks, the same as in the ordinary chromo-typographic or three-colour process.

In the case under consideration, you will note the almost perfect result without the presence of the objectionable mathematical cross-line hatch-work.

The latter adaptation of the Joly process, I am informed, is the invention of two young men in this country, and, should it prove practical and give certain results, it will, without doubt, be a great step forward in chromo-typography, and also have commercial value.

It is a curious fact that the foundations of the interesting processes I have described are based, and depend for their ultimate success, upon the ruling machine, an invention of Joseph Saxton, a former member of this Society, specimens of whose early photo-mechanical reproductions, made in 1841, are still in our possession.

In conclusion, I will state that the one great advantage which this process seems to offer over other schemes in heliochromy or the three-colour process, is the fact that but a single negative is required, which is obtained by the ordinary method of photography, so that all special or intricate apparatus, with uncertain results, are obviated. It will be further noted that the specimens shown here to-night are among the earliest ones made with crude appliances as to the ruling of the screens and the pigments. JULIUS F. SACHSE.

* Actual time about three seconds.

SOLARISATION OF DRY PLATES.

THE *Photographisches Archiv* for May 1896, page 129, contains an article from the pen of R. Ed. Liesegang on the "Solarisation of Dry Plates." A translation of this appears in THE BRITISH JOURNAL OF PHOTOGRAPHY for June 12, 1896, p. 376.

In this article Liesegang commences by drawing attention to the positive which is seen when a negative is viewed from the back against a dark background. He points out that these positives are less pronounced in the case of under-exposed negatives, but distinct and of a whitish colour in the densest portions (such as the sky of a landscape), of fully exposed negatives. He then proceeds to make the following positive and decidedly startling assertions, that "this whiteness is due to a remnant of bromide of silver, which is left unchanged during fixation, and is held between the reduced silver and the glass. . . . . In those parts of the plate fixation is not complete, and, even if more time had been given for the action of the hyposulphite of soda, the bromide of silver would not have been removed. . . . If bromide of silver is left behind amongst the silver, the former cannot have been reduced by the developer, and the picture does not always extend from the surface to the glass. And especially is this the case in the highest lights, where it might be most expected . . . . *It is therefore certain that the developer also has not penetrated to this depth in the high lights* (the italics are his own) and therein resembles the hyposulphite of soda. With a shorter exposure, on the contrary, it penetrates the entire film and reduces the bromide of silver through to the glass."

In support of the above statements Liesegang brings forward not a single convincing chemical experiment, but only a number of observations which can more simply and correctly be explained according to the usually accepted chemical hypothesis.

Yet, based on these, as I hold, incorrect assertions, Liesegang proceeds to propound a theory of solarisation, which practically amounts to this, that in a negative a more or less dense film of silver is formed on the surface, where strong light has acted, and this film acts as a mechanical restrainer and retards, *or even prevents*, development and fixation of the more deeply seated silver bromide in these fully or over-exposed portions. At the risk, however, of being tedious I had better give his own words:—

"In this way a phenomenon can be accounted for, in explanation of which purely chemical causes have usually been accepted, viz., the solarisation of dry plates.

"If part of a plate is very considerably overexposed, the reduction is confined to the mere surface in that part. The film of metallic silver formed there is extremely thin, but it hinders completely the further penetration of the developer.

"The reduction on the surface is too rapid at that part, but at the others, where the exposure is less, the reduction occurs more slowly, and meanwhile there is time for the developer to penetrate to the underlying portions. The latter consequently are stronger, and contain no bromide of silver.

"The rapidity of reduction is the all-important thing. It is not necessary to assume, as I at first thought, that with longer exposure a coherent skin of silver, whilst, on the contrary, with shorter exposure, one rich in pores is formed."

Curiously enough, after making these very positive assertions, we further on came upon this very convenient admission, "It is impossible to prove or to controvert this theory of solarisation, in the development of dry plates by experiment." Surely, if it is impossible to prove this theory, it is useless to assert it so positively. At the best it can but be looked upon as a working hypothesis.

As a matter of fact, one or two very simple experiments and observations are sufficient to prove the inaccuracy of the statement on which Liesegang bases his theory. These I propose to record here and to discuss some of the various observations he adduces in support of his theory, leaving to a future occasion the discussion of the alternative chemical theory which experiments I now have in hand point to as being an excellent working hypothesis.

1. Place a very fully exposed film negative, which has been developed for four or five minutes, in a fixing bath, and allow it to float face downwards so that the back can be observed as fixing proceeds. It will then be clearly seen, especially if the emulsion is thick enough, that even in the overexposed parts the undeveloped silver bromide next to the celluloid support gradually fixes out.

2. On examining such a negative from the back against a dark background the fully exposed portions, and especially the densest portions, show the whitish appearance that Liesegang puts down as due to unfixed silver bromide. Now proceed to partially strip the gelatine negative from the celluloid support, so that one-half of a high light still adheres to the film and the other half is free. A film negative being more pliable than a glass one, it is easier to properly separate the gelatine from its support. The negative is now reimmersed in the hypo solution, so that the latter has full access to the back of half the high light. After half an hour or an hour's fixing, re-examine the stripped and unstripped halves. It will be found that the two show practically no difference. In other words the whitish appearance at the back of the high lights is not due to silver bromide. If the gelatine is very soft, the free portion of the gelatine skin may swell and stretch a good deal. It will, therefore, look a shade more transparent in the high lights when free than when it adheres to the

support. After many hours too in the hypo solution, a slight darkening at the back will be visible, but it is extremely probable that this is due to the slight solvent action which Messrs. Haddon and Grundy have shown hypo exerts on the fine silver deposit, constituting the image, in the presence of air.

Other experiments can easily be adduced, but practically No. 2, given above, disposes of the whole of Liesegang's hypothesis.

Now, with regard to the observations which Liesegang brings forward in support of his theory; he writes "In the *Photographisches Archiv*, 1996, p. 10, I have drawn attention to the fact, that a dry plate upon which a metallic veil has been formed during development fixes very badly. It always contains a remnant of bromide of silver."

I find, on looking up the original article, that the metallic veil referred to is red fog, which he states forms a difficultly permeable film over the surface of a plate, causing it to fix more slowly and even leaving a faint white deposit (according to Liesegang) of unfixed silver bromide in the gelatine film, visible by reflected light, but almost invisible by transmitted light. Here again, however, he brings forward no valid chemical proof in support of his hypothesis that this faint white deposit is silver bromide. The mere fact that the plates will fix even when red fog is present is surely sufficient to make one suspect that, whatever this white deposit may be, it most probably is *not* silver bromide. Some gelatines when wet show a white opalescence, and again, plates which show marked red fog by transmitted light look greenish-white when examined against a dark background by reflected light. As a matter of fact, however, it seems to me that Liesegang has put the cart before the horse, for thickly coated plates, *i.e.*, plates which fix slowly, are very liable to show a red stain. If a pyro developer has been used, this stain may be due to two causes. First it may be true red fog (*i.e.*, a fine silver deposit) most probably caused in the following way. Owing to the slow rate of diffusion in the thick gelatine film, it is not easy to remove the developer from it; consequently, when the negative is being fixed, the developer left behind may reduce some of the soluble silver thiosulphate salts formed when the fixing solution enters the gelatine, and a fine red deposit of silver is thus left behind in the film. A test-tube experiment will demonstrate the probable correctness of this explanation. To some washed silver bromide add only just sufficient strong fixing solution to dissolve it, then add a little pyro soda developer. On allowing the mixture to stand for a short time, the silver in it will be seen to precipitate in the form of a mirror on the sides of the test tube. Secondly, the stain may be simply pyro stain, for during its slow diffusion out of the thick gelatine film the developer gets oxidised to a red pigment, and subsequent treatment with acid will not entirely destroy this stain; prolonged washing only intensifies it. Treatment with a copper sulphate solution containing potassium bromide, as Liesegang recommends, will remove the red fog, but not the red pyro stain. The best cure for these stains I know of is *prevention* by immersing the films in a strong alum bath slightly acidified with sulphuric acid, or in a ten grain to the ounce chrome alum solution immediately after developing the negatives, only giving them a very short washing or rinsing between the two operations. After remaining in the alum bath for five minutes, wash them slightly and then fix them. They will be free from stain, the staining and developing power of the pyro in the gelatine film having been destroyed. N.B. Not all negatives, however, will stand this treatment, as the great hardening they are subjected to causes them to adhere less firmly to their support, and they then tend to blister off it.

In support of his contention "that the silver reduced by light and the developer does not permit the hyposulphite of soda to force itself through," Liesegang next brings forward this statement: "This explanation is supported by the fact that, at the juncture of a very dark with a light part of the negative, the bromide of silver is removed in fixing for the breadth of about a millimetre round the dark part. Consequently the positive seen from the back of the plate is smaller than the negative. The hyposulphite of soda in those parts has not penetrated from above, but sideways." At first, I confess, this observation seemed to bear our Liesegang's hypothesis; but recent experiments I have carried out show the cause to be a very different one. However, the explanation would take too long here, and I can only, at present, state that the black edging is an halation phenomenon, and that its colour, as well as the colours of the different silver deposits which go to form the image in a photographic film, are entirely dependent on the character and amount of the silver deposit in the different portions of the image.

Finally, Liesegang adduces the following observation, made with gelatino-bromide plates, as a good instance proving his theory: "A normally exposed plate after a certain time shows a negative through the glass (for shortness I will use the expression negative penetration). This negative grows more intense as development proceeds."

"An underexposed plate also shows negative penetration, especially if so much light has passed through that a blackening is perceptible from the glass side, otherwise it remains uncoloured. A much-over-exposed plate, after prolonged development, shows strong positive penetration. Sometimes this positive is preceded by a negative, but this soon disappears as the back takes on a faint even colour. The positive then follows."

Now this very clearly describes what is frequently observed in the case of plates which show a tendency to give chemical fog, particularly when, owing to slow setting, such plates have a layer of coarse and easily fogged particles of silver bromide deposited close to the glass. Now possibly the mechanical *restraining* in the high lights which Liesegang suggests does take place, but I am convinced not to anything like the extent that he imagines. On the chemical hypothesis of development and solarisation the above observation is very simply and thoroughly explained. Where the light action has been greatest, development is at first very energetic on the surface, and therefore in the high lights the penetrating developer not only gets weakened, but also relatively excessively restrained, so that it may happen that the developable particles of silver bromide next to the support in those places will be longer in developing than the corresponding particles in the shadows. Viewed from the back, therefore, the shadows will appear blackish and the half-tone and high lights whitish.

F. KROHN.

The Inquirer.

*** *In this column we from time to time print questions that may be addressed to individual contributors to our pages, or such as are sent to us with the view of eliciting information from a variety of sources. We invite the co-operation of our readers in rendering this feature of the* JOURNAL *useful and instructive.*

CARBON PRINTING.—J. B. inquires: "What is the supposed advantage of the addition of ammonia to the bichromate sensitising bath for carbon tissue? Am I right in supposing it leads to greater sensitiveness? I have been trying it lately, adding one drachm of strong ammonia to a pint of five per cent. bichromate, but the only effect I can trace is that the tissue becomes insoluble in half the time it does without the ammonia."

ENCAUSTIC PASTE.—J. ESCOTT says: "Formulæ are given in the ALMANAC and elsewhere for 'encaustic paste,' which I am told is a preparation to be applied to the surface of prints to give them a better finish and bring out the details. Is it to be used as a preliminary to rolling or burnishing, or does it dispense with the burnisher altogether? Also, is it suitable for gelatine and collodio-chloride paper, or is it only for use with albumen?"

NON-COAGULABLE ALBUMEN.—In reply to E. Freeman, "Beta" and several others say: "In the present year's ALMANAC will be found an article by Mr. Edwin Banks on 'Inverted Albumen,' which I expect is the substance inquired about by your correspondent." We have also made search, and find that the leader in which this peculiar form of albumen was described appeared in our issue for August 15, 1884. In that article and in Mr. Banks's the fullest details of its properties will be found.

TRIPOD STAND "JAMMING."—AMATEUR writes: "I have a folding and sliding tripod which is a source of great trouble to me. If laid away for only a few days the sliding portion becomes so jammed together that it is impossible to move it until it has been held before the fire for some time, and this treatment I am sure cannot be very good for it generally. When it has been in use in the open air for a few hours it works easily and freely enough. Could you inform me of any sort of lubricant I could apply while it is in this condition that would keep it in working order? I have tried French chalk, but that does not seem to do much good. A friend suggests black-lead, but that would be unsightly and dirty."

UTILISING CALOMEL.—W. B. H. writes: "In reply to W. H. E. *re* Calomel, for many years past, when in travelling, I have found that intelligent creature, the country pharmaceutical chemist, disinclined to let me have an ounce of corrosive sublimate, I have invariably fallen back upon calomel. He doesn't mind how I poison myself as long as I don't get him into trouble. It is not much trouble to work it up into intensifying form. Take an ounce of calomel, an ounce of hydrochloric acid, and two or three ounces of water, and boil the whole together in a porcelain dish, or in a jam pot plunged in a saucepan of hot water. The calomel will soon dissolve, forming a strongly acid solution. Allow it to cool partly and add, drop by drop, strong ammonia until a slight permanent precipitate is formed, and the solution should then be neutral or nearly so. It may now be filtered and made up to twenty ounces, and will consist then of the ordinary solution of bichloride of mercury and sal ammoniac given in the text-books. I am not sure that it isn't an easier way to make the solution than by dissolving the bichloride direct, as the latter takes such a lot of shaking."

Utilising Calomel.—In reply to W. H. E., you are wrong in saying hydrochloric acid has no action upon calomel, though at ordinary temperatures it has not much. If you will boil the calomel in an open dish with dilute hydrochloric acid, it will soon dissolve, and, by adding gradually more acid and more calomel until a very concentrated hot solution is obtained, the corrosive sublimate is easily produced in crystals on cooling. Or, by calculation, a solution of definite strength can be made without the trouble of crystallisation. It is important that the operation be carried out in contact with the atmosphere as in an ordinary evaporating basin, as, if done in a close flask, a portion of the mercury is reduced to the metallic state..—F. P.

Insensitive Collodion Emulsion.—Replying to "Halifax," I should say from my own experience that the *best* light that could be safely used for coating as referred to by Mr. E. Sanger Shepherd is such a light as would suffice for wet collodion, but that would not be sufficient after the emulsion plate was washed. It is a curious fact that although less sensitive, in the camera, than wet plates, bromide emulsion films are more *exigeant* in the matter of the illumination permissible in their handling, and would fog badly in a light which would be quite safe for wet collodion. As for coating in daylight, if it were possible, I would reiterate the remark made on Aug. 14. *Cui bono?* In the old days of tents and wet plates there was a very distinct advantage in being able to coat the plates in the open air, when an old and well ripened iodised collodion was in use; but an ordinary collodion emulsion does not possess the pungency or the penetrating powers of such a collodion.—Syntax.

Retouching Medium.—Portraitist asks: "Can you or any brother professional give a formula for a really reliable retouching 'medium?' I have tried several that have been placed on the market, but find them as a rule worse than useless. Sometimes, for no very apparent reason, they behave decently—at least some of them—but I am at a loss to discover the reason of my occasional successes. One very much advertised 'medium' when applied as directed gives a greasy surface, which certainly takes the lead to some extent, but it is so smeary that the negative cannot be printed from for a day or two, and even then seems to attract every particle of dust about the place, to remove which means also removing the retouching. If allowed to harden, which it will do in about a couple of days, before retouching, the pencil refuses to bite at all, so I don't see much use in it. I have done and can rely upon doing better work with a simple solution of common resin or turps, and this has the further advantage that a pint of it does not cost as much as an ounce of the other. I am speaking now of retouching *on the film*; for varnished negatives I want a better surface than that given by the varnish for which the formula is given in the Almanac, consisting of sandarac and castor oil. But it is often desirable to do some of the work before varnishing. *Is* there a trustworthy 'medium?'"

Insensitive Collodion Emulsion.—In reply to "Halifax," it will depend entirely upon the purpose to which the emulsion is to be put whether it may be coated in daylight. If for landscape work, with a full or very long exposure, it is probable that coating in diffused daylight would not do much harm; but, for any purpose where extreme purity of the unexposed parts is necessary, such a course would be fatal. Although unwashed collodion emulsion, and, to a less extent, washed emulsion, are practically unaffected by daylight *in bulk*, the matter is very different when spread on a thin film upon glass. Then the washed emulsion is just as sensitive wet as dry, and the apparent immunity from injurious action before coating is only due to the fact that the fog produced on the surface exposed is mixed up with the body of the emulsion and masked. But every such exposure detracts from the brightness of the emulsion. With unwashed emulsion the case is somewhat different, owing to the presence of soluble bromide. Here the coated, but unwashed, film is so insensitive that it may be exposed in the camera for a much longer time than actually necessary if washed, and no image will appear on development; but it may be re-exposed and produce a perfect result. For any work, such as transparencies, I doubt whether it would be safe to coat by uncovered candle light; certainly daylight would ruin the brightness of the high lights, although in the case of a landscape negative the veil produced would perhaps be an advantage in the shadows. I am speaking now of ordinary emulsion, but, if it be colour-sensitised, it requires nearly as careful handling as gelatine plates.—W. B. B.

Fixing Prints.—C. P. R. asks some questions that look very much like conundrums. I should say that the best way of "gauging the sufficiency of the solution" is to have enough to comfortably take the number of prints to be fixed. There is nothing to gain and everything to lose by "scamping" the work or by tempting to economise hypo. Then again, if "just sufficient solution has been used" it would look as if it ought to be *exhausted* at the finish, and that its "strength, in hypo at least, would be *nil*." At any rate, the "hydrometer" has yet to be invented that would prove of much, if any, use in this direction. With the strength of solucion and time of immersion mentioned, C. P. R. need not trouble himself further than to use plenty of it and to turn the prints over singly two or three times, so that they may get a fair share of its action. And then he will save more in the long run by throwing it away than by attempting to do with half the quantity or venturing into specific gravity tests. "Alpha's" queries also relate rather to fixing than washing. The best temperature for the fixing bath is that of the atmosphere at the time, unless it be excessively hot or cold, when artificial means ought to be used to bring all the solutions and washing waters to something near the normal. The strength of the bath will depend upon circumstances to some extent, depth of printing, character of paper, tone desired, &c., but three ounces of hypo to the pint, or a fifteen per cent. solution, as C. P. R. has it, which is nearly the same, is a very good standard, to be varied as circumstances dictate. A weaker solution takes slightly longer to fix, but reduces the prints less, and has less influence in altering the tones. Beyond that, there is not much to choose between two or four ounces to the pint.—Syntax.

Our Editorial Table.

We have received for trial, from Miss Annie Wood, of 33, Great Coram-street, W.C., a small sample of sensitised albumenised paper. It appears to give very good results.

Samples of Christmas Mounts.

Marion & Co., Soho-square, W.

The earliest reminder of the forthcoming festive season comes to us from Messrs. Marion & Co., who send us several samples of mounts for Christmas photographic cards. They are of great variety, and range in size from midget to cabinet, comprising the folding, the single, the embossed, and the "slip-in" kinds, so that there is a choice of either mounting the photographs direct or slipping them in the mounts. The tints selected are artistic and in good taste, and the designs are in all cases refined and pleasing. The list accompanying the samples shows that Messrs. Marion have a most varied selection, from which it should be impossible for the photographer to make a choice without pleasing himself and his customers.

Optique Photographique.

Par Adolphe Miethe, Dr. Sc. Paris: Gauthier-Villars et Fils.

This is a translation, in French, of Dr. Miethe's work, in German, on the optics of photography, a subject with which, it need scarcely be said, the author is well qualified to deal. The book before us avoids mathematics, and is designed to appeal to practical photographers; nevertheless, it appears to be fairly exhaustive. The principal chapters treat of the principles of optics as applied to photographic lenses; aberrations; and diaphragms; while the commoner types of lenses are examined and described, the book concluding with the description of a series of tests for lenses. A chapter is appended briefly telling of the chief points involved in the manufacture of lenses. The work is an admirable one.

Catalogues Received.

C. P. Goerz. Berlin.

Mr. Goerz not only makes the anastigmatic lenses with which his name is associated, but also, according to the evidence of his catalogue which is before us, gives attention to other forms of objectives, as well as cameras, studio, tourist, and hand, the latter in great variety; stands, lanterns, shutters, dark-room requisites, &c. Some optical tables and notes are included in the catalogue, which is well illustrated. We may note, in passing, that special prominence is given to the Anschutz hand camera.

E. Mayo, 8 & 10, Boulevard Mageuta, Paris.

Appealing chiefly to amateur photographers, M. Mayo's catalogue, which consists of about 160 freely illustrated pages, deals with a

very varied assortment of apparatus. Judging by this and the catalogue above noticed, English and Continental photographers possess great similarity of taste, and require to be provided for in just about the same manner.

Artistic Landscape Photography.

By A. H. Wall. Bradford: Percy Lund & Co.

Surely those who aim to produce pictorial results in photography are well catered for as regards books on art. The volume before us is the second on the same subject, from the same publishers, that has reached us during the last few weeks. Mr. Wall addresses beginners in art, "including the veriest tyros," but he is frequently so controversial that he cannot escape going over the heads of his audience. His chapters, which partake largely of the nature of essays, discuss such subjects as, "The Imagination and its Cultivation." "Truthfulness in Art," "The Expression of Space," "Skies, Clouds, and Aerial Perspective," "Water as an Element of Pictorial Effect." There are several explanatory illustrations, and the work which, in our judgment, hardly appeals to a beginner, is well worth reading. We append two extracts, which will give our readers an idea of the lines upon which the book is fashioned.

"The Ordinary Camera Man

". . . . sees what he wants almost at a glance, and straightway plants his tripod at the usual height, elevates his camera, and looks to its levelling, focusses to secure equal sharpness of detail on every plane, near or distant, and in every object, whether of dominant or subordinate interest; regulates his exposure and development with ideas in no way suggested by pictorial intentions, imaginative conceptions, or poetic sentiments. He is in every way the slave of his tools . . . . And, as he seeks a subject, so he exposes a plate with his heart untouched, his thinking powers inactive; . . . . proud to think he can 'take a picture,' and call himself an artist," &c.

"The Artistic Man

". . . . sees the selected view at various times; under different conditions of light and atmosphere, carefully determines what shape and size will be best for it in connexion with the means he has to work with, and all he desires to include in the view, and also what he desires to exclude. He tries various points of view; now higher, now lower; now to this side, now to that; sometimes backward, sometimes forward; his thought all the time busy with the principles of harmony, variety, contrasts, considering the value of time in connexion with the coming exposure and development, and anxious about obtaining truthfully the expression of air and space," &c.

We hesitate to run counter to so high an authority as Mr. A. H. Wall, but we cannot help suggesting that both the above pictures are grievously overdrawn. "Ordinary" camera men are not the fools he tries to make them out, nor are "artistic" camera men the formidable geniuses he would have us believe. And we know a good many of both sorts of photographers.

Early Work in Photography: A Text-book for Beginners.

By W. Ethelbert Henry, C.E. London: Dawbarn & Ward.

The beginner, like the photographer supposed to be pining after art knowledge in camera work, is also liberally catered for, very many first handbooks and primers having been recently published; but Mr. Henry's book disarms objection by its excellence, and is really one of the best and most practical text-books for beginners that we have read. It is a useful and plainly written guide to stand-camera work, full of sound information on printing, toning, developing, &c.: the use of apparatus; work in the dark room, and a score of other subjects. There are many helpful illustrations and an actual negative and positive on celluloid accompany the book, which we can cordially recommend to new hands. We quote the introductory hint to beginners: "If you wish to be an all-round, slip-shod dabbler, try every different make of plate, paper, developer, and toning bath that each of your friends recommends—of course before mastering any of the technical details of photography. But, on the other hand, if you wish to become a clean and careful worker, capable of producing excellent results, stick to one brand of plates, one formula for developer, and one toning bath until you understand them thoroughly and can produce a good negative and a good print every time—or else know the exact cause of failure. When you can do this, the field of experiment is ready to offer you a welcome." It is an old sermon, to be sure; but how true!

The Cadett Plates.

Cadett & Neall, Ashtead.

Sample packets of the latest makes of two of Messrs. Cadett & Neall's popular brands of plates have lately reached us, and were subjected to trial in the camera. These were the Ordinary and the Professional. According to the speed numbers, the Professional is a plate of about three times the rapidity of the Ordinary, the actual H. & D. numbers being 61 and 21 respectively. Using pyro soda, we found this ratio about maintained in practice. The quality of the results yielded by the Ordinary point to its being well adapted for landscape work, interiors, &c., density of deposit and fineness of grain, as claimed, being its characteristics in a marked degree. The Professional—the faster plate—gives soft and delicate results that appear to fit it admirably for portrait and studio work. It has always been our experience of Messrs. Cadett & Neall's plates that scrupulous care appears to be exercised in their preparation, and thus we were not surprised to find the samples of the Ordinary and the Professional clean and flawless. Photographers must take pleasure in using such well-made plates.

News and Notes.

"Invention."—Our interesting contemporary is now under new proprietorship, and Mr. Perry F. Nursey has been appointed Editor. Many new features are promised.

The Photographic Club.—Anderton's Hotel, Fleet-street. The subject for discussion on Wednesday, September 2, will be *The Management of a Photographic Society*. To be introduced by Mr. Walter D. Welford.

"The X Rays in 1847" is the heading of a paragraph which our contemporary, the *Scientific American*, quotes from its number of June 5, 1847, wherein it is stated that "a Belgian *savant* says he has just discovered that electric light directed on the human body makes it so diaphanous as to enable the arteries, veins, and nerves to be seen at work, and their action to be studied."

Royal Cornwall Polytechnic Society's Exhibition.—Awards in Photographic Department: First silver medals—W. M. Warneuke, G. Lafayette, W. J. Byrne. Second silver medals—H. Yeo, W. M. Harrison, E. Bull, Dr. W. Page May. First bronze medals—F. Marsh, W. H. Pugh, S. Bolas & Co., C. M. Wane, F. C. Iuston, H. Tonkin. Hon. mention—Mrs. J. Blamey. Photographic Appliance Department: Messrs. Spratt Brothers, first bronze medal; acetylene apparatus awaiting trial.

Suiting the Action to the Word.—At the recently held Convention in America, Mr. G. G. Rockwood was lecturing, and a question came from the audience concerning the use of head rests. "This," said Mr. Rockwood, "cannot be disposed of by any arbitrary rule. Sometimes we must use them; at others they are impracticable. Let me tell you a story. A dramatic company came to me to be photographed in the principal tableaux and scenes of a play which I had studied and noted with much care. It had been my experience that a recital of the text with the accompanying action and an instantaneous shot would give the desired result. I had been very successful before with the manager of the company, and in this play was especially desirous of surpassing myself. I met an obstacle in the person of the principal character in the play, who was a well-known teacher of elocution and acting. He demurred to my suggestions, and mechanically placed himself in the supposed action of the moment. After exposing the plate, I persuaded him to try it again, reciting the text and 'suit the action to the word.' The lines were addressed to a son by a parent, and were: 'I am no father to a thief!' He threw himself into the full spirit of the text and action, producing a result that excited the warm applause of the company and gave me a superb picture. Suppose I had attempted a head rest?"

The Leeds Convention and "the Iron Duke."—We had the pleasure of inspecting two photographs by Lawrence, of Dublin, at the Mayor's reception (City Art Gallery), and at the Exhibition Hall. The negatives were taken in the Library of Trinity College, Dublin, for presentation to Her Majesty the Queen. One was a photograph of a white marble bust, double life size, by the great sculptor, Sir Francis Chantrey, R.A., a very fine work by the famous artist, recalling the well-known features of "the Iron Duke," the enamelled inscription plate, shown in photograph, being affixed to the pedestal, one of a series in the celebrated College library. The other photograph depicts what may be termed an artistic record of Wellington's life and career. It is illuminated on parchment by Harry Foster Newey, one of the masters at the Birmingham Municipal School of Art. By this we learn that Wellington was born at Mornington House, Dublin, May 1, 1769, and died at Walmer Castle, Kent, September 14, 1852. There are some thirty-seven lines of Wellington's "titles and honours," bestowed by all the leading monarchs and governments of the world. At top, surrounded by a nimbus of rays, the word "duty" is displayed as being the guiding star or motive of the Duke's life and conduct. Beneath it a gracefully grouped trophy of arms and flags. Down each side runs a "riband," with the names of the leading events in Wellington's career from the time he joined the Thirty-third Regiment, down to the close, when he became "Queen Victoria's counsellor and friend." Four medallions at corners contain, respectively, portrait of Wellington, the Duke's set coat of arms, the Irish harp, and portrait of the donor of hust and record. Wreaths of shamrocks encircle the whole in honour of the great Irishman. A pretty group is made at foot of Irish emblems—the Round Tower, the Irish staghound, the Celtic cross, and the Dublin mountains for a background. Bust, plate, and record are the gift of Mr. D. J. O'Neill (himself a Dublin man), now a Birmingham resident, as the record states, with hearty good wishes for his native land. Mr. O'Neill is known to the photographic profession as the Secretary of the National Association of Professional Photographers. The gift is worthy of the great general, and is placed where it will be carefully preserved and shown to the visitors from all parts of the globe who yearly inspect the famous library of Trinity College, Dublin.

ABSORPTION PHOTOGRAPHY AND X RAYS.—The scientific interest connected with the Röntgen or X rays has brought out, through a large number of investigators, a great variety of phenomena bearing directly or remotely upon the original methods and results. While studying the work of others on the X rays proper, the recollection of an accident which the writer had in some photographic work led to a series of experiments along a line which may or may not be connected directly with the Röntgen rays. The experiments were begun about the middle of March, and are not yet finished. So far as the writer is aware, no work has been reported in just this line of investigation. The object of the experiments was to ascertain, if possible, if photographic negatives could be gotten similar to X ray negatives by the action of energy previously stored in certain bodies. The results of the experiments which are to be given seem to point very strongly to an affirmative answer. *Experiment No.* 1.—From a newspaper was taken a cut of a pair of eyeglasses, and from a glazed paper was taken another cut. These were exposed for about an hour to sunlight and were then removed to a dark room, and after cooling were placed over a common sensitive glass plate and very carefully and thoroughly wrapped in white cloth and paper, and then placed in a tight box and allowed to stand in a dark room for about one day. At the end of this time the plate was slowly developed and found to reveal the picture clearly, the one on the unglazed paper being slightly more distinct. A similar experiment was tried, using lamp instead of sunlight, and gave similar but not so strong results. *Experiment No.* 2.—At the same time that No. 1 was being carried on, a figure cut from the inside leaf of a book which had been in the dark for the most part for a year or more was, without exposure to light, placed over a sensitive plate. No results were secured in this case. *Experiment No.* 3.—Over a pine board was placed a black woollen cloth, and to this were fastened fragments of zinc, copper, graphite, silver, glass, rubber, and wood. This was exposed to sunlight for an hour, and after cooling was placed over the sensitive plate, carefully wrapped in cloth, and placed in a tight wooden box and kept in the dark room for about one day. Upon developing, only the wood and rubber showed much. *Experiment No.* 4.—On a small piece of pine board were fastened the following articles: muscovite, copper coin, mica, an iron key, and a piece of glass. The whole was then exposed to sunlight for an hour, taken to the dark room, and when cool all the articles were removed and the wood placed over a sensitive plate and thoroughly protected by wrapping in cloth and placing in a tight box in the dark room. After one day the plate was developed, and all the articles were revealed on the negative by light figures, but the iron key and the copper coin seemed best to shut out the light. Similar experiments were successfully performed by exposure to powerful incandescent gaslight and to incandescent electric light, though the results were not so intense as by sunlight. *Experiment No.* 5.—A key was placed over one side of a common Kodak roll film, and a piece of brass placed on the opposite side. These were placed in a dark box and connected with the two poles of a battery for several hours. When developed, a very faint shadow appeared. *Experiment No.* 6.—A piece of mica and an iron key were heated in an alcohol flame till the edges just began to be red-hot. They were then allowed to cool and were placed over a sensitive plate in a perfectly dark box in a dark room for twenty-four hours. When developed, there was revealed the shadow outline of each. *Experiment No.* 7.—A current of electricity from a dynamo, sufficient to produce a small spark, was passed through an iron key. The key was allowed to cool, and was then placed over a sensitive plate, in a tight box, for twenty-four hours or more. When developed, there was seen the shadow outline of the key. *Experiment No.* 8.—A fresh fern stem was placed over a sensitive plate, and, after being so kept for twenty-four hours, the plate was developed, and there was revealed the outline of the whole stem, with a much darker central portion corresponding to the circulatory system, all of which was very clearly brought out. In some of the experiments which have been mentioned there was contact with the plate, while in others equally good results were obtained without contact. Considerable skill and a rather long time were required in the developing process. The results described are but a few of those obtained along this general line of study. It will appear from these experiments that in no case did the light pass through the object to be photographed; and, further, that light is not necessary. All of these experiments, but especially those in which the objects were heated or exposed to an electric current, and subsequently cooled in the dark, indicate, first, that the photographic action is due simply to energy stored in the body to be photographed and afterward slowly given off, there being a great difference in the power of absorption and radiation in various substances; second, that this energy may be from other sources than luminous rays, if these only reach a maximum rapidity of vibration; and that, when this rate of vibration is reached, a molecular change in the silver salts of the photographic plate is started, with greater or less intensity, depending upon the character and source of the energy, and completed in the developing process. From certain researches now being made, the writer would venture the suggestion that possibly certion phenomena connected with the Röntgen photography proper may be in part explained by these general statements. He hopes to present, at some future time, a series of experiments of such a nature as to confirm this statement.—E. J. BADCOCK, in *The Scientific American*.

Patent News.

THE following applications for Patents were made between August 10 and August 15, 1896:—

CAMERA FRONT AND VIEW-FINDER.—No. 17,648. "A Combined Camera Front and View-finder." E. S. ULLMER.

FERROTYPE APPARATUS.—No. 17,772. "Improvements in Photographic Apparatus Specially Adapted for Ferrotype Dry Plates." G. H. THOMAS and B. WHITWORTH.

APPARATUS FOR DEVELOPMENT.—No. 17,819. "Improvements relating to Apparatus for Developing Photographic Plates." Communicated by W. Herrmann. Complete specification. F. W. GOLBY.

COPYING HOLDER.—No. 17,909. "The Unique Plate and Negative Printing-out Holder for Copying Photographic Negatives on Opals, Bromides, Transparencies, and Lantern Plates." I. RENSHAW.

FILMS.—No. 18,036. "Improvements in the Manufacture of Films for Photographic Purposes." B. ACRES.

KINETOSCOPIC APPARATUS.—No. 18,084. "An Improved Form of Camera and Lantern for Taking and Reproducing Photographs in Motion and Throwing same on a Screen." A. W. HARRISON.

COLOUR PHOTOGRAPHY.—No. 18,131. "Means for Reproducing the Colours in Photography, suitable also for Dyeing and Printing." Complete specification. J. A. MICHEL-DANSAC and LEO CHASSAGNE.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

August.	Name of Society.	Subject.
31	Birmingham Photo. Society	Last Day for sending in Competition Pictures for July Excursions. Harvington Hall, Dovedale, and Astley.
31	Bradford	*Trimming, Mounting, and Framing.* P. E. Newstead.
31	North Middlesex	Informal Meeting.
September.		
1	Brixton and Clapham	Ordinary Meeting.
1	Hackney	Paper by Mr. Child Bayley.
1	Gospel Oak	*Enlarging for Members.* Messrs. Gittens and Liscombe.
2	Borough Polytechnic	Open Evening.
2	Photographic Club	The Management of a Photographic Society.
5	Borough Polytechnic	Excursion: Wimbledon and Morden.
5	Bradford	Excursion: Selby.
5	Hackney	Excursion: Sewardstone. Leader, W. Selfe.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

AUGUST 20,—Mr. E. H. Bayston in the chair.

Mr. FRESHWATER referred to the recent death of Mr. William England, who, at one time, was a member of the Association, and to his work in photography from the early days of its discovery to the present time.

Owing to the near approach of the closure of the Traill Taylor Memorial Fund, and the expressed desire of getting in all remaining subscriptions at once, it was proposed by Mr. FRESHWATER, seconded by Mr. HENDERSON, and carried, that the amount of the independent subscriptions made by the members be made up from the funds of the Association to a sum of five guineas.

The HON. SECRETARY introduced the question of screens for process work, and referred to a paper by Professor Burton on the photo-mechanical processes in Japan. He had recently gone into the subject of cross-lined screens. The gradations are obtained by variations in the size of the dots which compose the picture, but which are all printed in the same density. The question that presented itself was, How were these dots made of different sizes in the negative? and the opinions were that it was due to diffraction. He would like to know what those present thought about the matter.

Mr. BECKETT thought that diffraction entered into the subject, and that the more intense the light the more likely it was to spread.

Mr. BANKS said the theory was that the screen acts in the same way as a pinhole.

Mr. BULLEN pointed out that it was the custom of process workers to change the form of the diaphragm during exposure to obtain certain effects.

Mr. HENDERSON could not understand why more use was not made of irregular-grained screens instead of the ruled screens. He thought a good screen could be made by coating ground glass with a black varnish, and then grinding down again, when the varnish on the raised portions would be removed, and a screen of irregular type would result.

The HON. SECRETARY said that the holes would vary in size in such a screen, and the half-tones would not be properly translated.

Mr. BECKETT thought the blocks were not so much to blame as the printing, the ink, and the paper used.

PHOTOGRAPHIC CLUB.

AUGUST 19,—Mr. W. D. Welford in the chair.

Mr. NESBITT showed a print of the "egg-eating snake" at the Zoo. The body of the snake was so similar to the groundwork of the cage or den in which it was contained, that it was not easy to distinguish the reptile. Mr. Nesbitt said his son had taken a series of negatives of the several actions of the snake in swallowing an egg. The photographs, however, would be improved if the body of the snake could be more easily distinguished from the floor of the den. He asked how this could be done.

Mr. BRIDGE and Mr. WELFORD suggested blocking out all except the snake.

Mr. TOTTEM suggested making an enlargement, which could then be altered or blocked out and a fresh negative made from it.

Mr. Drage showed prints from a negative of the moon, taken by Dr. A. H. Fison, who used a reflecting telescope with a mirror eight-and-a-half inches in

diameter, and a focal length of ninety inches. The size of the image was eight-tenths of an inch, the plates used were Wratten & Wainwright's ordinary plates, and the exposure was one-eighth of a second with a drop shutter. The photographs were taken at Hindhead, Haslemere.

Mr. Parfitt also showed photographs of the moon made with a telescope of thirty-six inches focal length, the mirror being four-and-a-half inches in diameter. He had enlarged the negatives to two-and-a-half inches diameter. This was the limit fixed by the granularity of the dry plate he had used.

Mr. Tottem proposed, and Mr. Nesbitt seconded, a resolution that the annual outing of the Club to Hampstead should be held as heretofore, and that the members of the London and Provincial Photographic Association should be invited to join in the function. This was carried unanimously.

North Middlesex Photographic Society.—August 17, Monthly Instruction Evening, Mr. J. MacIntosh in the chair.—Mr. F. L. Pither read a paper on

ELEMENTARY COMPOSITION,

in which he pointed out very clearly the errors many photographers fell into, and how a picture was composed. One point he insisted on was that you should not build on the centre line, whether in architecture or landscape. By means of crayon sketches on drawing paper pinned to the blackboard he showed different forms of composition, sketched from memory, of some well-known paintings. In the discussion that followed, Mr. Marchant said there could be no composition in a photograph, only selection. Mr. Mummery maintained that by introducing clouds and figures a certain amount of composing could be done. Several other members took part in the discussion. After a vote of thanks to the lecturer, voting on the results of the Burnham Beeches outing resulted in Mr. Marchant securing first and second places.

South London Photographic Society.—August 17, the President (Mr. F. W. Edwards) in the chair.—Mr. Roland C. Whiting (Ealing Photographic Society) gave a lecture on

RETOUCHING AND THE IMPROVEMENT OF NEGATIVES.

He said retouching was a wide subject, and he proposed to deal only with the subject of expression, which is the chief object of retouching. Photography fell very far short of what we should like it to perform. The dry plate did not render things as seen with the eye, owing to the fact that the plate was more sensitive to those rays which are invisible. The defect is not so noticeable in orthochromatic plates, but they do not render colour correctly in every case. Many people object to retouching, and that justly, because its power has been cruelly abused. People have taken up retouching without knowing the principles which underlie the whole practice of it. Legitimate retouching is confined to very small limits. It does no more than correct the colour values of a negative. Skill depends upon knowing what to do. In teaching retouching, I find that those pupils who are taught the whole principles before they go to work get on better than those who go step by step. They are like travellers who have studied the map and know something about it. Before dealing with the methods, we must be acquainted with our tools. The principal thing we employ is a desk. There is not a proper one in the market, for the reason they compel you to lie upon the top of your work. A desk may be made so that it takes negatives almost upright with a slight slope, and at the same time at a sufficient height. The upright position will be found in a long day's work to prevent a great deal of fatigue. This necessitates some means by which the hand should be supported. A table should form a support for the elbow. A T-square set on end forms a convenient rest for the hand. (These remarks were illustrated by diagrams.) Do not lay the hand on the negative—it is bad in principle—and do not hold the pencil close to the point. Too much light is bad, as it reveals many defects which do not print, thus rendering more work than is necessary. The light should be filtered. The ideal material for the purpose is "flashed" opal, which is now rather expensive. That which gives an idea of a flame fifteen inches away is the best density. It is desirable to have means of raising the negative diagonally when necessary. The usual materials for retouching are pencils, and sometimes brushes. In France a needle is used instead of a pencil. Needlework has gone out entirely in England. At present pencils of moderate hardness, B. S. Cohen's threepenny pencils, with round leads, are the best, HB and H. HH is useful when the others are too soft. Faber's are the next best. The lead should project about three-quarters of an inch. Glass paper glued to a piece of wood is the best for sharpening pencils. (The method of sharpening was demonstrated.) Payne's grey, tempered with Indian ink, is the best material for spotting out. It gives a similar colour to that contained in the negative. Do not use too much Indian ink. This colour can be used as a wash or a stipple. The use of the knife was explained. The principles which should guide a retoucher were then explained by means of diagrams on the blackboard. In conclusion, he said, Never do too much; rather do too little. Above all, remember that the negative is nothing more than the means to the end, the result of which is a picture.

FORTHCOMING EXHIBITIONS.

1896.

August 25–29 ..... Royal Cornwall Polytechnic, Falmouth. Secretary, E. F. Kitto, Falmouth.

Sept. 24–Nov. 7 ..... Photographic Salon, Dudley Gallery, Piccadilly. Alfred Maskell, Dudley Gallery, Piccadilly.

,, 28–Nov. 12 ... Royal Photographic Society. R. Child Bayley, 12, Hanover-square.

Dec. 1896–Jan. 1897 Bristol International.

Correspondence.

THE EXPANSION OF PAPER.

To the Editors.

Gentlemen,—I have read with surprise your extract from *Autotype Notes* upon the above subject, signed by E. W. Foxlee.

Paper, like other fabrications, has its vagaries, and is very much tampered with by its manufacturer.

In conformity with the above title, I should have expected something more exhaustive and scientific from the pen of such an authority as Mr. Foxlee; instead, we are treated to a series of dodges and shifts by which mistakes in negatives can be cobbled up or compromised in mounting! Why rush into print at all if we cannot impart even a moiety of useful instruction? The bare idea of pulling a man's broad face to make it look longer is absurd, and should not be advised under any circumstances.

I think many readers would have been glad had Mr. Foxlee given us an insight into the tricks of paper-makers and the constituents of paper itself, beginning with the fibre of the pulp in the vat, describing its nature and source, and its passage from the vat to the receiving apron, and on through the various operations until the web becomes cut into sheets, and, having done so, instruct us how to produce our work on the material without the inconvenience of encountering stretching, distortion, or contraction.

With man very few things are impossible; for instance, if I take two sheets of paper, cut from the web transversely, and paste one sheet upon the other, so that one shall be lengthways and then broadways of the web, any work produced, photograph or drawing, upon such a combined sheet, however treated, will preserve its original proportions.

Paper will only stretch to a fixed extent, no matter how long the wetting is continued; therefore, if I coat a sheet of paper with gelatine, and while it is thoroughly wet squeegee it on to a greased or chalked plate, stripped when thoroughly dry, such a sheet will not further expand in either direction, however long the contact with water continues. By this means, during the last thirty years, I have executed, reduced, and enlarged photo-litho transfers from chromo lithographic copies, extending to eighteen colours, and these, when transferred to stone, are found to register together as accurately as if drawn on stone direct. A former method of mine was to soak the sheets in water, and then glue them by the outer edges into a rectangular frame, and, when dry and cut out of the frame, it was fit for use. There is a wrinkle for P.O.P. and other sensitive-paper manufacturers by which they can supply their customers with a paper suitable for engineering and other purposes.

Photographic Works, 119, *Clonliffe-road, Dublin,* *August* 19, 1896. Joseph Lewis.

THE BRUSSELS INTERNATIONAL EXHIBITION OF 1897.

To the Editors.

Gentlemen,—But little attention has been given in this country to the International Exhibition that is to be held in Brussels next year, probably for the reason that, until lately, it was wholly a private enterprise. The recent interest taken in the project by the Belgian Government has, however, invested it with considerable importance, and has converted it into an Exhibition well worthy of the serious attention of manufacturers and industrials generally. The more important of our foreign competitors have signified their intention of participating in the Exhibition. France has already made a grant of 35,000*l.*; Germany has appointed a powerful Government Commission; in the United States a grant has been made by Congress; and a large number of other countries have accepted the invitation to be present sent them by the Belgian Government. Our own Government has recently intrusted to an influential British Commission, under the Presidency of Sir Albert Kaye Rollit, the interests of this country at Brussels; and it now remains for our manufacturers to decide whether they will best consult their own interests by combining to form a representative British Court, or whether they can afford to leave the opportunity for extension of business in the hands of our chief rivals, Belgium, Germany, the United States, and France. In urging them most seriously to consider, if not the direct advantages of participation, at least the great danger of abstention, I appreciate fully the cost and inconvenience inseparable from taking part in an Exhibition; and, if the one to be opened in Brussels next April had remained the offspring of a private company, I do not think it would have been worth the attention of manufacturers. But, having been adopted by the State, the International Brussels Exhibition of 1897 takes rank among the more important of its kind; and I do not think that this country can afford to be absent, or not to be worthily represented there. This is a question for exhibitors to determine, and to determine soon, as the time at their disposal is even now restricted. I shall be obliged to intending exhibitors if they will, at their earliest convenience, place themselves in communication with me, in order that I may furnish them with detailed information. I may add that the Brussels Exhibition is universal in its classification, embracing all branches of art, industry, and science.—I am, yours, &c., James Dredge, *Executive Commissioner, British Section.*

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:—

P. D. Roberts, 2, High-street, Shaftesbury.—*Photograph of half-plate group.*

Frederick Holmes, 92, Horningsham, Warminster, Wilts.—*Two photographs of the Rev. Canon Jacob and family of Horningsham, Warminster, Wilts.*

RECEIVED.—GEM DRY PLATE COMPANY; T. G. SNOWDEN.

W. E. A. DRINKWATER.—It is not supplied commercially.

RADIOGRAPHY, &C.—ELECTRIC. 1 and 2. Yes, to both questions. 3. A thin coating of glue or indiarubber solution would probably answer.

DEVELOPER.—R. GRIFFITH (Newquay). The solutions appear to us to be too highly concentrated, hence, probably, the fog, Were we using that particular formula, we should at least double the quantity of water in each case. Try this, and let us know the result.

ORIGIN OF LENS.—S. A. E. The firm named on the lens ceased to exist some years ago. It was not the actual maker of the lenses it sold. They were made in Paris, probably by one or other of such houses as Jamiu, Hermagis, or others. The lenses were, however, or such as we have seen, very good for that period.

INJURED LENS.—T. BRUNTON. As one of the glasses is "cracked right across," there is nothing to be done but get it replaced. That had best be done by the original maker. We do not know any one who would do the work cheaper than him—that is, if the original excellence of the instrument is the principal consideration.

ASPECT FOR STUDIO.—AMATEUR (Wilts). If you have a choice of aspect for your studio, you cannot do better than select north. The proportions named will do very well for amateur purposes, but for professional work, as your letter implies the studio may eventually be used for, three feet longer and two feet wider would be better.

WORKING HOURS.—SWEATED. There are no recognised hours of labour in the trade. Of course, in the case of females and young persons, where several are employed, the Factory Act applies. This is not so in your case. You should have arranged the business hours at the time you took the appointment. The law will not aid you in any way.

PHOTOGRAPHIC PAPERS.—J. HARRISON says: "There are other papers besides Saxe & Rives's in the market for chloride paper, and larger; will you kindly give me the address of the firm, as I shall require it by the ream?"—In reply: Write Messrs. Otto König & Co., 27, Cross-street, Finsbury-pavement, E.C., who are agents for the papers you want.

GREEN FOG.—GREEN FOG. Possibly the simplest plan would be to change your plates and developer. It is caused by under-exposure and forced development. To remove it, convert the deposit into silver chloride and apply a ferrous-oxalate developing solution. This is the only remedy we can suggest; but we have not much confidence in it.

BOOK ON STUDIO CONSTRUCTION.—J. M. J. NOCK says: "I am about to build a photographic studio, and would like to consult some good work, or article, upon the question." Could you recommend me to same?—In reply: Messrs. Marion, Soho-square, publish such a work, by Mr. Bolas, which will probably give you all the information you require.

CARBON WORK.—T. MACKEY says: "I have some very thin negatives which I wish to print in carbon. Could I get extra vigour in the prints by sensitising the tissue in a much stronger solution of bichromate of potash than that usually recommended?"—No, just the reverse. Use a weak bath, give a short immersion, and print in a feeble light, if you wish increased vigour.

FIXING POWER OF HYPO.—W. L. NASH says: "The article in your latest number, on the fixing power of hypo, is of great interest. I do not at all care to save expense by using the minimum quantity of hypo, but it would be of real use to me to know whether or not four ounces of commercial hypo, dissolved in a pint of water, is sufficient to fix one 10×8 bromide print."—In reply: Yes.

BACKGROUNDS.—BACKGROUND writes: "Will you kindly inform me what would be the best material for painting backgrounds upon, and also the sort of oils, as I have tried ordinary oil colours and have not succeeded very well?"—In reply: Unbleached calico or sheeting. Ordinary flatting colour, that is paint made with a large proportion of turpentine and very little oil, so that it dries dead instead of glossy. It may have an addition of japanners' gold size, which will give it body and facilitate its working.

SPOTS ON NEGATIVES.—MERCURY says: "I am greatly troubled with metallic spots in my negatives, sometimes taking the form of comets, splashes, and at others so small that they are scarcely seen with the naked eye, but are quite opaque in printing, causing considerable annoyance in spotting prints. I am using pyro and ammonia development, and am practically careful in every respect."—In reply: Send us a negative with the markings complained of. We shall then be in a better position to suggest a cause for the defect.

VALUE OF INVENTION.—INVENTOR. We can give you no idea whatever as to the commercial value of the invention, nor could we do so even if we had seen it or knew its points. The best thing to do is to search out what has been done before in the matter of instantaneous shutters—no easy task, and, if the thing is really original, obtain provisional protection for it, and then submit it to a manufacturer who would be likely to take it up. You seem *very* sanguine about your invention. May we remind you that this is the case with the majority of those who invent anything, and that they, for this reason, quite ignore what has been done before?

STAINED MARGINS OF NEGATIVES.—T. BARNES. The stains on the edges of the negatives are due to the use of stale plates, notwithstanding what the local chemist may say to the contrary. Chemists and druggists who deal in photographic goods as a rule have very little sale for them, as the majority of workers prefer to purchase from regular photographic dealers. They then ensure a greater certainty of obtaining what they require in the best condition. It is no good complaining to the makers of the plates, as it may be relied upon they were in good condition when they left their hands, and we fear you will get no more redress from the druggist. Probably he does not know that plates, and some other photographic materials, deteriorate by keeping.

FALLACIOUS PAPERS AT PHOTOGRAPHIC MEETINGS.—SCRUTATOR writes: "Is any one supposed to be in any way responsible for the papers read before recognised photographic societies? I mean, can any one read a paper, which may be the most misleading nonsense imaginable without that paper being somewhat judged of beforehand by the Committee or Secretaries? I ask the question because I sometimes see reports in the JOURNALS of papers that are erroneous to a degree."—The papers read at the meetings of the different societies are solely on the authors' responsibility, and the societies take none for them. There is a rule, we believe, of the Royal Photographic Society that all papers are to be submitted to the Council before they are read, but it is doubtful if it is acted upon.

RESITTING.—YOUNG PROF. writes thus: "Will you please tell me what is the rule with regard to the giving of resittings in London studios? I started business here in the spring, and I find that all the sitters want resittings—two, three, and four times—before they are satisfied, and they will not pay anything for them. All promise good orders if I get portraits to please them, but when I do the orders do not come off. This, of course, reduces the profits to next to nothing."—There is no set rule as to resitting in London any more than there is elsewhere. Every artist tries to please his sitters. As our correspondent says *all* his sitters require several resittings, may we mildly suggest, as he is a young beginner, there may be a good reason, on his part, for it? Be that as it may, as we have just said, there is no set rule in the matter.

CLOUDS IN CARBON PICTURES: TONING PLATINOTYPES.—J. PORRITT writes: 1. "I shall be glad if you can suggest an easy and effective way of adding clouds to carbon prints. So far my success has depended upon making a positive with clouds, and then a second negative to print from. Working up clouds on the original negative is not always a success with me. 2. Can you inform me who is the agent for the sale of Mr. James Packham's catechu powder for toning platinotypes?"—In reply: 1. The plan you have been following is the best if the cloud negatives are not the same size as the landscape negative. The working in of clouds on the original is the one most generally followed with large sizes, but it requires skill, and that is only acquired by practice. 2. We do not think there is any special agent. Better address Mr. Packham, Katherine-street, Croydon. He will, doubtless, supply you.

PLATES BROKEN IN TRANSIT.—PLATES says: "I shall be much obliged if you will give me your opinion on the following:—In January last I ordered one dozen 12×10 plates to be sent by passenger train, and they arrived carefully packed but all broken. I advised the dealer of such two or three days later, and also sent in claim to the railway company, and later they refuse to pay damages, as the goods were not marked glass, and I refuse to pay also as they are useless, but have told the dealers I will pay for a perfect dozen if they will send them, and they refuse, and have returned them, and they will not take them in. They are now in the hands of the railway company. Have since received a County Court summons, and shall fight it out."—In reply: We are under the impression that the company are liable; but, of course, railway-company like, they will wriggle out of their liability if they can. But possibly some of our commercial readers learned in such matters will let our correspondent have the benefit of their ideas on the point.

COPYRIGHT.—COPYRIGHT says: "Enclosed print has been sent to me this morning. A number is wanted, not for sale, but to advertise an embrocation by a local chemist. This print is evidently a copy, to all appearance. Could you kindly ascertain if this is a copyright subject, as I make it a rule never in any way to cause annoyance to my fellow-tradesman. The particulars on back of print, as I received it, answer for itself. I do not know whether it is customary for you to ascertain whether prints are copyright or not."—In reply: The print has been returned. We may say that we have already seen a reproduction of this identical photograph in a popular magazine, and, if you copied it, you would in all probability not only "annoy" a fellow-tradesman, but you would run the risk of an action for infringement of copyright. We do not undertake to ascertain if a photograph has been registered. It should be worth your while to write to the Secretary of the Photographic Copyright Union, Mr. H. Gower, Photographic Section, London Chamber of Commerce, Botolph House, Eastcheap, for literature bearing on the subject of copyright—a subject in which, notwithstanding all that has appeared on it recently in this journal, you must pardon us for saying you do not appear to be well up in.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1896. Vol. XLIII.—SEPTEMBER 4, 1896.

Contents.

OUR FORTHCOMING ALMANAC.

The time of year has arrived when it is necessary for us to take in hand the preparation of The British Journal Photographic Almanac for 1897. A feature of the volume for the past thirty years has been the co-operation of numerous friends and readers of the Journal, and the Editor takes the opportunity to express the hope that the support so kindly placed at the disposal of his predecessors may be continued to him.

We especially invite contributions on topics of practical interest, and should feel obliged if the articles and any accompanying sketches are sent to us at the earliest possible date.

Secretaries of Societies, and especially of those established since the appearance of the last Almanac, will oblige us by forwarding lists of officers and other details for inclusion in the Directory of Photographic Societies, in order that the list may be made as complete as possible.

The Publishers wish us to remind intending advertisers that the announcement pages of the Almanac are already filling rapidly, and that, to ensure insertion and good positions, orders and copy should reach them without delay.

EX CATHEDRÂ.

We are asked to state that Thursday, September 10, between the hours of 9 a.m. and 9 p.m., is the only day for receiving unpacked exhibits for the Annual Exhibition of the Royal Photographic Society. If packed, they may be sent at any time up to Wednesday, September 9. In both cases they must be delivered at 12, Hanover-square, W., and not at the Gallery, 5A, Pall Mall East, S.W. Full particulars relating to the Exhibition can be obtained on application to the Assistant Secretary, at the Society's rooms, 12, Hanover-square, W.

* * *

Adverting to our remarks of last week on the issue of a circular by a firm of diarists relating to the coupon system of photography, we have received a letter on the subject from Mr. Drinkwater Butt, of Carlisle. Mr. Butt, like Mr. Byrne, had also had the circular from which we quoted, and he forwards us a copy of his reply thereto. It runs: "Your circular to hand. I shall have much pleasure in agreeing to the arrangement therein proposed if, on your part, you will agree to present to each of my customers who pays 1*s.* (the price of [your] almanac) for one midget photograph before the end of 1897 one of your diaries, value 4*s.* (the price I get for a cabinet photograph), and I feel sure that 'in every instance other copies (of your diaries) will be undoubtedly ordered, and further business result, and it prove a *splendid advertisement* for *you*.' I shall, of course, 'only appoint one *diarist*,' so shall be glad to hear from you per return." Mr. Butt's rejoinder is certainly neat, apposite, and reasonable.

* * *

Mr. J. A. Kay, of Burlington Studio, 211, Lord-street, Southport, writes that he also received the circular. Mr. Kay says: "I wrote, saying I failed to see what advantage I should gain; and to-day I received the enclosed letter from them. I have, however, written to say that they had better make arrangements with some other photographer who would do something for nothing." The reply referred to by Mr. Kay is as follows: "Your opinion of our scheme is not that generally held by the leading photographers in the United Kingdom—we presume that scarcely one person in a dozen who presented a coupon to you would be satisfied with one proof. Further copies are sure to be ordered in almost every case, for which you would obtain your full fees. However, if you do not look at in this light, we will make other arrangements for your town."

The copy of yet another circular has been sent us by Mr. Alfred Freke, of Cardiff, who asks if we know anything of the mysterious process to which it refers. We do not. It will be observed that the circular refers to a secret method for preventing halation, and a charge of five shillings is asked for the information. We quote the circular: "Every photographer should be possessed of the knowledge whereby interiors of every description can be photographed without the use of any special plate or backing. All fog or halation entirely done away with—by a very simple means, and without cost—thus enabling the photographer to expose the very deepest shadow. The undersigned will forward the information (which is private) on receipt of five shillings; but so that no unfair advantage might be taken of the discovery and to enable every photographer to gain the information at the same time, I beg to intimate that the necessary particulars will be forwarded on September 10, 1896."

* * *

The backing of plates in order to obviate or minimise halation is such a simple matter, that we should be surprised to hear that any photographer had paid five shillings for information on the subject other than that which has times out of number been given in these pages. We also feel bound to add that the practice of vending and purchasing secret processes is one which experience has before now shown to have nothing in its favour.

* * *

In the early part of the year, the London process-block makers held meetings with the object of coming to an agreement in regard to the minimum prices to be charged for half-tone and line work. We believe that the prices agreed on, almost unanimously, by the trade, were 3½*d.* per inch for line work and 8*d.* per inch for half-tone. The strength of the position taken up by the process workers lies in the strict observance of the prices agreed upon and unanimity of action. We presume that the latter does not exist, as there lies before us, as we write, a quotation of 2½*d.* per inch for line work and 7*d.* for half-tone. Possibly, however, since the date of the meeting the minimum prices have been reduced by agreement

CERAMIC PHOTOGRAPHY WITH GELATINE.

Ceramic photography, as generally practised in this country, is based either upon the dusting-on or powder process, or upon the substitution process, in which a silver image is converted, by "toning," into one or other of the metals, which will yield a suitable colour when fired in the muffle furnace. There is, however, another method by which ceramic photographs can be produced, namely, by printing the image in "carbon" tissue containing a vitrifiable colour, instead of the ordinary pigments, and then developing it on, or transferring it to, the plaque, and afterwards firing it into the ware. This, at first sight, appears a very simple way of producing ceramic photographs; but it is not quite so easy as it seems in practice, as we shall presently explain.

In our last issue we gave an extract, from Eder's *Jahrbuch*, of a process based upon the latter method, as worked out by Herr Haberditzl, of Vienna. Briefly, the process is this. An oxide of a metal—the black oxide of iridium is the one recommended by the author—is ground up with water, and then added to a solution of gelatine, sugar, and water. This mixture is then poured on to levelled glass plates, and, after the gelatine has set, the plates are reared up to dry. The plates are then sensitised in a solution of bichromate of potash, and, when dry, printed in the usual manner. When printed, the film is coated with plain collodion, and then washed in cold water to remove the unaltered bichromate. Next, a sheet of white paper is laid upon the film and warm water added; then, when the film begins to leave the plate, it is stripped off and developed, with warm water, in the same way as a carbon print. After aluming and treating with alcohol, the image is transferred to the ware, and when dry the collodion is removed by a solvent. The picture is then burnt in. So far as the manipulations are concerned, they are precisely the same as those of Fargier for working the carbon process, which he patented in 1861—three years before Swan patented his method.

There is no difficulty whatever in producing the photographic image in vitrifiable pigments by the usual method of carbon printing, if those pigments be used in the tissue in place of the ones usually employed. The difficulty is to fire them into the ware, whether that be enamel or porcelain. The chief trouble is, that, as the heat is applied, the gelatine cracks, fizzles up, and leaves the plaque, bringing the image away with it in parts or entirely. Different methods have been tried for getting over the difficulty, and with more or less success. The Autotype Company did, some years ago, produce very good burnt-in photographs by the carbon process, and they showed some large sizes on porcelain plaques and tiles at one or two of the photographic exhibitions. They also, for a time, worked the method commercially, but eventually gave it up, because, we are told, there was no demand by the public for the pictures. The method by which they overcame the fizzling trouble has, so far as we are aware, not been published.

About a dozen years ago, Mr. Thomas Bolas patented a method of producing ceramic pictures by the carbon method. The way he got over the fizzling difficulty—and that formed a part of the patent—was by placing a lump of cyanide of potassium in the muffle or oven, the vapour of which tends to moderate the spitting-off tendency of the gelatine film. That was one way, but the one he gave preference to was to inject a fine spray of a solution of an alkaline salt, such as borax, cyanide of potassium, silicate of potash, &c., into the muffle.

In Herr Haberditzl's article no mention is made of the way the fizzling is prevented. It is, however, stated that a suitable gelatine is important, and that the author had made some four hundred experiments before he hit upon the right kind and the correct proportions. These are given as follows: Hard gelatine in the proportion of 7 grammes to 100 grammes of water with 6 grammes of sugar added. The colouring matter is 8 grammes of black oxide of iridium ground in 50 grammes of water until the latter has almost all evaporated. A hard gelatine, one would imagine, is not the most suitable for the work, but it is noteworthy that the sugar is in much larger proportion than is generally employed in the manufacture of ordinary carbon tissue; also that the film, when dry on the glass, must be very thin, as the quantity given, when filtered and finished, will not much exceed 4 ounces; and this, it is said, is sufficient for thirty plates 9 × 12 cm., nearly 5 inches by 4.

In case any of our readers are inclined to try Herr Haberditzl's method, it may be well to mention that the oxide of iridium is rather an expensive substance. In a wholesale price-list now before us it is quoted at eighteen shillings a drachm, and the quantity given in the above formula is some-

thing over 2 drachms; experimenting with the formula, as given, will therefore be somewhat costly. However, cheaper oxides may be employed in the preliminary experiments, the oxide of manganese, for example, the price of which is quite nominal. The oxide of manganese, if used, will give a pleasing brown colour when burnt into the ware.

A New Test for Wood Pulp in Paper.—The well-known defect to which paper from wood fibre is liable renders acceptable any test for ascertaining its presence. According to Herr F. Wolesky, diphenylamine is very useful for this end. One gramme of the latter is taken and dissolved in fifty c. c. of alcohol and five or six c. c. of strong sulphuric acid, and the sample is immersed in this solution. According to the quantity of wood pulp present in the sophisticated paper so will a more or less deep orange colour develop and increase on drying.

A New Developer.—According to M. Edwin Ackermann, in the *Bulletin* of the French Chemical Society, quinine is capable of filling a new *rôle* in photography. It is an old story how a photographer was almost driven insane by the repeated production, upon development of plate after plate, of a death's head upon the forehead of one of his sitters, and how the ghastly joke was explained by the sitter having made a preliminary sketch on that part of his face, using a solution of quinine for the purpose. It is, as we say, an old story that once used to pass current, though as to its truthfulness we will not vouch; but, according to the above-named writer, if two grammes of sulphate of quinine, eight grammes of zinc dust, and forty cubic centimetres of water are heated at 100° C. in a closed tube for ten hours, a liquid with strong reducing properties is obtained. It is stated to act as an excellent developer, producing a clear and sharp image.

Photo-chemistry and Thermo-photo-chemistry.—Under this heading is an interesting abstract in the *Journal of the Chemical Society* from a paper by Rodolfo N. Amici. The author discusses at length the various chemical changes accompanying photographic action. Although light can cause both endothermic and exothermic reactions to occur, the former only proceed, as a rule, to a very slight extent, owing to the reverse exothermic reaction setting in between the decomposition products. The usefulness of chemical sensitisers is due to their being able to act exothermically with certain of the decomposition products, and so facilitate the photographic action. In exothermic reactions the light acts merely as an exciting agent, but in endothermic reactions it plays the part of a source of energy. All endothermic photographic reactions cease when the light ceases to act, and those reactions which continue in the dark after cessation of the light action must be exothermic.

New Application of Röntgen Rays.—At the last meeting of the Paris Academy of Sciences, M. Chas. Henry described a new application that he had devised which permitted the obtaining of luminous shadows instead of the ordinary photographic results. He coats a screen with phosphorescent sulphide of zinc, and, covering this with a sheet of needle paper, places upon it the object to be radiographed. Then placing the Crookes' tube in action for about five minutes, he withdraws the screen, the zinc-covered surface of which has acquired a phosphorescence which will last for some time. The image so produced can be increased in brilliancy and prolonged for about a quarter of an hour by exposing it to dark heat radiations. Upon bringing the plate into a dark room, one can apparently see the luminous outline of the object traversed by the Röntgen rays, with all its variations of permeability represented by differing degrees of luminosity. This process is useful in those cases where it is not needful to preserve a permanent record, and lends itself readily to lecture purposes without having to wait for the development of a plate, as would be necessary if a plate had been used.

Such a process, however, would not be available for many of the practical purposes for which the Röntgen rays have already proved so very useful. For example, Mr. Watmough Webster has shown us a very interesting sciograph he recently took of an infirmary patient. The poor fellow had been working with his hands in some sand, into which some broken glass had fallen, and a number of small spicules of which had lodged in the flesh of the back of the hand. Several pieces had been removed, but he still had great pain, which he was sure was caused by one remaining piece. The surgeon was unable to find it, and, as a last resource, sent him to Mr. Watmough Webster. "I could bear the cutting," he pathetically said, "but could not stand any more probing." A negative was taken, and the patient walked off with it to the infirmary, returning in about an hour quite gleeful, with the spicule of glass removed and carefully brought in a pill-box.

The Phosphorescent Tablet.—There is no doubt that for a tablet to be used as suggested by Mr. Henry, the easiest mode of working would be to purchase some Balmain's paint, which can be obtained commercially with little trouble. The tungstate of lime recommended by Herr Arnold, as recently described by us, is best obtained in the form of the mineral tungsten. A solution of tungstate of copper in tungstate of calcium also glows with equal brilliancy as natural tungsten. A further note on the tungstate is found in Dr. Fernando Giazzi's paper. By a certain process of heating in a coke furnace in the presence of oxygen, the tungstate is reduced to a white saccharoid mass, which gives a much more brilliant glow than ordinary tungsten; but the effect can be further intensified by pulverising the mass and repeating the process, the final product, which Dr. Giazzi terms the bisaccharoid form, being, in his opinion, the best substance for shortening the exposure and intensifying the brilliancy of photographs taken with the Röntgen rays.

DIGRESSIONS.

IX.—Give the Man a Chance.

One of the most trying operations in photography is that of "taking a group." I, of course, mean the group of commerce, the wedding group, the football and cricket groups, the beanfeast group, to which I must add the Convention group. All art abandon ye who venture here; there is no use for it. All the skill of the operator must be used to keep "the heterogeneous conglomerations of human atoms" quiet. How often in his despair is the much-enduring operator inclined to shout, "Give a man a chance!" This he did at the taking of the Leeds Convention group, or somebody did for him, with remarkable effect. It is a large order to pose, even if you omit all posing, one hundred and thirty people out for a holiday, all with the fatal birthright, or acquired right, if not the gift, of photography in them; all, according to the usual teaching, the best of sitters, but all really the worst, for, the more a man knows of photography, the worst sitter is he, the worst in the world except the actor, who, by the nature of his particular branch of art—for *he* claims to be an artist, although he is only an interpreter of other men's words—always overdoes it; and the photographer, when he sits, usually tries to be quite natural, so effectively that we immediately see it is a sham.

It is in the Convention group that photographers show they are as awkward a lot of people as any they have had to complain of in their professional experience, and should lead them to have a fellow feeling for ordinary humanity when it gets paralysed by the lens and camera-shy. It will be noticed also that they are as learned in, and as fond of giving off, the usual inanities as the familiar funny man we meet with in every group. I noticed the President couldn't help it himself. And who shall blame them? They are built as other people, "warmed and cooled by the same summer and winter; if you tickle them, do they not laugh," and have the same yearning for a joke? Many of them have had what may be called the "group jokes" played off on themselves all the year; shall they not retail them at their one opportunity in the year, when they have a victim all to themselves? Shall they not find it delightful to escape from

the storm and stress of portraiture, and; instead of always striving to please their sitters, become the sitters themselves, with all their little humorous ways?

By the way, did not a dozen or so of the Conventioners at one of the excursions—York, to wit, in the ruins of St. Mary's Abbey, which ought to have compelled more seriousness—form a solemn league and covenant to reverse the usual procedure, and, instead of touting for sitters, be the sitters themselves, and send out a tout to find photographers to come and photograph them? The tout (who must have spent much of his life as a doorsman) was so efficient as to beguile most of the photographers who had any plates left. It was noticed, however, after a while, that the grounds in which the little episode took place were gradually cleared of photographers, and the news of brigands, who "compelled all creatures to their will," must have spread, for no more, I hear, came near upon whom the wily tout could exercise his blandishments.

But to return to our chances. That simple exclamation, "Give a man a chance," was perhaps more effective than any other words could be. It appealed to the tender feelings of most of those present, it was a personal appeal to those who must have been through the mill many times. The "funny man" seldom realises the mischief he does, and the possible strain the photographer puts on himself to neutralise him without offence. To do this, he has to "forsake all others," as the bridegroom is enjoined to do in the marriage service, and devote himself to the idiot. Certainly the zany may be good-tempered and only thoughtless, in which case he is easily suppressed by a few judicious words; but there are others who think their stupid jokes invaluable, and insist on letting them off whatever happens. The photographer's smiles usually hide the vexation; but under such circumstances I once picked up my camera, and said that, if they wanted me, I would return when that man had got rid of his witticisms and realised his rudeness. It was quite effective, and, curiously enough, that man was my friend for ever afterwards.

There are many certainties that are miscalled chances. One of the most annoying criticisms on his work a true artist can hear is, "How lucky you were to get that beautiful effect on your subject," particularly when he knows that the subject has been passed by many photographers, camera in hand, and not recognised as a subject at all. There are some subjects that are beautiful for a few minutes only in the day; these are not seen, or not recognised if seen, by the wandering thousands, but the artist should have the requisite perception to see the possibilities under any of its aspects, and the patience to wait; or the subject may have pictorial capacities at any time of day, given a few additions or alterations which the artist should know how to make—some figures, perhaps, or cattle, or even an added stick or stone. The usual photographer may take it as he finds it, and produce "the usual thing," the artist may make the necessary addition and produce a picture, but he ought not to be accused of "chance." This ought not to be chance at all, for chance is an event that happens, falls out, or takes place, without being contrived, intended, expected, or foreseen—a fortuitous event. Here, perhaps, we discover one of the differences between the photographer who has made a long study of his art and the one who makes merely a business of it, or who has not gone further than the usual manipulation, and could make his own emulsion while knowing nothing of the causes of pictorial effect. Neither is it the chance of the photographer who would rely on the study of other photographs only, as Mr. Child Bayley suggested in the paper he wrote (not officially) without sufficient study. The skill to drop a pebble pictorially in the right place is the result of years of study of more than unexplained photographs.

There are some chances that every photographer has a full right to expect and depend upon as certainties. These are apart from his subjects. I allude to the matter because I have five or six instances brought to my attention this year, but I will refer to one only as a sample.

When we go to a great establishment and pay a great price for our apparatus, we ought to be able to place the greatest confidence in that apparatus. This is what one of my friends unfortunately did, and what I should have done myself without hesitation. My friend, a very skilful amateur, had such faith in a hand camera by a maker who claims to be at the top that, without testing it, he took it to Northern Italy and exposed the usual grosses of films. His part of the harvest of the year consisted of these films, and a very valuable contribution they ought to have been; but, when he came to develop them at home, he found that each one was blackened over by the action of light, which entered in some mysterious manner. Now, this photographer returned from abroad on purpose to join some friends in a week's excursion to a Midland county. The defective camera was sent to the maker, who put it right, and, with profuse apologies, assured the miserable owner that there would be nothing to fear for the future. Confidence returned. He had no opportunity of developing a plate—and why *should* anybody be bothered with experiments—and exposed many dozens on splendid subjects, in most perfect weather, in the most delightful time of year. It must be remembered this was one of our most skilful picture-makers; his pictures were badly wanted; they were invaluable; the coming exhibitions will be desolate without them. These films were also found to be blackened by light, which found its way into the amended camera. Many a man has eased himself of the burdens of this wicked world for smaller misfortunes. Now, where does compensation come in? Money could not satisfy the claim. I don't mean for the wasted films, or even travelling expenses, but for practically the year's work and the disappointment of the world. This is a matter which wants settling, but the making of precedents is costly. There ought to have been no possibility of chance here. You ought not to merely "happen" to get a light-tight camera, or a good lens, you ought not to have to try whether a first-rate instrument is good before you use it. It would be no great trouble for a maker to *try* a camera before sending it out, and I give this manufacturer credit for being as vexed over the matter as his unintended victim.

Now we are talking of hand cameras, I may just whisper that another friend of mine is having one made that is expected to do everything but speak. I listen to the frequent descriptions of it with awe, and my own special, but faint, hope is that it will take a photograph. My friend is doing all he can to make it a success. He will not want it until the early summer of next year, and is already beginning to learn its mechanism from the elevations, plans, and specification. He thinks he may know something useful about it by Christmas, but I doubt it. Good intentions don't turn dynamos. I also know of other hand cameras on the stocks to be launched as the amateur fashions for 1897.

The conclusion we may come to is, shortly, this: As a rule, the best chances a man has are those he makes for himself. It is not true that the best pictures are the result of happy accidents. If it were, then that miracle would come about of the best luck happening to the same individuals for a series of years. The customary visitors to exhibitions always know from whom to expect something good, eccentric, or original. A skilful and resourceful photographer may be deprived of his usual chances, the landscape man may not be able to take his annual excursion in search of the picturesque, the portrait or figure photographer may not be able to meet with a good model, but they are not lost. Some of their material expedients may come from without; their chief dependence is within. By virtue of their skill and resourcefulness these defaults should be help to them rather than the reverse. It brings out their reserve powers, induces them to break out in a fresh place, be more original, and not only to please themselves in a new way, but startle their usual admirers by their command over difficulties. These men make their own chances, and what is called their "luck," at any rate in pictorial photography, is the result of a profound study of art, not only as circumstances permit, but as their love of it compels.

H. P. Robinson.

NOTES ON ORTHOCHROMATICS.

It is astonishing to find that thirteen years after the discovery of the principle of colour-sensitising plates by H. W. Vogel, and at least ten years after this principle was successfully applied to English made plates, anyone should be found who is sufficiently ignorant of facts or sufficiently confident of his own powers of experiment to

stand up as the champion of ordinary *versus* colour-sensitive plates, particularly for the reproduction of pigmentary colours.

I purposely state "pigmentary colours," for many of the strongest supporters and most constant users of colour-sensitive plates admit that in the summer, when natural objects are illuminated by very powerful white light, the local colour is to some extent masked, and therefore the advantage of orthochromatic plates is, to some extent, minimised.

Before it is possible to accept any tests as conclusive, it is essential that some common ground should be chosen from which to start, and, if a really valuable test is to be made, it must be not only upon pigmentary, but also on spectrum, colours.

To test the luminosity of pigmentary colours, whether in the form of coloured papers or as actual patches of artists' pigments, it is necessary that some method should be adopted by means of which, once for all, their relative luminosities should be measured. Here are three principal methods by which this may be done: First, by means of Maxwell's discs; secondly, by Abney's colour patch apparatus; and, thirdly, by Lovibond's tintometer.

Briefly described, Maxwell's method, as utilised by Rood,* is by means of discs of stiff cardboard painted with certain pigmentary colours, and matching the luminosity or brightness by a smaller disc with black-and-white sectors, rapidly rotating them till they appear equally bright. Although a table is given both by Rood and also an extended table by Church, they are both valueless, because they only represent the luminosities of the actual samples tested by them.

Abney's method is fairly well known, and consists in the use of a source of light, a shadow rod, and rotating sectors. The rod is placed at some distance from the pigment to be measured, a white surface being also placed by the side of the pigment; a shadow of the rod is cast by direct light on to the white surface, and by a silvered mirror a second shadow of the rod is cast on the coloured surface. The aperture of the sectors is now altered whilst rotating till the two shadows are equally luminous. A white surface is now measured, and the mean of the angular apertures gives the relative value of the two luminosities.

Lovibond's tintometer I am not so well acquainted with for measuring the luminosity of colours; but, as I have found it extremely useful for my private work in connexion with colour, I am sure it would answer for this also. This instrument was exhibited at the Photographic Club one night, and, if I remember rightly, it was stated by Mr. E. J. Wall, who showed it, that the luminosity of a colour could be determined by seeing how many neutral tint glasses were required to totally extinguish all sense of colour. If this is so, it seems to me to be the most convenient, because the simplest, method of measuring the luminosities, for the instrument for other work is extremely simple.

There is another important point in connexion with pigmentary colours, and that is the form in which they are used. Every one is aware of the great difference between oil and water colours when laid on canvas or paper; the former presents a much more saturated appearance than the latter, these, as a rule, being mixed with a considerable amount of white light from the underlying support of white paper, and this is still more marked with pastels. The purity of the colour then must be taken into account, for it is a well-known fact that, the more white light is mixed with a colour, the less marked a colour is, and we have only to mix sufficient white light with any colour to destroy it as colour altogether.

Possibly, because of this admixture of white light, which is so difficult to eliminate with pigments in the shape of either water or oil colours, it would be worth while to use materials such as velvet, wool, and cotton. Pure silk velvet, from its method of manufacture, as all know, presents only the ends of the fibres to the eye, with the result that the colours reflected from it are more nearly pure, that is, unadulterated with white light than from almost anything else; wool, on the other hand, reflects more white light than velvet because of the fibres being presented sideways to the eye, whilst cotton, from the peculiar non-transparent nature of the fibre, shows considerably less colour and also more white light admixture.

Turning now from pigmentary to spectrum colours, it seems to me in face of the years of experimenting by such men as Eder, Vogel, Abney Schumann, Bothamley, &c., that further tests are not required; but, assuming that they are, it would be by no means difficult to arrange a photo-spectroscope so as to obtain easily comparable results, for, having once focussed the spectrum for its whole length from the red to the violet on a plate, one could ensure a constant light, constant in so far that the errors would be spread equally of two consecutive exposures, by using either the incandescent gas of a given weight of magnesium ribbon; and, with a micrometer scale photographed on each plate, it would be quite possible to determine the sensitiveness of an ordinary and an isochromatic plate with identical exposures.

But, supposing we throw over the spectrum, on the plea that in nature we do not, as was once said, "have a spectrum hanging on every tree," a test could be easily arranged which ought to satisfy all. A sheet of wire gauze, about two feet square, could be rigged up in a picture frame, and various flowers stuck in the meshes, which would fairly include most, or at least the principal colours met with in nature. For instance, in the pansies we could find any range of purples, violets, and blues; in the rose, any range of reds; whilst in the pansies and chrysanthemums, any range of yellows might be found; whilst, for greens, there is a large variety of foliage to choose from.

For such a test as this a stereoscopic camera, with identical lenses, should be used; and, if any difficulty was found in obtaining colour-sensitive and ordinary plates of precisely the same speeds, this might be adjusted by variation in lens apertures.

Till this subject is fought out and settled once again on purely definite lines, we shall, I suppose, be still at times treated to the echolalian babble of scribblers.

PHAROS.

* *American Journal of Science and Art*, February, 1878.

BY THE WAY.

I SHOULD not again have referred to the matter of professional *versus* amateur that engaged me last month had I not gathered, from further correspondence that has reached me, that I have not made quite clear the ground I take. It seems that most of my correspondents—who by the way, are not quite so "down" on me as previous ones—imagine that I want to back up the trading amateur or "shamateur" as I called him. Far from it. All that I have said or can say that can be in any way construed as in his favour is that, whatever he may do in the way of interfering with the professional, there is no legal remedy for it. Professionals may combine in their own interests, but I really cannot see how they are to stop the pest unless they are willing to agree to a rigidly enforced tax upon photographs. That seems to me the only way to get at the evil, but I fancy the remedy would be worse than the disease.

I gather from my recent correspondence that professionals generally agree with me that the real amateur is out of the discussion altogether, and a very reasonable letter from Mr. Archibald Robertson, of Glasgow, whose name has been familiar to me for very many years, sufficiently clearly states the case from that point of view. He complains that I do not say who I am or what gives me "a position in the discussion," to which I can only reply that, as I started the discussion, I must necessarily have a position in it, and as to who I *am* for all the purposes of the discussion he has only to refer to the signature at foot. But, when he says that a better name for me would be "Dog-in-the-manger," he is not only unkind, but scarcely reasonable. However, that I can forgive, and pass on to matters on which we are both in thorough accord.

He says: "I knew the amateurs thirty or more years ago as gentlemen in every sense of the word—merchants, manufacturers, men of education, ministers, professors, &c., and there are, doubtless, many and more of them now. That kind were true amateurs, and no one need have any word but praise for them. But my experience and observation of the more recent so-called amateur photographer is that he turns it in every possible way to his own advantage, and very often directly to the disadvantage of the professional. So I call these parties *false* amateurs because they have other strings to their bow, and are taking the trade that should go to the tradesman." Now, I ask, could any one more exactly state my own expressed views than the above *verbatim* quotation?

I will pass on to another phase of the question on which Mr. Robertson and I pretty well agree; he says: "Then we have the same spirit in the dealers. The time was, when any person called at their shop to speak about a copy, enlargement, or taking a view, they would recommend one or two houses—perhaps send their boy round with them. How is it now? 'We do all kinds of work from developing to painting.' And if the picture turns out pretty well, and the 'push-the-button-man' has a handle to his name, then a fine placard is placed in the window, 'This photograph was taken by ———, who used one of our "Magnificent" cameras. Dear sir, looking round it is very like falsehood and fraud, and wilful imposition. . . .' Well, with the exception of the falsehood and fraud, &c., the case is stated only too truly; but here, again, there is no very ready remedy. The dealers have a perfect right to do as they please in the matter of copies or enlargements if they choose to undertake them, and the photographer's only remedy is in the form of boycotting those who run counter to his interests; but, as I hinted last month, I don't think that will ever prove a successful process. The professional, no less than the amateur or shamateur, likes to buy in the cheapest possible market, and the dealer, in order to give the professional his materials at little over cost price, *must* trench a little on the professional's ground to make a living. I am stating but hard, dry facts, and am not interested in standing up for either "shamateur," professional, or dealer—perhaps there is something to be said for and against each of them.

But Mr. Robertson might have said something about that undoubted "fraud," the pharmaceutical chemist, who not only deals in camera lenses and photographic materials that don't in any way belong to his business, but will undertake enlarging, copying, or indeed anything that he can turn a penny by. This is the man who goes into metaphorical hysterics if a photographic dealer sells an ounce of corrosive sublimate, and, nowadays, probably could not tell you what corrosive sublimate consists of, and only knows it as one of the "scheduled" poisons. This is the sort of man who perhaps, in ninety-nine cases out of a hundred, began his apprenticeship by sweeping the shop floor and filling pints of linseed oil in the "back place," and who in the last few months of his time managed to cram sufficient *quasi* botany and materia medica to enable him to scrape through his "exam." And this is the man, forsooth, who alone claims to be legally entitled to call himself a chemist! I have known, and know, dozens of them, who are accurately described in the words I have used, though I am quite willing to admit that there are many others who are really trained and educated men, and fully entitled to be called chemists in the best sense; but, as a rule, these are not the ones who go in for, at any rate, the enlarging business.

There are, of course, throughout the country, many firms who are both *bonâ-fide* pharmaceutical chemists, and equally *bonâ-fide* photographic dealers—firms of whom it would be difficult to decide in which capacity they are better known; but these, again, are not the ones who tread upon the professional photographer's toes or steal his trade. There is nothing to prevent the pharmaceutical chemist from dealing in what he likes, from tin whistles to artificial manures, and there ought to be equally no reason why the photographic dealer should not be in a position to supply *any* photographic requisites, whether they be poisons or not. Surely to goodness, such a firm as that of William Hume, of Edinburgh, is as competent to handle poisons with safety—and, moreover, with judgment—as a little country chemist, with the shop-floor and linseed-oil antecedents! But, no, that highly scientific body, the Pharmaceutical Society, who don't like the title of "trades union," won't permit it; and, unfortunately, have the law on their side, unjust though it might be. Here both professional photographers and photographic dealers have an undoubted grievance, for both are interfered with.

Talking of country chemists, I have personally had many amusing, if annoying, instances of their vagaries. A few months ago I happened to be in a country town in the midlands, boasting five or six thousand inhabitants and two chemists' shops, in the window of one of which I saw the well-known blue pyro bottle. As I was in want of pyro, I entered, and asked for an ounce, when a youth of three or four-and-twenty, not an apprentice, and I should say not the proprietor, for he put on too much "side" for the latter, took the bottle out of the window, and disappeared behind the scenes to wrap it up. After an unconceivably long absence, he reappeared, and placed the usual neat paper parcel, duly labelled, before me. "What's this?" I asked. "I want an ounce of pyrogallic acid." "That is it, sir." He had actually taken the trouble to scoop out the contents of the bottle, which, no doubt, *he* took to be a pound. As it was the only one they had in stock, I had to take it, without, however, giving him the trouble to replace it in the bottle. "How much?" I asked—it was Schering's—and, after much reference to price-lists, as usual on such occasions, the reply came, "Four and six, please, sir!" Needless to say, I did not pay that; but I could not, with any amount of persuasion, get it below eighteen pence.

On another occasion while travelling I wanted some quinine, so I asked at the chemist's, "What's the price of quinine? I only want a small quantity, say, a drachm." Directing his eye into the corner of the ceiling with a sort of calculating look, the assistant replied, after a few moments, "Half-a-crown, Sir." "Half-a-crown an ounce? Oh, I only want a drachm." "Half-a-crown a drachm, halfpenny a grain," came the reply. "Hang it all," I said, "I can get it at two shillings an ounce in London." "Doesn't matter what you can get it for in London, that's Mr. ——'s price here, and you'll have to pay it." I explained as politely as I could under the circumstances that I really could not afford it, and at the next place I stopped, a large town, I got it at two shillings an ounce.

Good old pharmaceutical chemist! With all your faults, and though you are not generally beloved by photographers, you are sometimes very amusing to DOGBERRY.

PHOTO-MECHANICAL NOTES.

NEXT in interest to the question, Who invented the enamel process? is another, which has, no doubt, often occurred in the minds of process workers: Why use fish glue? It does seem the oddest thing conceivable, yet everybody uses it because every one says it is the thing to use. This is generally the case with photographic formulæ, and no one troubles to seek the reason why.

We have seen, according to my last article, that a variety of other substances can be used, in preference, or in conjunction with, fish glue. Prominent amongst these is gelatine; and, knowing that the process depends upon the well-known action of bichromate upon a colloid body under the influence of light, it seems strange, at first thought, that gelatine, one of the purest of the colloids, should not be used in preference to a semi-putrid chondrin like fish glue.

Gelatine certainly can be used; it can be treated in a similar way, and can be carbonised by strong heating until it is insoluble in the usual etching fluids. But gelatine has two or three disadvantages. In the first place, it solidifies when cold, and must be kept heated whilst being used for coating; secondly, it does not keep long when mixed with bichromate; and, thirdly, it cannot be developed in cold water. These disadvantages might be minimised or overcome by working under suitable conditions; for instance, by keeping the gelatine warm whilst coating, by making it up freshly, and by developing with warm water. But, granting this, it must further be urged as an objection, that gelatine does not give as sharp dots in the half-tone print as does fish glue, unless the negative is very keen in contrast. If there is the slightest tendency to raggedness in the dots on the negative, or if they are not so well joined as they might be in the high lights, there is a vignetted action on the gelatine, which makes it difficult, if not impossible, to wash out the print clean and sharp. With fish glue, it is easier to wash out, owing to its greater solubility. Vignetted action is hardly possible, because nothing very short of full exposure will allow the glue to adhere to the plate during the washing out.

It is for this reason that the idea of using carbon tissue for the half-tone process is dropped almost as soon as it is tried. It is too difficult to get clean-edged dots, and it cannot be worked with such facility and rapidity as a fish-glue solution in the hands of an expert printer. Moreover, the sensitised tissue must be in very good condition and carefully exposed, or it will be leathery, and will not

stick to the metal. I once heard the suggestion made, that a carbon tissue should be made with fish glue, but this would obviously be impossible, by reason of such a film being soluble in cold water. It would not be possible to sensitise it, nor could it be soaked previous to squeegeeing.

In this connexion, I notice that a French writer, Villain, suggests a transfer-paper process, in which the paper backing is to be destroyed in the carbonisation of the gelatine surface after it has been squeegeed down to the metal. But I feel sure such a process would present considerable difficulties in working. For instance, before the transfer was made to the metal, the image would have to be washed out until it was a mere stencil on the paper; if there was the slightest veil of gelatine between the dots or lines, it would carbonise with the image and render etching impossible. Any one who has worked either carbon tissue or photo-litho paper will know how extremely difficult it is to avoid this veil between the lines or dots, unless the negatives are of the most perfect character.

The objections which apply to processes with gelatine apply equally to any variations of the formula with ordinary glue or isinglass. It must not be forgotten, however, that it is possible to convert gelatine into meta-gelatine, in which state it loses its property of solidifying when cold. This meta-gelatine, it is generally known, can be formed by prolonged boiling, or by treatment with acids or other suitable chemicals. But, though meta-gelatine will give fair results at times, it is vested with a considerable amount of uncertainty. A meta-gelatine prepared with acid appears to retard the action of the bichromate, and does not hold well on the metal, whilst that kind produced by boiling seems to lose all its tenacity, and will hardly hold together during development. I have tried to make a permanently soluble gelatine by treating it with chloral hydrate, but it gives a starchy-looking substance of a very rotten character for forming a film, though it may do very well, as originally suggested, for mounting purposes. Looking at the matter all round I think it must be admitted that gelatine and ordinary glue, however treated or applied, are not advantageous substitutes for fish glue.

Among departures from the beaten track may be mentioned the use of lichen starch, such as Iceland or Caragheen moss, which, when boiled with water, forms a jelly, and may be utilised in conjunction with fish glue to give the latter a little more body. Vegetable products offer a more promising field for investigation in respect to this process than do gelatines and glues, the starchy and albuminous matter forming glutinous substances which seem suited to the purpose. One of the most likely things which occurred to me was an extract from linseed, somewhat akin to linseed mucilage; but, though it printed rapidly and washed out well, there were other troubles which rendered it unfitted for use in this process. It not only gelatinised when cold, but it became insoluble, and the more one tried by heating to melt it the more insoluble it became, as if the heat, in conjunction with some property in the stuff itself, caused the bichromate to act without the aid of light action.

Another substance I have heard of as being used, is a size extracted from Scotch seaweed. Of this I have no experience, but agar-agar, a kind of gum extracted from a seaweed found in Ceylon, was one of my trial substances. It, however, decomposed when heated to the necessary degree for forming an enamel.

With gums several practical processes have been evolved, and, as I pointed out in my last article, the original burning-in process was founded on a gum film, and to this day gum is used in preference to fish glue by many of the best American workers, who claim that it washes out more readily, and so gives sharper work, whilst at the same time forming a harder resist. The gum formula, however, requires a good deal of experience before it is manageable. To begin with, unless the very finest picked gum acacia is selected, the film formed by the gum solution will be difficult to develop, and will probably crack in drying or in the burning in.

It would seem that what is wanted for this process is a gum that is rich in arabin, which constitutes the most soluble portion of the gum, being, in fact, soluble in its own weight of water. As this arabin may be precipitated from its aqueous solution by alcohol, it is easy to get it even from an adulterated sample of gum acacia or gum arabic.

Some workers add albumen to the gum; it is claimed that this prevents the film cracking. This is intelligible only on the assumption that the albumen in such case is not in solution, but simply in a fine state of subdivision, which gives a slight granularity to the film. It may have been remarked that the addition of a little very finely ground lamp-black or Indian ink to the sensitive solution, whether of gum or fish glue, greatly aids the adhesiveness of the image to the zinc during the etching, and I take it that the albumen in either the gum or the fish glue has much the same action. It really breaks up the continuity of the glue film into a sort of network, so that there is less "filminess," so to speak, and therefore less liability to peel off. I think Mr. W. B. Bolton remarked the same thing, in writing on the *Carbon Process without Transfer*, some time ago in this JOURNAL, the pigment in the gelatine being a distinct advantage apart from its property of colouring.

In practice, it is found that a fish-glue solution which contains albumen gives a film which does not swell up in the washing out; it holds together better, and so permits more washing being given to develop sharper dots.

It has been suggested to add to the glue a resin made water-soluble by digesting with a caustic alkali. I have had no experience of this, but I hardly think a perfect mixture would be secured. An addition more likely to be successful would be the so-called "water varnish," made by boiling white lac with borax and carbonate of soda. It would, however, have to be well filtered, as it gives a good deal of sediment.

Another idea is to add finely powdered bitumen to the glue solution until an emulsion is formed, but I don't think the individual who suggested it ever carried it beyond the stage of a mere idea.

The addition of sugar to the solution, though often suggested, is an unnecessary elaboration and of doubtful advantage. It may also tend to make the film hygroscopic, so that in damp weather the trouble of the plate sticking to the negative may be experienced.

The keeping of the glue is a matter that should be carefully studied. Although it is preserved with a strong antiseptic, which I believe is essential oil of wintergreen, there is no doubt it undergoes changes in the degree of viscidity and cohesiveness, especially in hot weather. The former can be corrected by testing with hydrometer, and adding more or less water when making up the solution, and the latter by the addition of one grain of pure chromic acid per ounce of the whole solution, or a similar quantity of chrome alum.

A solution when made up seems to work best after standing a day or two in an open vessel, and Turati, who has investigated the subject, believes that a tendency towards putrescence is an advantage rather than otherwise. He suggests the addition of a little of a known putrescent sample to a fresh solution.

One hears a good deal about the acidity of the glue being accountable for faults in working, but I have never found it so. The cause for the troubles must be looked for in other directions. It is a common practice to add ammonia to the solution; but, if this is done in excess, it destroys the cohesiveness of the glue and tends to promote putrescence too rapidly.

Taking it all round, fish glue only needs proper handling—which is more a matter of experience than anything else—to secure as fine or finer results than can be obtained by any other medium.

WILLIAM GAMBLE.

WASHING PRINTS.

THEORY says that silver chloride is entirely soluble in a solution of hyposulphite of soda, with the formation of a hyposulphite of silver soluble in water, consequently the removal of these salts from our prints should be a very easy matter. Practice says this removal in its entirety is very difficult to achieve, and Messrs. Haddon and Grundy, whose interesting and careful experiments in this direction are so much appreciated, conclude the entire removal of silver from the lights of the prints is impossible, if the prints are to be left uninjured; moreover, the amount left is, under favourable conditions, sufficient to degrade the lights, and so ruin the print. Mr. Watmough Webster, in a recent article in this JOURNAL, goes carefully through the whole matter, but does not state if he can ensure the production of un-

changeable silver prints, although he has some that have stood the test for a good many years.

To all intents and purposes, not only one, but many silver prints have been made permanent, and it is said that a thing to be repeated *must* conform to some rule or other, or it could not be repeated; therefore, as practically permanent silver prints have been made many times, there is a rule, if we only knew what it was, to ensure the permanency and beauty of all our work. Now, the only conclusions we can draw are, that either the silver salt exists in a state unaffected by exposure to light and air, or is absent altogether in dangerous quantity from those prints that have stood the test of so many years' existence. Now, the testa of Messrs. Haddon and Grundy were made under more favourable conditions than are likely to exist when *quantities* of work have to be got through by a number of *employés*, whose chief aim is more frequently than not to get the work out of hand as expeditiously as possible. Still, if with the most scrupulous care some silver salt is left in the print sufficient to be harmful under certain conditions, less favourable ones are unlikely to improve matters. There is quite a formidable list of reasons why prints may vary in permanency, both as regards mere discoloration or actual fading, that apparently go through exactly the same processes. Suppose we enumerate some of them. Primarily, there is the negative itself, that may vary in all degrees from dense and hard to soft and delicate, from bright and crisp to flat and foggy; some that may require hours of exposure to sunshine, others that will be over-printed in a few minutes in the shade. The image formed on the paper would vary with each kind of negative; and it has been proved over and over again that thin, rapidly printing negatives produce less permanent prints than plucky, bright negatives do. This indicates the kind of negatives best adapted to produce permanent work.

Then, again, the paper may vary in quality and preparation, of which the user can know very little about, as he merely judges by results. To these two primary conditions are added the various chemical processes, and the crude or clever ways of carrying them out, each print has to undergo before it finds its ultimate resting-place in frame or folio. The proofs, being printed, are washed much or little, or not at all, in plain, salted, or alkaline waters previous to toning, which may take place immediately or hours after, during which time the prints are soaking. The toning may be of many descriptions, according to the fancy of the worker, and the time of colouring may vary from a mere dip to hours, with a corresponding variation in the amount of deposited gold. The washing before fixing may be much or little. The fixing bath may be strong or weak, the hyposulphite of soda used pure or very much adulterated. The prints may be immersed many together or singly, and remain in it for a long or short period, kept well separated or left in masses. They may be taken out of the fixing by handfuls or singly, and put to wash in the same way, the soluble matter removed quickly and thoroughly as possible, or left to soak in a smaller quantity of water without any care. The washing water may be hot or cold, and continued for a short or long period, which practically completes their preparation. The mounts and mountant have also considerable effect in the permanency for photographs, or, rather, a silver print. With all these varying conditions in the production of a print, it would be something wonderful if the results were anything like uniformly good—it would be idle to expect it.

Experience has pointed out the best lines to work on, and the certain dangers of other methods of procedure. I will not go so far as to say only one method will produce a permanent result, as many variations may be made with equally good results, but there are certain important conditions that cannot be safely neglected, and these are *thorough fixing* and *thorough* and *rapid* washing.

Thorough fixing can only take place in a *fresh* solution of good hyposulphite of soda of sufficient strength, and the washing in both cold and hot water, frequently changed, for a couple of hours. Of course, with gelatine papers, the hot water must be omitted. Washing all night, although it may be rendered imperative by the system adopted with various large producers, is undoubtedly detrimental. Prints left washing from Saturday to Monday are invariably duller than those more rapidly done. Why? is a question worth considering. There is no comparison in an albumen print for colour and clearness if rapidly washed with one that has had a long soaking. The quickly prepared one is much better all round—brighter and better in colour. Long soaking probably sows the seeds of decomposition that develop to the destruction of the print when the conditions of storage become favourable to the change.

A *weak* hyposulphite bath is, I think, wrong in principle and wrong in practice, as the silver salt is insoluble, or only partially so, in weak solutions of hyposulphite, which has been proved many times. Longer immersion of the prints will not compensate in any satisfactory manner for a stronger solution. I have before me, as I write, test prints that were specially prepared and perfect in all respects as prints when they were made and fixed in two baths of weak hyposulphite. In eighteen months they began to show yellow patches, and were very yellow in two years after preparation. It is now about eight years, and they have suffered little alteration since then. The sky and delicate shadows have somewhat faded, but the prints are tolerably bright otherwise. Prints fixed in strong baths at the same period, and treated in the same manner, are quite unchanged, the only difference being the strength of the fixing solution. During the past thirty years I have made repeated trials, the advantage always being with those treated with the strong baths, and, I may add, short but thorough washing afterwards.

EDWARD DUNMORE.

OUTSIDE STUDIO WORK.—IV.

IN a previous article I referred to the difficulty experienced in the photographing of horses at close quarters when such were moving rapidly across the field of view.

When dealing with such in a position at rest or free from motion, but little difficulty will be found in securing them steady, provided some suitable stratagem be employed to attract their attention just at the moment of exposure. Of course, some animals will be found that are more fractious than others, but an attendant who is well conversant with the characteristics of a horse will well know how to coax or deal with him in many respects outside the ken of those unacquainted with the habits of such. As a rule, it will be found that much will depend on the selection of a suitable place to photograph them at, and, in some respects, horses are like human beings, *i.e.*, they have their good and bad points, or, in other words, look better in some situations or poses than in others.

Owners may be good judges of horses, but they all have an idea of their own, that their animals look best in a certain position, and therefore, when such have to be photographed, it is wise, from a business point of view, to give effects to any little weakness that they may display in this respect, even although such may not coincide with the ideas of the photographer from an artistic point of view, for in this, like many other things in ordinary life, the old rule holds good, "that he who pays the fiddler is entitled to choose the tune."

Nevertheless, in this particular there is little doubt that it is wise to yield to these little weaknesses, for any photograph, executed in direct opposition to a desire openly expressed, is sure to prove unsatisfactory, no matter how technically perfect such may be. It is therefore good form, before beginning operations, to have a quiet chat anent the best points connected with the animal being dealt with.

This may mean the selection of a high or low standpoint for the camera. As a rule, however, a low standpoint is not a good position to select, because it is very liable to show off to disadvantage a weak back or shoulder in a horse. Nevertheless, it has its advantage at times, but in all cases it will be found best to get the opinion of the owner or those in charge as to the most advantageous position to work from.

This being decided upon, there remains merely the employment of some little stratagem whereby the animal's attention is strongly attracted just at the moment of exposure.

Some animals differ in this respect: those that are very sensitive to sound are best dealt with by blowing a shrill whistle just at the moment the cap is ready to be removed; this will, in nine cases out of ten, cause the animal to prick up his ears and look intently and earnestly just in the direction of the sound. This is the moment to expose the plate, and, when all is ready beforehand, failure to catch this excellent pose or expression seldom happens. In other cases it will be found that some horses are very keen to the attraction of sight, and, when such have to be dealt with, the better plan is to adopt some stratagem that appeals to this sense. All being in readiness in other respects, such as the animal being placed in the selected position, the shutter drawn, and the cap of the lens in hand, let an attendant stand close by the party blowing the whistle, and, at the same moment, wave violently a white handkerchief; this never fails to attract the horse's attention and yield an opportunity for exposing the plate.

Into the details of how to operate beyond the securing of the best pose of the horse, I need not enter. With the fast plates of the present day, and a lens well stopped down, work can be executed at very close quarters, by a rapid hand exposure, using a pad, not a cap, in such a brief space of time as half a second. For such rapid exposure by the hand a pad is much preferable to a cap on the

lens, thereby lessening the liability for any vibration. To some this advice may seem trivial, but any one not accustomed to the use of a pad when exposing can form but a poor idea of the speed such permits an operator to work at.

Such are among a few of the points necessary to be observed when dealing with animals.

In outside working, there are many other subjects that offer considerable trouble when they come to be actually dealt with, but which, until then, would appear to offer no great difficulty in accomplishing. Among such may be mentioned the photographing of tall spires, or high houses, where such can only be dealt with from the level ground in close proximity to such.

To many this may appear a very easy operation, but it is just about as trying a bit of work as ever falls to the lot of an outside operator, provided the same has to be executed in the daytime, when any bustle or stir in the way of street traffic is present. At least, I know from experience that I dread this class of subject more than any other that falls to my lot. To execute such from a high standpoint, or from the top of neighbouring houses, is a matter of considerable ease, even supposing such entails the climbing upon the roofs of houses, for, once the camera is up and in a position, the remainder is easy, and one has peace to work at from his isolated position, but the trouble of working from the street level is very great indeed, and, in some instances, insuperable.

First, there is the ever-moving crowd of vehicles and pedestrians, in all sorts of positions and distances from the camera, and, when such are taken into consideration, in conjunction with the use of the swing back of the camera to bring the spire or top of the building into the field of view, and the necessity, therefore, of stopping the lens well down to gain sharpness at all points on the plate, we have a combination of circumstances that is, indeed, very difficult to deal with. This class of work requires the use of a good shutter, and a small stop and a shutter exposure in confined situations are conditions entirely opposed to good results, no matter how rapid the plate may be.

In work of this kind hardly two subjects will be found alike. In cases where it is possible to get at a reasonable distance from the main object, the difficulty is not so great, because it permits of the camera being used without the same being tilted up in front, a wide-angle lens and the rising front of the camera being in such instances all that is needed to get the view on the plate, and this permits of the swing back being dispensed with; but, in cases where such has to be undertaken at such close quarters as makes it imperative to tilt the camera and use the swing back, a small stop must be employed to gain sharpness.

The best advice I can offer, under such circumstances, is to obtain the use of a covered van or other vehicle where any one can operate outside the view of the prying public, and, having placed the same at the spot selected as the most suitable, proceed quietly to rig up the camera inside on some convenient stand unknown to any one passing along, and then patiently wait until the view contains no obtruding vehicle or pedestrian; but, even with all this, the work is one that is attended with great difficulty, and hence the desire on the part of most outside operators to undertake the same very early in the morning, before any stir or bustle is afoot, or at such other special times when such traffic is at its minimum.

In quiet, outside places, where there is but little traffic, of course the difficulties are not nearly so great, although but few places will be found even in small villages, where there are no idlers present. In such cases the services of an assistant and one or two friends sent out and posted at the most convenient points in front of the camera, so as to arrest and attract the attention of any passer-by just at the moment of exposure, will prove of immense service in getting over the trouble of people walking across the field of view just at the critical moment.

The difficulty lies, as I have said, in crowded thoroughfares, when working at close quarters from the street level, and at times these troubles are well-nigh insuperable.

On occasions advantage may be taken of some alterations going on to neighbouring houses, or, in cases where stages are rigged up in suitable positions, to important edifices, but it is only resident photographers, as a rule, that are able to take advantage of such opportunities. When such occur, they should never be ignored, for they are a great benefit, and often permit of results being obtained that otherwise would never be secured. T. N. Armstrong.

THE PHOTOGRAPHY OF THE FUTURE.

[Photographisches Archiv.]

Colour Photography by a New Method.—Joly's method is based upon the following procedure. A screen, ruled alternately with red, yellow, and blue lines, is placed in front of a bromide plate. The plate is developed and fixed in the usual way, and a glass positive is produced from it. If this is laid correctly upon the coloured screen, so that the lines exposed through the red again come under the red lines, a picture in natural colours is seen. By this means we obtain by a single exposure that which in three-colour printing is only obtained by three consecutive exposures.

This process may be modified in the following manner. In process work the shape of the stop plays an important part. Every space in a Levy screen acts as a pinhole camera, and forms a picture of the lens stop. If we use a square stop, the dots in the negative are square; if the stop is triangular, the dots are triangular. If we use a stop with several openings, and the screen is properly placed, we do not get as many dots as there are spaces in the screen, but as many times more as there are openings in the stop. For the new heliochromic process a stop with three openings should be used. The first is covered with a film of blue gelatine, the second with yellow, and the third with red. Each of the triple dots of the process negative will therefore be obtained by blue, yellow, and red light. As blue light is more active than yellow and red, the corresponding aperture in the stop must be smaller than the others.

The negative obtained in this way is quite similar in principle to Joly's. But how can the positive so obtained be translated into colour?

The analogy with Joly's method, however, again applies. A dotted screen with red, yellow, and blue dots may be made to correspond with the positive, and the correct position of these dots may be determined by making the exposures through the red, through the blue, and through the yellow aperture of the stop successively.

Another process of reproducing the colours can be based upon the projection of the picture through the screen and the three-coloured stop.

A New Theory of Light (?)—It is known that light is an undulatory motion, but it is not known in what manner the chemical process gives impulse to this undulatory motion, as, for instance, in a flame-emitting light. The comparison with a string set in motion by a blow, or with waves produced on the surface of water by a stone, is, perhaps, sufficient for schoolboys, but it is insufficient for optics in its higher aspects.

In a treatise "Concerning Some Properties of Jellies," R. E. Liesegang speaks of "rhythmic reactions" [see *Naturwissensch. Wochenschrift*, 1896, p. 353]. He permits, for instance, a drop of an aqueous solution of silver nitrate to fall upon a stiffened solution of gelatine that has not yet dried. The salt penetrates the mass, and its gradual progress can be recognised by a clouded circle, which is produced by the chemical combination of the silver nitrate with the traces of impurities in the gelatine. If this cloudy appearance is examined with the microscope, it is found to consist of extremely fine dull lines, placed concentrically round the drop. These are interrupted by equally fine clear lines. The dull lines, which Liesegang, for want of a scientific name, calls "A lines," succeed each other at equal intervals. In the space of a millimetre their number is about ten. Similar structures may be obtained with other salts. For instance, the A lines form very beautifully if a very strong solution of silver nitrate is allowed to penetrate a gelatinous jelly, to which has been added a very small quantity of ammonium bichromate.

Whence come these lines? Perhaps we may infer from them that the chemical process is not continuous, as hitherto accepted, but that it takes place rhythmically. Perhaps all chemical action proceeds rhythmically.

In a jelly the rhythm is proportionately very slow, as the reaction proceeds slowly. In burning a gas, the supposed rhythm may be so quick that it produces the undulations of light. Water may have a retarding action in chemical processes occurring in aqueous solutions, but less than in jelly. Consequently from the slower rhythm the somewhat larger undulations of radiant heat are produced. Auriman.

DYES AND PIGMENTS IN PRACTICAL PHOTOGRAPHY.

III.

Photographic Ray Filters.—Even colourless glass may in time acquire a distinct power of selective absorption of light rays. This property, which has been long known, is supposed to be due to the fact that glass-makers, in order to produce colourless glass, were in the habit of adding a small quantity of peroxide of manganese (glass-maker's soap) for the purpose of correcting the slight greenish colour caused by the presence of traces of protoxide of iron. The pink colour imparted by the manganese being complementary to the green colour of the iron oxide, the result was a complete neutralisation of colours by each other. Unfortunately, both manganese and iron compounds are very sensitive to light, and the equilibrium so delicately adjusted by the glass-maker is soon disturbed by prolonged exposure to light, with a consequent reappearance either of a yellowish or pinkish hue. The elaborate experiments of Gaffield, communicated to the British Association in 1872, established the fact that the change in all cases leads to a deepening of tone, so that the result is always an acquisition and never a loss of colour. Many of the glass-makers have now given

up the practice of using manganese, and oxidise the ferrous oxide to the almost invisible ferric compound by the addition of arsenious oxide. There is no doubt, however, that photographers have in the past suffered seriously from this practice, even optical glass not being always exempt from a distinct tendency to become yellowish in sunlight. The presence of a slight trace of lead is said to prevent this change.

When we come to consider the colours of non-actinic glass as used for dark-room illumination, it is necessary to remember that there are two distinct methods of imparting colour to glass, viz., either by adding the colouring principle to the molten mass, as in pot-metal, or by merely giving a superficial coating, as in flashed glass. The two varieties are at once distinguishable on looking edgeways through a small piece of coloured glass. Ruby glass is always flashed, for otherwise the colour would be so deep as to be almost opaque. Cuprous oxide is the usual colouring matter employed for ruby glass for photographic use, but gold-purple also produces a ruby tint. The absorptive power of commercial ruby glass varies so considerably that no sample, however deep the colour, should be considered safe without either a spectroscopic examination or a preliminary trial with a partly shaded sensitive film. The spectrum of ruby glass should show no trace of green, but some specimens are so inferior that even blue rays are freely transmitted. This is notably the case with ruby glass coloured with gold-purple. Green glass is generally pot-metal, and the colour is imparted by a mixture of cuprous and ferrous sulphates. In these days of colour-sensitive films, it is difficult to say what is absolutely safe; but, if a combination of ruby copper glass with either cobalt or green be used, as recommended by Abney, there will be very little danger of fogging even with the most sensitive films.

Photographers often have occasion to use substitutes for coloured glass, in the shape of dyed papers and fabrics. The danger of many of these substances bleaching in the light is already too well known to need more than a passing caution. The properties of some of the colouring materials which have been used for this purpose are given in the accompanying table, which I cannot claim, however to be by any means complete, but is to be taken rather as an example of the properties which the photographer should examine in the selection of non-actinic colours.

Substance.	Colour.	Solubility.	Permanence.	Rays Transmitted.	Remarks.
Chrysoidine	Orange ...	Alcohol	Fugitive	Green, yellow, and some blue	An azo colour.
Fuchsine.....	Red	Water	Very fugitive	Red and some violet...	An aniline colour.
Aurin	Red	Alcohol	Fugitive	Red, yellow, green ...	A phenol colour.
Dragon's blood	Red	Alcohol, ether, and oils .	Fugitive ?	Green, orange, yellow .	A vegetable resin.
Gamboge	Yellow.....	Alcohol, naphtha	Permanent ?	Yellow.....	A vegetable gum.
Brazil wood	Deep yellow	Hot water, alcohol ether	Fugitive	Yellow, red, green.....	Becomes scarlet with potash.
Lead chromate	Canary ...	Potash.....	Permanent	Green, yellow, and red, and some blue	Solution is orange red.
Potassium bichromate	Red	Water	Fugitive on paper	Yellow, red, and some green	Unaltered in aqueous solution.
Turmeric	Yellow.. ...	Alcohol	Fugitive ?	Red, orange, yellow, and green	
Xanthorhœa	Orange ...	Alcohol	..... ?	Orange	Makes a good transparent orange film.
Saffron	Yellow.....	Water	..... ?	Yellow, orange, and red	

Amongst the continually increasing number of red and yellow dyes, which the chemist is almost daily bringing to light, there are, doubtless, many which will prove even more useful for adiactinic purposes than those which enjoy an older claim to photographic consideration.

Coming next to the question of screens for orthochromatic photography and three-colour work, we find three distinct methods in use, viz.—

1. Coloured gelatine or collodion films.
2. Coloured glasses.
3. Liquid cells.

It will be convenient to summarise the chief advantages and drawbacks of each of these methods.

Coloured films, either of gelatine or collodion, are easy to prepare of any desired tint, but most of them are liable either to fade or lose their transparency. A simple method is to colour an ounce of amyl-acetate collodion with five grains of aurine or of "golden yellow" aniline, filter carefully, and flow on to thin plate glass. A more structureless film is said to be got by colouring benzole crystal varnish with turmeric, annatto, and kamala. In using mixtures of colours, however, care must be taken to avoid the production of black, even to a small extent, as this would involve a positive loss of light without any selective absorption at all.

The second method—the use of coloured glasses—has this great objection, that such glasses are extremely difficult to procure of uniform and suitable tint. Liquid cells, however, can be made of any desired thickness and filled with solutions which are practically unalterable in sunlight. Taking the internal width of these cells as one-eighth of an inch, we have the following formulæ for screens of different tints:—

YELLOW SCREEN.

Potassium chromate	1 part.
Water	300 parts.
Potassium hydrate.....	A trace.

VIOLET SCREEN.

Cupric chloride, concentrated solution	7 parts.
Ammonium hydrate	5 „
Water (distilled)	17 „
When filtered, add	
Methyl violet β	3 „
Fuchsin δ.....	5 „

ORANGE SCREEN.

Cobalt chloride, concentrated solution	15 parts.
5 per cent. solution ammonium bichromate .	25 „
Ammonium hydrate	3 „
Water	35 „

GREEN SCREEN.

Nickel sulphate, saturated solution.

Even liquid cells should not be filled with aurantia, primuline, or chrysoidine, on account of their tendency to alter in tone under the action of light. One great advantage of liquid cells is the ease with which the depth of colour may be regulated by dilution to suit any length of exposure that may be required.

Dyes and Pigments for Dry Plates.—One of the simplest uses of pigments in the dry-plate process is the application of some non-actinic colour to the back of the plate to prevent halation. The qualities required in a good backing medium are, in addition to complete absorption of actinic rays, a good continuity of film and perfect optical contact with the glass. The backing should also be easily removable by a sponge before development. Innumerable pigments have been used for this purpose, one of the oldest and most efficient being burnt sienna mixed with gum and glycerine. Neither lamp-black nor burnt sienna should be used in water only, owing to the imperfect optical contact and liability to become detached in minute particles causing pinholes in the film. If used as a varnish, the removal of the pigment is difficult without the use of special solvents, such as benzole or turpentine. Spanish brown does not give a continuous film, and annatto has the disadvantage of being insoluble in water. Some of the transparent colours have been used with success, such as aniline brown, aurin, collodion, and chrysoidine varnish, the colour being allowed to remain, if necessary, to give greater printing density to the negative.

The inconvenience of plate-backing speedily led to an attempt to prevent halation by film-staining. Saffron and logwood have both been found to give perfect freedom from this evil, although the sensitiveness of the film is apparently lowered by their use. Carey Lea has advocated a solution of red litmus for this purpose. He did not find the sensitiveness reduced, while the colour turns blue

and washes out during alkaline development. He likewise found that an alcoholic solution of coralline was beneficial with collodion emulsion plates. Pigment has also been applied to the plate as a coloured substratum beneath the sensitive film, but it is somewhat difficult to avoid the penetration of the colouring matter into the film above, with a corresponding loss of sensitiveness. This difficulty was overcome by Mr. C. F. Oakley by colouring a substratum of gelatine with a solution of potassium permanganate, which not only renders the gelatine insoluble, and therefore not liable to affect the sensitive film in contact with it, but also, being destroyed by the processes of development and fixing, is without any influence upon the printing qualitives of the negative. J. VINCENT ELSDEN.

ROYAL CORNWALL POLYTECHNIC SOCIETY.—PHOTOGRAPHIC DEPARTMENT.

REPORT OF THE JUDGES.

THE Judges again congratulate the Society on the continued success o the photographic department; although there is a falling off in some o the classes, there is a considerable increase in other sections. There are many contributors of very high merit, and well worthy of very careful attention. The greatest falling off is in landscapes, which is, in a measure, attributed to the early date in the season for the Exhibition; this has been noticed in previous years when it has occurred.

First in the catalogue is the name of Mr. J. H. Coath, of Liskeard, who is represented by a large collection of pictures, mostly of small size, of the *genre* order, which show great skill, taste, and perseverance; a very amusing series is *After the Circus*. The same artist has several animal studies. Mr. Percy Lancaster, of Tonbridge Wells, shows a goodly number of examples, but the Judges are of opinion that they are not so good in quality as other work of his that they have seen before.

In the work of Mr. H. Yeo, of Plymouth, there is a very marked improvement to former years, and to a very beautiful portrait study, *Glayds*, has been awarded a second silver medal; the subject is very tenderly treated, and does great credit to the artist. He has several other exhibits; noticeable is one, *A piece of Groundsel for Birdie*.

Mr. Fred Marsh, of Henley-on-Thames, seems to make a special study of flashlight work, which he has quite made his own, the results obtained seem to leave nothing to be desired; for his pictures, Nos. 623 to 628, take a first bronze medal; they represent the interior of smiths' shops, furnaces, &c; also noticeable are kitchens of a doss house in the east end of London. Mr. W. Norrie is represented by three frames of studies.

In the animal class, Mr. W. H. Pugh has been awarded a first bronze medal for a picture of dogs, viz., *Lady Minnie and Litter*. The whole of his pictures are of a very high order, and for technical excellence would be hard to beat.

Mr. W. J. Anckorn shows some very careful work; also Mr. J. Smith. Mrs. Annie Blake shows several frames of flower studies, which are fairly good. Mr. A. Jane, of Bodmin, sends some flower and fruit studies; one frame of flowers he calls colour photography, evidently he means it as a joke. Mr. Albert Durn sends four examples of his work. Mr. S. N. Bhedwar is represented by some of his well-known figure studies. Mr. W. M. Warneuke has been awarded a first silver medal for his charming *genre* picture, *Work and Play*. It reminds one of the work of Mr. H. P. Robinson; it is a work of very high order, and fully merits the award bestowed upon it. Messrs. S. Bolas & Co., of London, take first bronze medal for architecture interior subjects, which shows careful work. The same firm show some work by the three-colour process (collotype) which is perfect and also effective. Mr. G. Lafayette, of Glasgow, receives a first silver medal for portraiture. *The Countess of Mar and Kellie* is one of the finest. He has also several others of the same order.

Mr. C. M. Wane has been awarded a first bronze medal for instantaneous work, athletic sports, foot races; the result is perfect.

Mr. W. M. Harrison, of Falmouth, is represented by a varied selection of his work. One is a very fine autotype enlargement of His Worship the Mayor of Falmouth. Another example of his, *A Cornish Fisherman*, taken direct, is a very fine study of an old salt with a weather-beaten face. His other exhibits are very meritorious. Mr. W. J. Byrne, of Richmond, Surrey, is well to the front, as usual. His examples of home portraiture are of the highest order, and faultless in rendering and very natural, and a first silver medal is an award well earned. The same gentleman contributes some large direct portraiture of equal merit in his well-known style, also some exceedingly good examples of instantaneous photography, *The Richmond Horse Show of* 1896. His studies of children are also well worthy of attention. Messrs. J. Chaffin & Son, of Taunton, send a large collection of very good work, but do not appear so happy as in some of their subjects of previous years.

AMATEUR SECTION.

There are several exhibits in this department of hand-camera work Mr. A. J. Orchard shows some careful work, also Mr. B. Carter, but his work is somewhat at fault, the printing being a bit too inky to do justice to the negatives; also, in the same class, are examples by Mr. J. A. Gill and others, but Mr. C. F. Inston is the winner of the award in this section for twelve hand-camera pictures, which are very artistic and well selected, and of Mr. A. W. Gill, Mr. Stanley Norton, and Mrs. James Blamey; the latter is highly commended for her work. The Rev. H. B. Hare, of Frome, sends three pictures fairly good, but a little too heavy in the printing. The Judges are of opinion they would have looked better in platinotype. Mr. Edgar R. Bull sends several very fine examples of architectural photography, both interior and exterior, for which he has been awarded a second silver medal. His productions are perfect. Dr. W. Page May, of London, shows some perfect landscape work of Oriental subjects, which are soft, and brilliant, and well treated, and they came off with a second silver medal. Mr. A. Fellowa's interior of the nave, Ely Cathedral, is a fine example of interior work. Mr. H. Tonkin, of Penzance, contributes two good enlargements, which take first bronze medal. Mr. C. S. Baynton sends some good pictures of architectural work. The Rev. C. V. P. Keene is represented by some fairly good examples of enlarging. They would have been better had they been a little more brilliant. Dr. W. Page May also sends for inspection several albums of Eastern scenery, well worthy of attention.

PHOTOGRAPHIC APPLIANCE DEPARTMENT.

Messrs. Spratt Bros., of Hackney, London, exhibit a fine collection of apparatus, including cameras, tripods, printing frames, &c. Their half-plate camera is a good little instrument, and can either be used as an ordinary camera or can be converted into a stereoscopic camera; the front is so arranged that the lenses can be separated or brought closer together for near subjects as required, which is very important. Their turntable head of tripod has a locking arrangement, which can be put to use when the camera is in position, which is very important. For this camera and stand a first bronze medal has been awarded for the improvements. In tripods, they have a great improvement, viz., a self-locking arrangement, which does away with buttons, &c. The workmanship in the whole of their exhibits is of the highest order, even in their cheaper sets first-class work is predominant.

Messrs. Thorn & Hoddle, of Camberwell, London, show their new patent acetylene gas generator. The Judges have put it to a practical test, and find it works perfectly, gives a good, steady light, without further attention after it is once started. This generator is for the lantern; a second silver medal has been awarded. The Judges hope to see next year their other generator for house lighting, which will be looked forward to with interest.

FORTY-SIX YEARS OF PHOTOGRAPHY.

ABOUT sixty years ago a boy in his "teens" left the home of his fathers in Markinch, Fife, and journeyed to Edinburgh, where he served his apprenticeship as a carver and gilder. No one, even the most prophetic, then dreamed that Geo. Mackenzie would, ere many years, become one of the pioneers and fathers of photography—an art-science which was then in embryo. Young George, after working some time as a journeyman gilder, came to Paisley to be foreman to Mr. William Cross, picture-frame maker, Gauze-street. Although frame-making was his trade, the youthful aspirant spent many a leisure hour in drawing portraits in crayon. He started business on his own account as a carver and gilder at 16, High-street, but, like many another young man, George, in these his early days, had not yet found his true vocation, for, while not engaged with his business, he was always experimenting with the infant art. Even after he had drifted from making frames to making pictures so difficult was the process, that one or other of the chemicals would unaccountably go wrong, and the premises have to be closed against sitters, until by repeated experiments the "fog," to his relief and joy, cleared away. Thus he went on taking pictures of his friends for amusement, until one day a gentleman who had been often taken in the back green insisted on paying half-a-crown for his portrait—a glass "positive," and so the artist's trade began.

Daguerre in France, and Talbot in England were still alive; the former the discoverer of the process by which the so-called Daguerreotype portraits were produced, the latter the discoverer of Talbotype (or calotype) negatives from which other pictures could be produced. George kept his eyes and ears open to all that was being said and written on these very interesting topics. By-and-by he resolved to construct a lens and try to take a portrait himself.

The lens by which his first picture was taken was composed of an ordinary watch glass cemented to a piece of plate glass, the cavity thus formed being filled with water. It was a difficult matter in those days to get a lens made; there were no large works specially devoted to their manufacture as now. Mr. Mackenzie's first lens was made for him by Mr. Liddell, chemist, who had the corner shop at St. James's-place, a gentleman who took a practical interest in the new art which was then in its infancy. After the lens was made, a brass-founder had to be sought out to make the fittings for it.

In the year 1850 Mr. Mackenzie made a start as a photographer at 16, High-street, Paisley. At this time he was not only the first photographer in Paisley, but also in the West of Scotland.

A friend has kindly sent me a literary curiosity in the shape of one of Mr. Mackenzie's early circulars. It is written in copper plate and is

headed, "New Crystal Palace and Paisley Portrait Gallery," and sets forth (somewhat grandiloquently) that "there are few of the discoveries of modern science more interesting and agreeable than that of photography. By its means the lineaments of those near and dear to us are taken with almost the rapidity of thought, with inimitable fidelity and characteristic expression. From the introduction of photography down to the present time, the art has vastly improved, and now it has attained a state of perfection of which few had any idea. The improvements made have had the effect of considerably reducing the charge of production, and likenesses of those we esteem and love can be had at a rate so low as to afford no room for the plea of inability to defray the charge."

After thanking his customers for patronage received since he commenced to "take coloured photographic portraits on glass," he proceeds to intimate that he "has erected a large and commodious glass house in which he can take portraits in all seasons, sunshine or shower, thereby avoiding the many disadvantages which people were exposed to by sitting in the open air." Then follow complimentary paragraphs from *The Paisley Journal* (first published in 1853), *The Post* (a Paisley edition of a Glasgow newspaper), and *The Glasgow Gazette*, all of which have long since departed this life.

About fifteen years after he started, Mr. Mackenzie removed to more commodious premises, which he had built for himself at 5, Gilmour-street, and which he no longer designated a "Crystal Palace," but simply a "Studio." At first Mr. Mackenzie's photographs consisted of "coloured portraits on glass," or "positives," as they were called by Sir John Herschel, to distinguish them from "negatives," a name which has now become very familiar. The positives had the lights and shades as in nature, while in the negatives they are reversed. The positives were coated on the back with black varnish, and were generally placed in a cheap brass mounting and enclosed in a little book-shaped case, lined with velvet like a jewel case. Most of us possess one or more of these relics of the past, the portrait of some one "near and dear" to us. If a lady, she will be dressed in a much-beflounced skirt distended with crinoline, and a coal-scuttle bonnet on her head, and be seated beside a table on which is placed a book and a vase of flowers. If a gentleman, he will be standing beside the same table resting on it his right hand, while in his left he holds the same book, and looks altogether as uncomfortable as a student-preacher before his presbytery. The portraits were freely coloured with dry paint, any jewellery on the "sitter" receiving a plentiful supply of gold lacquer to made it conspicuous. We do not place these pictures in prominent positions, but mostly keep them stowed away in our private drawers, where we can ponder over them once in a while when nobody is looking.

The introduction of the system of taking prints from the negatives ended the reign of the positives. These prints were mounted on small cards, and were called by the French *cartes-de-visite* or visiting cards—now known as C.D.V.'s. These became immensely popular, and for many years there was a great run upon them. Albums to hold them were in brisk demand, and the question of the hour was, "Have you had your *carte* taken?" This fashion brought much work to the photographers, and more entered the field. In Paisley Mr. Mackenzie still led the way, and did a large and increasing business, the high reputation he had earned for the excellence of his productions bringing him sitters from far and near.

Mr. Mackenzie had in succession, for assistants, Mr. John Fergus, who afterwards became the famous Largs photographer, Mr. Charles Fergus, now a photographer of high standing in Greenock and Dunoon, and Mr. William Brown, who now occupies a leading place among our local photographic artists.

I recollect seeing somewhere an old advertisement by one of our earliest photographers which is worth quoting. It was prefixed by the familiar lines of Burns,—

"O wad some power the giftie gie us
To see oursel's as ithers see us;"

and the reader was informed that he might obtain this coveted privilege by appyling to "Stephen Young & Sun, Photographers, West-street, Paisley." The modern professors of this art of self revelation still work in partnership with the sun, (and are very much at his mercy too) although they do not acknowledge it so frankly as did Stephen.

The early *cartes-de-visites* were taken by what is known as the collodion wet plate system. The introduction of the dry-plate system about the year 1878 gave an immense impetus to photography, and simplified the process and lessened the labour of it (especially for outside work), so much so that amateurs began to try it, and gradually became an ever-increasing band until now they are numbered by the thousand.

About the year 1880, Mr. Mackenzie started a "Studio" in the outskirts of Edinburgh, but this venture proving unsuccessful, after a two or three years' trial he gave it up and returned to his old quarters in Paisley. There he continued to labour until the present summer, taking pictures of notable events and notable people as the years slipped away. He had been working in his chosen profession for the long period of forty-six years and time began to tell upon him, as it does upon us all. His fingers were no longer so nimble nor his steps so elastic as of yore, and on May 28 last he bade farewell to the familiar scenes of his long and well-loved labours, and retired from active life, leaving his business in the hands of Mr. J. D. Ritchie.—*Renfrewshire Gazette.*

THE AFFILIATION OF PHOTOGRAPHIC SOCIETIES' LECTURES.

In connexion with the affiliation of photographic societies, six lectures, illustrated by means of the optical lantern, will be delivered, commencing each evening at eight p.m.:—

Monday, October 5, at 12, Hanover-square, W.—*Lantern-slide Making*, by Mr. J. A. Hodges, F.R.P.S.

Tuesday, October 6, at 12, Hanover-square, W.—*Negative-making*, by Mr. Chapman Jones, F.I.C., F.C.S., F.R.P.S.

Wednesday, October 7, at the Photographic Club, Anderton's Hotel, Fleet-street, E.C.—*Pictorial Photography*, by Mr. A. Horsley Hinton.

Thursday, October 8, at 12, Hanover-square, W.—*Architectural Photography*, by Mr. H. W. Bennett, F.R.P.S.

Friday, October 9, at 12, Hanover-square, W.—*Intensification and Reduction*, by Mr. John McIntosh.

Monday, October 12, at 12, Hanover-square, W.—*Hand-camera Work*, by Mr. W. Thomas.

Admission is free to members of affiliated societies and their friends by tickets, which can be obtained from the Secretary of any affiliated society. Members of the R.P.S. can obtain tickets from R. Child Bayley, Secretary, 12, Hanover-square, W.

The lectures, with the slides, &c., illustrating them, will be placed subsequently at the disposal of affiliated societies, before which they can be read. Applications to borrow them should be made without delay, stating convenient dates.

THE CHEMISTS' EXHIBITION.

Last week an Exhibition promoted by the *British and Colonial Druggist* was held at the hall in Argyle-street, which in previous years was devoted to Hengler's Hippodrome, and most of the leading chemists' sundries and wholesale houses were represented. Now that chemists are entering more into the field of photographic supplies, one could not be surprised to find photography being represented to some extent. Messrs. Reynolds & Bransom, of Leeds, exhibited a fine outfit for X-ray work, including a four-inch coil, the so-called focus tube and the neat little actinometer, if one may term it so, made of aluminium, for testing not only the rapidity of plates but also the activity of any particular tube. The Blackfriars Photographic and Sensitising Company made a good show of portable dark rooms and developing sinks, besides the Anschütz hand and stand camera, and a new and very neat hand camera manufactured by Griffiths & Co, for whom this firm are sole agents; this hand camera, called the "Cyclist," is put up in two kinds, one at 30*s.* and the other at 50*s.*; the latter has a single lens with iris diaphragm, actuated from the outside, with time and instantaneous shutter. The plates are carried in sheaths, which are provided with projecting pins at the lower corners which travel in a slot, each plate being released in turn by lifting a spring lever on the top of the camera, the plates falling into the bottom of the camera It is simple in design, extremely neat in appearance, and very light and well suited, not only for the class after whom it is named, but for ordinary work also. Several of the wholesale firms, like Barclay & Sons, J. Sanger & Sons, also showed cameras, plates, and papers, and Messrs. Burroughs, Welcome & Co., had a goodly show, very tastily exhibited, of their photographic tabloids.

Our Editorial Table.

Der Halbtonprozess.

By "Julius Verfasser." Translated into German by Dr. G. Aarland. Wilhelm Knapp, Halle a/S.

This work, forming Vol. XXIII. of the *Encyklopädie der Photographie*, is a translation from the English. The *Practical Manual of Photo-engraving in Half-tone on Zinc or Copper* was published here in 1894, under the *nom de guerre* of "Julius Verfasser." Dr. Aarland has not only translated, but made valuable additions to the work, thus including recent practical improvements in the process and the results of the scientific investigations of the basis upon which it rests. The first part deals with the arrangement of the workrooms, screens, cameras, and other apparatus. The second part treats of the negative, the preparation and etching of the plate, &c. The treatment of the subject is clear and concise throughout, and we can recommend the work as a reliable practical exposition of the half-tone etching process.

The Photographic Worker.

By John A. Randall. Published by the Author at 42, Tonsley-hill, East hill, Wandsworth, S.W.

The central idea of this pamphlet is trades unionism and co-operation as applied to photography, and the author is animated by an apparently earnest desire to improve the lot and condition of the

photographic assistant, whose position only too frequently excites our compassion. Of such Mr. Randall has more than once pleaded the cause in our Correspondence columns, and he amplifies his advocacy in the pamphlet before us. He recommends assistants to join the National Union of Shop Assistants, 55, Chancery-lane. Union and combination are his remedies for the sufferings of his clients. Amateurs and "Polytechnic" photographers, in the opinion of our author, adversely affect the position of operators and assistants, and some hard things are said of the treatment frequently received by subordinates at the hands of their employers. Here is what he says on the subject of competition amongst employers: "Besides the unfair competition amongst workers, the competition amongst employers also brings down the rate of wages. The employers are as unorganized as the assistants, and, in consequence, they are driven to adopt a policy of cutting prices; this, of necessity, results in a reduction of profits. Directly profits fall, the employer will try to recoup himself by lowering wages, and, if the *employés* are unorganized, they have no power to resist this reduction, and are forced to submit. The average employer firmly believes that the money taken from wages is so much gained, but a greater error was never made. It would not be difficult to prove that, with very few exceptions, the employers paying the best wages are also doing the most work, and commanding the highest price for their work. Likewise, the employer who always contrives to pay a few shillings per week above what others are paying in wages will always have the pick of the labour market, and hence his work will always surpass his rivals. It would be easy to bring forward many instances of houses of business which owe their supremacy and affluence to the generous treatment of *employés;* and others where, this policy having been withdrawn, the business has declined with the leaving of old assistants. Few employers seem to think that their commercial success depends largely on their assistants; but such cannot be denied by any one who has examined with any closeness the rise and fall of commercial houses."

There are black sheep in every flock, and therefore we need not be surprised to find that some employers do not treat their assistants very well. But of what trade, profession, or calling, cannot the same be said? Hard as the lot of the photographic assistant frequently is, we are satisfied that, taken as a body, professional photographers are humane and fair dealing, and as anxious as other business men to recognise and encourage merit in their *employés*. Mr. Randall lays stress, and rightly so, on the insanitary conditions under which work sometimes has to be carried on; but, in our own pages some months ago, a charge of this nature was preferred against a photographer's establishment, to which we made it our business to pay a surprise visit, with the result that it appeared to us that the surroundings of the *employés* could not reasonably be complained of. We are in perfect sympathy with Mr. Randall's objects, and trust his efforts will result in benefiting those who deserve to be benefited, but the failure of the Photographers' Benevolent Association and other movements does not inspire us with high hopes of his success.

The Spook Ballads.

By W. Theodore Parkes. London: Simpkin, Marshall, & Co.

A two-shilling edition, in paper covers, of this collection of clever lays and ballads has just been issued. The first edition was referred to in these pages about eighteen months ago, and we are pleased to learn that the high opinion we then formed of Mr. Parkes' powers has been borne out by the favour the book has since earned. The author is known to many photographers, who, with a much wider circle, cannot but appreciate Mr. Parkes' witty verses and spirited illustrations. Most of the former are admirably fitted for recitations.

The Tropical Plate.

Gem Dry Plate Company, Willesden, N.W.

The "Tropical" plate, which is the latest introduction of the Gem Dry Plate Company, is made to withstand an abnormally high temperature of the developing solution. Some of the plates having been forwarded to us, we accordingly put their heat-resisting properties to the test. We employed solutions of varying temperatures—the maximum being 180° Fahr.—and arrived at the result that, in our hands, the films perfectly resisted a temperature of 120° without betraying the least inclination to fill, "run," or leave the glass. In special circumstances—such as those obtaining in tropical climates—where the employment of very hot water is necessary or unavoidable, the property of the Gem "Tropical" plate of remaining impervious to an exalted temperature should render it extremely useful.

Naturally, this plan of working, if adopted in ordinary circumstances, necessitates an important modification. Heat being an accelerator of chemical action, it it is obvious that, where a hot developing solution is used, one's preconceived ideas on the subject of exposure require revision. Such, in fact, was our experience in using these plates, the exposure for which had to be very greatly reduced compared with what would have been the case if a developing solution at the usual temperature had been used. The subject here suggested—that of the influence of heated developing solutions in the reduction of exposure—is probably worth following up.

The "Ideal" Sensitised Paper.

F. B. James & Co., Richmond, Surrey.

Messrs. James & Co. have sent us samples of their albumenised sensitised paper, which is said to be prepared by an entirely new process. We have tried the paper, and, so far as we were able to judge from the quantity sent us, found it yielded excellent prints.

Catalogues Received.

Bender & Co., 126, George-street, Croydon.

Enlargements by the bromide, carbon, and platinotype processes constitute, according to the list we have received, Messrs. Benders' principal productions. The prices charged appear to be reasonable.

Baker & Rouse, 375, George-street, Sidney.

The catalogue of this well-known Australasian house compares very favourably with the catalogues of the leading dealers at home, both in size and in the variety of the goods listed. Over a hundred well-printed pages are devoted to setting forth a rich stock of the very latest things in cameras, lenses, chemicals, cards, printing papers, sundries, &c. Some useful notes and hints on printing, &c., complete the catalogue which is well produced, and is, doubtless, found handy by both professional and amateur photographers in Australia.

News and Notes.

Messrs. Bender & Co., of Croydon, received at the Photographic Convention of Germany, at Trèves, last week, the first prize, silver medal, and diploma, for enlargements, finished and unfinished.

"The Avenue," a monthly illustrated magazine devoted to Education, Association, and Social Progress, will appear in October. The price will be 3*d.* The publishers are Messrs. Simpkin, Marshall, & Co.

The Photographic Club.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., on Wednesday evening, September 9, at eight o'clock. Members' Open Night.

Messrs. Percy Lund & Co., Limited, have removed their London warehouse and offices into enlarged premises at 3, Amen-corner, Paternoster-row, just opposite the passage into Stationers' Hall-court, in the heart of the old publishing centre.

We are sorry to learn that Mr. John Geddes, the old and esteemed servant of Mr. John J. Atkinson, 37, Manchester-street, Liverpool, in the capacity of traveller for over eighteen years, died on Saturday, August 22, aged forty-eight, at Liverpool.

At a photographic exhibition held at Willesden on the closing days of August, twenty-one medals were offered for competition by Messrs. Badger & Co., artist colour manufacturers, of 192, Broadhurst-gardens, West Hampstead. Commenting on the large number of medals offered, a friend writes: "I propose that a competition should be opened, awarding prizes to photographers who have had the moral courage *not* to win medals."

Messrs. R. J. Appleton & Co., of 58, Manningham-lane, Bradford, have acquired the photographic material department of Messrs. Percy Lund & Co. Messrs. Appleton state: "The stock which has thus come into our hands, combined with our own—already a very large one—makes us the holders of one of the largest stocks of photographic materials, apparatus, &c., in the country. We have also a considerable trade with the magic lantern and its several ramifications—loaning slides, supplying Brin's oxygen, &c."

The British Aluminium Company have already started the production of aluminium at their works at Foyers, and, according to *Aluminium and Electrolysis*, the quality has been found to be exceptionally good, and compares very favourably with the foreign metal hitherto sold. It will be remembered that the Company, who are now the only manufacturers of the metal in the United Kingdom, met with serious opposition when their proposal for utilising the famous falls became known. The works, however, have now been successfully started, the chief engineering feature being the water tunnel, which is 9 ft. in diameter, and is driven for half a mile through very hard rock. The pure aluminium used in the manufacture is prepared from bauxite, obtained from the Company's mines in Ireland, a factory having been erected at Larne for its production from the crude stone.

PLATES SHOULD NOT BE TOO FAST, BUT JUST FAST ENOUGH.—It is the tendency of most makers of the present day to produce gelatine dry plates of extreme rapidity, and I suppose there must be a great demand for such, owing, perhaps, to a great majority of photographic studios being situated in central positions, and thereby deprived of good daylight by obstructive buildings and dense, smoky atmosphere. Also the growing tendency to use artificial light for portraiture makes it more necessary to have a plate of great rapidity. I am sensibly aware of the great value of the extra-rapid plate to the professional photographer, but, although it enables one to produce tolerably good photographs under circumstances otherwise unfavourable, it has not improved the excellence of the results, I think, but the contrary. I mean that, as a general rule, where the slower plate can be used, the negative is of a much superior quality. An impression flashed upon a very sensitive film, however carefully developed, is never, to my mind, the same quality as the well-timed exposure. One has only to compare instantaneous photographs with those by time exposure to see the vast difference in the quality of the results. The excellence of photographs depends very much upon a correct exposure, and with the slower plate the margin is greater and therefore easier to gauge, the development is also quicker and easier, giving a more perfect value of light and shade, and a finer texture.—H. ROWLAND WHITE, in *Photographic Scraps.*

THE POSTER FAD.—One of the quaintest of the fads that remain with us is the freakish and fantastic "poster" fad. The poster fad is *sui generis.* Its sins are all absorbed for art's sweet sake, its crudities overlooked for a certain flaring originality. The men whose names go knocking the edges off the corridors of fame in poster lore are geniuses of a particularly morbid and flamboyant description. They are dabblers in colour possibilities, rioters in tint, revellers in fantasy. For the realities they have neither use nor respect. Exaggeration is their *forte,* nightmarish effects their studied theme. The most commonplace objects assume under the Mephistophelean touch of the poster artist a grotesquerie almost diabolic. When the poster artist draws a woman, she is either a mermaidish freak of femininity or a weird creature of the beauty that haunts the dreams of delirium. His men are long-limbed and herculean giants of an animal soddishness, or gnome-like monsters who scowl like the villains in the old-fashioned melodramas. Poster contrasts are sharp. The blacks and shades cut like a knife, the colours sting like a whip. Outlines are accentuated, perspectives abolished—the result a mad carnival of design, that it must be admitted is not wholly devoid of an exotic attractiveness of its own. How long this poster craze will last, who knows? Just now it is at its height. Weird dames of ancient Venice pose in lackadaisical fashion on the handbills of the magazines, Circean nudities trail their charms over the bill-boards of the theatres, mermaids of large-eyed seductiveness flaunt their sinuous torsos in announcements that flame with the merits of a new soap. Where will it all end? What will be the outcome, what its ultimate influence on normal, healthy American [and English.—EDS. *B. J. P.*] art?—*Philadelphia Call.*

USES OF HYDROFLUORIC ACID.—An important article, by Herr Carl F. Stahl, upon the commercial aspects of this chemical, recently given in the pages of the *Chemical News,* concludes by a brief account of various industrial aspects of the use of the commercial acid, and, as many of them would be available in the photographic laboratory, we give here an abstract of them: "The oldest and, up to the present time, most extensive application is for etching on glass. For this purpose it can be applied in three different ways—in the gaseous form, by suspending the articles to be etched over a mixture of fluor spar and sulphuric acid. This is the oldest way of etching, and I believe most burettes, graduated cylinders, &c., for laboratory use, are still marked in this way. If applied in gaseous form, the acid leaves the surface opaque, while the liquid acid leaves the surface smooth and transparent. For the production of an opaque surface with liquid acid many empirical formulæ are published, and every glass factory, or, rather, every etching boss, has his own secret formula. But they all aim to produce a mixture of hydrofluoric acid with a fluoride of ammonia, or potassium, or sodium, with which a number of other substances, such as sulphuric, acetic, or muriatic acids, or ammonium, or potassium sulphate, &c., are mixed; but it seems quite unnecessary." It may be noted that some years ago we gave a recipe for such a mixture or etching ink, in which sulphate of baryta was used, and we found it a very useful opaque etching material, the baryta giving it a body enabling it to be used with a quill pen, subserving, in fact, the same uses as a gum added to ordinary black writing ink. It appears that lead glass only requires an acid of half the strength desirable for a lime glass, and needs less time than to do the necessary work. It is further pointed out in the article that it is important that the article to be etched and the etching fluid should be at a temperature of about 50° C.—*English Mechanic.*

THE DISCOVERER OF ZINC ETCHING.—But few of the readers of this journal (*The American Art Printer*) know that photo-zinc etching and photo-lithography, in so very many ways the same thing, were invented by two different men at almost the same time, the one being in England, the other nearly on the opposide side of the globe, in Melbourne, Australia. It was in the year 1859 that Mr. Osborn, of the Survey Department of Australia, sent a young man to England to confer with Sir Henry James about the new Australian method of reproducing and making printing plates for publication. Sir Henry James was surprised that the method was so very much like his own invention, which he made (nearly) by accident, and he showed the young man some very good prints, and told him the story of how he came to invent this great medium of modern reproduction. According to a book on zinc etching, published in 1862, by A. D. C. Scott, Sir Henry James was visiting friends at Ryde, on the Isle of Wight, and made the acquaintance of a young lady artist who had great skill and talent in copper etching. She mentioned to Sir Henry James that it would be of great advantage to the public if there could be a way of producing art subjects in a cheaper manner than that of copper etching or steel engraving. That idea roused in Sir Henry James the desire of finding some means of duplicating the etching made originally by the artist, so that prints might be obtained in quantity. After trying several methods of fixing a picture on a metal plate, he tried to make a print on chrome carbon paper, which process was used at that time (1859) in photography. He prepared the paper, printed a picture on it, then inked it in and developed it, and obtained a very nice copy, which he transferred to a sheet of zinc. He further prepared and etched it, and his pleasure knew no bounds at the satisfactory result he attained in etching his plate deep enough to print many thousand copies from it. He began to improve his method day by day, and in a short time he found himself over-worked on reproducing old manuscripts and masterpieces of ancient art. Handwriting of Edward I. and the Great Doomsday Book, written in the year 1086, at Winchester, were among the first great works of reproduction by this invention. Day after day new treasures of art of long-forgotten masters, authors, and celebrities came to light, and brought refinement and education to mankind.

THE CUSTOMER TO BLAME.—It seems strange to us that that the photo-engraving trade should be in its present condition in this day of pictorial advertising, ten cent magazines which are hardly to be classed as anything else than picture books, which are bought to be looked at, not read—when the "dailies" bring out their supplements of half-tones in black and in colour, and their articles illustrated with line cuts, not to speak of the three or four-column cartoon. The amount of illustrating is constantly on the increase, and the trade is rapidly becoming a money-losing occupation instead of a bread-winner, that is, of course, for the heads of the concerns. The *outsider* asks, "How is that possible? The demand for photo-engravings is enormous. Why, even the cheap novels have their ornamented covers and their half-tone text illustrations," but the *insider* (the conscientious one), who has his eyes and his ears open, can tell you in a few words. But the easiest way to teach is by illustration and a little simple mathematics often settles a heated and long dispute. What constitutes the cost of a plate? Let us go somewhat irregularly into the process of manufacture so as to bring the vital point at the end. There is the cost of metal and wood for blocking and the cost of the blocking. There is the polishing of the metal, the coating and preparing it for the print. There is the making of the negative and the coating and turning. There is rent to pay and there are bills for light and heat. There are the wages of the errand boy too; but let us admit that, in the case of all the engraviogs plants, these items are the same, that is, of course, proportionate to the size of the plant; but there is one other item in the cost of the plate, and that is the point. The hand engraver, the finisher, is really the man who determines the value of the finished plate; and that is where the unscrupulous manufacturer has his conscientious brother at a disadvantage, for here it is that the customer gets his money's worth, or does not, as the case may be. I do not believe that there is any trade in the world where such really underhand and deceptive practices are employed to gain trade as in this one. There is a large order in the market. Mr. Photo-Engraver wishes to see the man who has the placing of it. "Let me only make you a sample plate. If it is not A1, you do not have to pay for it." The guileless editor falls into the trap with eyes wide open. The sample plate is finished, finished as it should be. Editor delighted. Price way under what any of the respectable houses could possibly touch it for. The whole order is placed, then comes the awakening. Half-finished plates—which for some unaccountable reason don't seem to print in the steam press just like the proofs which came with the cuts. If the customer had only held those "proofs" up to the light in the right direction, he might have seen some 'cute-like little pencil marks on them, but he didn't, his presses were waiting, and the engraver had delayed the work until the last possible moment. "Well, it's too late to have new cuts made now, so we will have to do the best we can, but photo-engravers are all cheats," &c. That's what the customer thinks, and with some justification, but why didn't he become suspicious when his photo-engraver offered to do the work two cents per square inch, face measurement, cheaper than Smith, who had always been doing the work before, and, besides, gave twelve proofs of each cut instead of two as Smith had been in the habit of giving—in fact, promises everything, and then keeps none of his promises, that is, no more than just keeping inside the law? Now, this photo-engraver had to pay rent, make negatives, polish his metal, buy his wood, and pay his errand boy, but he didn't finish his cuts as he should have; he deprived his conscientious fellow tradesman of his work, made no profit out of it himself, and damned the trade in general. But, in reality, it's the customer's fault, his desire for a "bargain" causes the whole trouble.—*Practical Process Worker.*

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK

September	Name of Society.	Subject.
7.....	North Middlesex	Informal Meeting.
8.....	Hackney	Discussion on Exhibitions.
9.....	Photographic Club	Members' Open Night.
10...	London and Provincial	*The Acetylene Light.* C. Hoddle.
12.....	Ashton-under-Lyne.....	Excursion: Warwick and Kenilworth. Leader, Dr. Hamilton.
12.....	Borough Polytechnic	Excursion: New Southgate and Hadley Woods.
12	Darwen	Excursion: Wilpshire to Ribchester. Leader, James Cavis.
12.....	Gospel Oak	Excursion: Whitchurch and Stanmore.
12.....	Leytonstone	Excursion: Woolwich. Leader, F. W. Wates.
12.....	South London	Excursion: Lambeth Palace. Leader, F. W. Edwards.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

AUGUST 27,—Mr. W. D. Welford in the chair.

Mr. ASHBY opened a discussion on the advantages and disadvantages of combined toning and fixing baths. His efforts with a particular formula had resulted in failure. He had first washed the prints.

The CHAIRMAN said it was not the rule to wash the prints first when using combined baths. He thought combined baths gave more uniform tones than separate baths.

Mr. BECKETT had never had a combined bath that would not tone. He considered them much quicker, of less trouble, and the whites were better. It generally took him from about fifteen to twenty minutes to tone a print in this way.

The CHAIRMAN referred to some instructions for use with a certain paper which recommended twenty minutes for fixing in the case of separate solutions, but with combined baths where it fixed first, if at the end of ten minutes the tone was what was required, it could be removed from the bath. How was it that fixation took shorter time in one case than another?

Mr. HADDON believed the ratio of hypo to water was different in the combined and the separate baths.

Mr. BANKS did not find combined baths work well with the modern printing-out papers, as they were too lightly silvered. In olden days the silver bath was much stronger, and he had a number of prints, done thirty years ago, quite good now. He had worked with hypo and alum, hypo and lead, and hypo and iron, and had got good tones, but they were not lasting.

A proposition was carried to organize a competition for the best four prints of London subjects taken within the postal district, the Judges (three in number) to be non-members.

PHOTOGRAPHIC CLUB.

AUGUST 26,—Mr. R. Child Bayley in the chair.

The HON. SECRETARY announced that the date of the annual outing to the Bull and Bush at Hampstead was fixed for Saturday, September 19.

Mr. Nesbit showed some hand-camera pictures made by himself, and others were shown which had been made by Mr. and Mrs. Welford in Cumberland.

Mr. Fry showed a slide and two developed plates to illustrate the fogging action which took place when plates were left in the slides for any length of time. The slide belonged to Mr. Hodd, and some discussion had taken place at a previous meeting as to the probable cause of the fogging action. There was a consensus of opinion amongst the members present that it was an unwise proceeding to leave unexposed plates in slides. Some instances were given, however, in which plates, allowed to remain in slides for nearly twelve months, had proved to be in sound condition. In the case of travellers, who were bound to leave their plates in the dark slides for uncertain periods, the safest course to pursue would be to test the slides for fogging qualities before trusting to them.

A discussion then took place upon the subject of

THE BEST BASIS FOR JUDGING AT PHOTOGRAPHIC EXHIBITIONS.

A member said that he thought the worst method was that which was now generally in force, viz., the collaboration of "artists" (painters) and "technical" photographers. The time had now passed when medals had a distinct commercial value, and he thought, with that value gone, the system of medal awards might go also.

Another member said that there always remained the difficulty of providing an incentive to exhibit. If there were no medals, why should photographers exhibit at all? He had found the medal system a distinct incentive, and all other systems were more or less failures.

A visitor said that he thought the public were the real judges. Let the visiting public vote for the pictures they preferred.

Other members pointed out that this method was open to grave frauds. An exhibitor might secure the attendance of a large number of friendly visitors, but a cynical member suggested that his friends might not vote as desired.

Another member pointed out that, even at exhibitions where no medals are awarded, yet a system obtains which amounts to an award, viz., the pictures have to pass a committee of selection.

The CHAIRMAN said he could hardly sum up the discussion, as but little had been said upon the actual subject itself, which was, "The *basis* upon which photographic exhibitions should be judged."

Hackney Photographic Society.—August 25, Mr. R. Beckett presiding.—Reports on excursion matters, &c., having been rendered, and other matters disposed of, representatives of the Cresco Fylma Company gave a demonstration of the various specialities of the firm. The principal of these was the Cresco Fylma uranium intensifier. Special advantages were claimed for this in that it did not clog, and the intensified image resisted twenty-four hours' washing without fading. The demonstrator showed that it offered great facilities for local intensification, and reduction also. It was also capable of producing fine brown tones on bromide paper and transparencies. Specimens of work done on Argura paper were shown. This is a gelatino-chloride emulsion on Whatman rough paper. Samples were distributed for trial. Examples of work done by the Cresco Fylma enlarging powder were also exhibited.

North Middlesex Photographic Society.—August 24, Mr. Pither in the chair.—Mr. C. M. Hamm was proposed as a member of the Society. Mr. C. BEADLE then proceeded with his lecture on

ENLARGED NEGATIVES BY MEANS OF CARBON TRANSPARENCIES.

He said that by this process it was possible to enlarge from either hard or soft negatives. A soft carbon transparency was required, and this could be got from a hard negative by taking advantage of the elasticity of the carbon process. He recommended for sensitising the tissue 4 ounces of bichromate to 2 quarts of water, and with addition of 80 or 90 minims of ammonia. For soft negatives a 1¼ per cent. solution of bichromate should be used. He also recommended, as a support for the transparency, pot or flashed opal glass, which gave very even lighting during the subsequent enlargement. For preparing the surface of the glass, 60 grains of gelatine to 4 ounces of water, and enough bichromate to give a pale lemon colour, or soaking in a solution of 3 or 4 grammes of chrome alum to the ounce after coating. He showed all the various processes, and developed several transparencies, and showed a home made enlarging apparatus in the shape of an oblong box, with which he made all his enlargements. He recommended as an easier way of focussing to place a well-marked line drawing in the place where the plate is situated, and focus this on a screen where the transparency would be placed. He preferred slow plates for making the enlarged negatives, as more latitude was obtainable. He passed round some fine specimens of enlarged negatives and prints in carbon.

AUGUST 31, Mr. Goodwin in the chair.—As this was an informal meeting, there was no set programme arranged, and members confined themselves to answering and discussing various points as they were raised. Mr. COX asked if any one had experienced fog resulting from reflection from the water in photographing a scene with water in the foreground. The light reflected therefrom was said to sometimes appear brighter than the sky, but, on testing it by means of examining the print through a hole in a piece of cardboard, it was found to be not really so. A lengthy discussion on pinhole photography then took place, and several members, including Messrs. Child Bayley, Golding, and Goodwin, promised to bring up prints in their possession at the next meeting. The Secretary showed prints of a negative in which a mark in the sky, which showed plainly in the print and negative before the latter was intensified, had quite disappeared after intensification had taken place. The Secretary then distributed tickets for the forthcoming lectures organized by the Affiliation of Photographic Societies' Committee.

Liverpool Amateur Photographic Association.—On Saturday, the 22nd ult., a number of the members of this Association, under the leadership of Mr. William Tomkinson, visited Woodchurch, Burton, Puddington, and Shotwick. This, being an excursion by waggonette, was an excellent opportunity for seeing this picturesque part of Cheshire at its best, the only drawback being the limited time allowed at each place; but, in face of all the difficulties, a considerable number of plates were submitted to the action of light, and the results are anxiously looked forward to. Messrs. Paul Lange, H. Lupton, H. Holt, J. Sirett Brown (the President), and many others were of the party.

FORTHCOMING EXHIBITIONS.

1896.	
Sept. 24–Nov. 7	Photographic Salon, Dudley Gallery, Piccadilly. Alfred Maskell, Dudley Gallery, Piccadilly.
,, 28–Nov. 12 ...	Royal Photographic Society. R. Child Bayley, 12, Hanover-square.
Dec. 1896–Jan. 1897	Bristol International.

Patent News.

THE following applications for Patents were made between August 17 and August 22, 1896:—

PRINTING FRAMES.—No. 18,163. "An Improvement in Photographic Printing Frames." C. W. BAYLISS.

CAMERAS.—No. 18,228. "Improvements in Photographic Cameras." Complete specification. P. K. STERN.

LANTERNS.—No. 18,323. "Improvements in Projection Lanterns." W. I. CHADWICK.

CARRIERS.—No. 18,514. "An Improved Lantern-slide Holder or Carrier." J. H. FOWLER.

LANTERNS.—No. 18,579. "An Improved Optical Lantern." W. BUTCHER and W. F. BUTCHER.

PHOTOGRAPH FRAMES.—No. 18,595. "Improvements in Combination Photograph Frames and Stands for Jewellery and the like." R. MANDER.

Correspondence.

☞ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

"THE POOR CHEMIST AGAIN."

To the EDITORS.

GENTLEMEN,—With the major portion of Mr. Hampson's letter, in a recent issue, I had little sympathy; at the same time your own paragraph, which I understand you reiterate, was calculated to raise the backs of some of the devoted adherents of the Pharmaceutical Society.

In that paragraph you stated that, "not long ago a firm of oilmen were prosecuted for selling a well-known brand of fly papers, and were fined 5*l.*; this proves that only pharmaceutical chemists can sell fly papers." Now, of course, this reads like an atrocity. But the fact is you omit to state that the fly papers referred to contained *arsenic* in appreciable quantities; that as a matter of common knowledge, presuming that the varieties of fly papers number 144, *any one* can sell 143 of the number without restriction whatever! Then your "this proves, &c," is all wrong, because any person *on the register* can sell poisons regardless of the "pharmaceutical prefix."

Now Mr. Hewitt comes on the board with another grievance. To the

more intelligent photographer it is no doubt monstrously absurd that he should ask for carbonate of soda and get *bi*carbonate; but in the minds of the vast majority of customers it would be *criminal* to give washing soda when carbonate is asked for. To my mind the absurdity lies in the fact that a photographer should go to this particular chemist (who probably professes no special knowledge of photography) in preference to the two photo-chemists in the same town and within easy reach, to say nothing of the depôt of Mawson & Swan over the bridge! For the rest, I should like to hear the evidence of the pharmaceutical chemist referred to upon this question.

The business of a chemist is choke-full of anomalies, *e.g.*, people *will* ask for *carbonate* when they mean *bi*carbonate of soda or potash; for *liquorice* powder, when they mean a compound of sulphur, senna, fennel, and sugar, &c.; for hundreds of other things which if supplied *literally*, would grievously offend them.

Now friend "Cosmos" has a cut at us for occasional prescribing. Is it possible there is a man living, including "Cosmos" himself, who has not at some time or other applied to his chemist for a "draught or a bottle of stuff for a cold, cough, or touch of rheumatics?"

People are not so free of their guineas as to rush off to the doctor every time they get an ache or a pain. There is a decided preference—I can speak from practical experience in various parts of the country—amongst all ranks, from the peer downwards, to consult the chemist, at all events to commence with, and before laying out his gold; and why should he not? The work is simply thrust upon us, and we should be "thick heads" indeed, "to pass on" in all cases these anxious inquiries to the nearest medical man who will, probably, make up the medicine himself, and forget to thank you for sending him the patient! I *have* known such cases. No, gentlemen, all experience proves that "a bird in the hand is worth two in the bush." Besides, after all, what about the liberty of the subject to go where he will, and consult whom he will? which liberty I imagine "Cosmos" has very much at heart.

But I must have some consideration for your space.—I am, yours, &c.,

Nottingham. J. PIKE.

THE CITY AND GUILDS EXAMINATION.

To the EDITORS.

GENTLEMEN,—I read your Ex Cathedrâ notes of the JOURNAL to-day, and, in consequence, looked up the questions published on page 552. No. 1, Ordinary Grade, of those put at the examination, held last May, seems to me to be curious. I have been under the impression that *all* lenses had *both* visual and chemical foci, and that the "correcting" of a lens was the making these two foci coincident.

Would not the question have been better worded, and more intelligible, if it had run something like:—

"How would you ascertain whether the visual and chemical foci of a lens were, or were not, coincident?"—I am, yours, &c.,

Lower Colelate-road, Westward Ho! J. E. GUBBINS.

August 28, 1896.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:—

Lord & Binns, Dalton-street, Todmorden.—*Photograph of A. G. Eastwood, Esq.*

Rev. John Dobson Riley, The Lawn, Shepton Mallet, Somerset.—*Five photographs of Shepton Mallet, Somerset, from different points of view.*

Michael Buckley, 117, George-street, Limerick.—*Group of Dean Whits and bishops of South of Ireland. Group of Dean White and bishops and priests of South of Ireland.*

John Stuart, 120, Buchanan-street, Glasgow.—*Photograph of His Excellency Li Hung Chang and suite arriving at Messrs. Neilson's works, Glasgow. Photograph of His Excellency Li Hung Chang and suite with Lord Provost and party at Messrs. Neilson's works, Glasgow.*

ALFRED FREKE; DRINKWATER BUTT; T. A. KAY; TURNER & DRINKWATER; H. W. L.—RECEIVED. Thanks. See under Ex Cathedrâ.

T. M. TURNBULL.—RECEIVED. Thanks. We shall probably make an extract from the letters in our next.

PHOTOGRAPHY AT THE CAPE.—OPERATOR. From what we have heard from one or two who have returned during the last year or so, we should scarcely advise you to go there with the view of getting employment in photography.

ELECTRIC RETOUCHER.—WOOD & CO. write: "Can you advise us where we may obtain the "Electric Retouching Pencil" as recently advertised? We are desirous of purchasing."—In reply: Harry's Electric Retoucher is (or was) advertised by Messrs. O. Sichel & Co., 52, Bunhill-row, E.C.

SCRATCHED LENS.—S. WILMOT. From your description the scratches on the back glass will make no practical difference in the working of the lens, but they make a difference in the market value of the instrument. If the lens is scratched, as stated, we should say that the sum asked for is quite enough.

LENS.—T. MCALPINE. It is impossible to give the slightest idea as to what the lens will cover, although you have given its diameter with great minuteness. The diameter of a lens is no criterion as to its covering powers. It is its focus, and the aperture it is worked with, that are the proper guides as to that.

BROMIDES FOR PLATINOTYPES.—M. R. E. Bromide prints, we fear, are often passed off as platinotypes. But it is a fraud, and comes within the false trade description law. Because others do it, that will be no justification, in the eye of the law, for your doing it if proceedings are taken against you. The fraud is easily detected by an expert, if not by the public.

STUDIO BUILDING.—E. S. J. Your neighbour may threaten as much as he likes, but he cannot prevent you from building the studio in the way you propose; but he can, as he says he will if he cannot stop the building, put up a high hoarding against his own wall, to stop out all your side light. Each of you can put up what you like on your own premises.

DOUBTFUL COPYRIGHT.—LANTERNIST. We cannot say for certain; but we have very little doubt that there is a good copyright in the photograph in question. A search at Stationers' Hall will not help you, as the work, being of German origin, if it is copyright in Germany, it would also, under the International Copyright Act, be copyright here, and would not be registered at Stationers' Hall.

SPOTS.—B. & Co. say: "We enclose a few bits of prints, with certain spots we cannot explain, which occasionally happen to our enlargements and prints. Could you kindly explain and greatly oblige?"—The spots appear to be due to small splashes of deleterious matter such as the developer, or maybe to particles of a reducing agent (iron or hydroquinone, for example) settling on the prints while they are wet.

DARK PRINTS.—R. HARDING. Several different methods have, from time to time, been described for reducing over-printed prints; but the method followed by professionals is to tear them up and make fresh ones. It is the best, and cheapest in the end, as reduced prints are never so good as properly printed ones, and, sometimes, not so permanent. It would not pay professionals to waste time in "vamping up" faulty prints.

EXPOSURE NOTE-BOOK WANTED.—R. SIMPSON writes: "I shall feel very much obliged if you could obtain for me *The Practical Index of Photographic Exposure*, by A. R. Wormald. Please reply by return of post the cost of it, which I will at once remit. Trusting you will be able to obtain it immediately, and let me know."—Our correspondent had better address Mr. Wormald, Sutton, Surrey, or some photographic dealer. We have not yet started business in the latter capacity.

STAINS.—W. L. NASH writes: "Will you be good enough to tell me what you think is the cause of the yellow discolouration over the middle of the horse in enclosed bromide enlargement? The print was fixed for half an hour in a hypo bath, four ounces to the pint. It was washed in running water for two hours and a half, and mounted with Higgins' mountant. I made two enlargements, this one and another. They were fixed in the same bath, using two pints of the solution, but they were washed in separate dishes. The other enlargement has no stain whatever."—The stain is due to the fixing. In all probability the prints were allowed to stick together when they were first put into the hyposulphite bath instead of being kept moving.

METOL FOR BROMIDE WORK.—ENLARGEMENT says: "I have for some time been using metol for bromide work, but find that, while possessing so many great advantages over iron that I do not wish to give it up with thin or flat negatives, it does not yield as brilliant prints as the latter developer, giving only grey tones, although with good negatives blacks are readily obtainable. I enclose my formula, and should be greatly obliged if you could suggest any modification or addition which shall at once give more contrast, not unfit it for ordinary negatives, and not impair its keeping qualities."—In reply: We have succeeded very well, under circumstances similar to yours, with a three-solution metol developer containing hydroquinone. See pp. 849-50 of the ALMANAC for 1896 for the formula.

PRINTING ON SILK.—T. G. SNOWDON says: "I am wishing to try a little printing on silk. I have used a formula I saw in the ALMANAC of a few years since. I cannot now remember it, and have not got the book at hand. It is the gelatine sizing bath previous to sensitising I remember least of. Would you mind repeating process, or at least give sizing bath, in the Answers to Correspondents in JOURNAL of Friday next. I have just used Iceland moss and chloride of ammonia, but it does not seem like the results I had before."—In reply: We cannot trace the formula you refer to. Possibly the following, due to Mallman & Scolik, will answer your purpose: 1. Tannin, 40 grammes; water, 100 c. c. 2. Common salt, 40 grammes; arrowroot, 40 grammes; acetic acid, 150 c. c.; water 1000 c. c. Gradually mix No. 1 with No. 2, shake and filter. Immerse the silk, dry and sensitise on a bath of 1 part of silver to 10 ounces of water, to which a drop or two of nitric acid has been added. If the method does not give the results you want, write us again.

*** Several Answers to Correspondents unavoidably left over.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1897 Vol. XLIII.—SEPTEMBER 11, 1896.

Contents.

OUR FORTHCOMING ALMANAC.

The time of year has arrived when it is necessary for us to take in hand the preparation of The British Journal Photographic Almanac for 1897. A feature of the volume for the past thirty years has been the co-operation of numerous friends and readers of the Journal, and the Editor takes the opportunity to express the hope that the support so kindly placed at the disposal of his predecessors may be continued to him.

We especially invite contributions on topics of practical interest, and should feel obliged if the articles and any accompanying sketches are sent to us at the earliest possible date.

Secretaries of Societies, and especially of those established since the appearance of the last Almanac, will oblige us by forwarding lists of officers and other details for inclusion in the Directory of Photographic Societies, in order that the list may be made as complete as possible.

The Publishers wish us to remind intending advertisers that the announcement pages of the Almanac are already filling rapidly, and that, to ensure insertion and good positions, orders and copy should reach them without delay.

EX CATHEDRÂ.

We continue to receive correspondence from photographers who have been approached by the firm of diarists previously referred to, to allow their names to be placed in an almanac as willing to take photographs for nothing. Messrs. Turner & Drinkwater, of Hull, write us that "it is sincerely to be hoped that every photographer throughout the country will resent the offer in the way it fully deserves. The times may not be the happiest the profession has known, and the desire to obtain new business may be in some districts painfully keen, but it seems scarcely credible that any self-respecting man can be foolish enough to believe either his own individual interests or those of the community at large can be advanced by the methods proposed to him."

* * *

The answer sent by Messrs. Turner & Drinkwater in reply to the circular was as follows: "We are in receipt of your circular letter, offering to place our names on a list of photographers to whom your coupon-holders may be sent. Will you kindly inform us what is the intended remuneration from your firm to photographers who may honour the coupons in the way described?" This elicited the following response: "You do not seem to have grasped the idea contained in our letter *re* photographing. We do not propose to give any remuneration ourselves at all; but, inasmuch as probably eleven persons out of a dozen would not be satisfied with a single copy, but would order a quantity at full prices, the scheme should prove a most excellent one from the photographer's point of view; that, at all events, is the most general opinion of the photographic profession. If, however, it does not meet with your approval, we will make other arrangements for your district."

* * *

From what has already appeared in these columns on the subject it is highly probable that there are a considerable number of districts in which other arrangements may have to be made. As to its being the general opinion of the photographic profession that the scheme *should* prove a most excellent one, the authors of this circular are probably not wide of the mark; but, that the scheme is at all likely to *be* in any way profitable to the photographer, we take it that no disinterested person can for a moment think.

* * *

The Admiralty recently invited tenders for photographs of buildings, &c., in the Portsmouth district, and by the courtesy

of a friend we have been enabled to peruse the specification issued for the guidance of those photographers who might desire to submit tenders for the work. Some of the conditions imposed are rather stringent, and, unless we are much mistaken, are of a nature to deter many photographers from coveting the Government's patronage. The specification lays it down that the negatives are to be taken on gelatine emulsion plates, 12×10, freshly made and of best quality only, and possessing brilliancy of image with a good range of half-tone and free from pinholes and all other defects. Any negatives giving a thin flat image would be rejected. No fault could be found with this condition, we opine.

* * *

To a further condition that each negative must show perfect definition all over the plate, a falling off at the edges ensuring rejection, no objection could be taken, although we frequently find that even amongst expert photographers there is much diversity of opinion on the subject of what constitutes perfect photographic definition. The negatives, says the Admiralty specification, must be thoroughly fixed in at least two baths of freshly made hypo of the usual strength, and be then subjected to a continuous washing in running water for at least twelve hours. The second hypo bath certainly makes the assurance of complete fixation doubly sure, but it is not essential, and twelve hours is an excessively long washing to give gelatine negatives.

* * *

Platinum prints are specified for and they are to stand the mercuric chloride test. The Government are evidently up to the tricks of some unscrupulous photographers in supplying bromide prints for platinotypes. Prints of a hard or chalky appearance would be rejected, and when trimmed they are to measure $11\frac{3}{8} \times 9\frac{3}{8}$. A minimum number of six prints would be ordered, and the contractor must fix his apparatus in such a position as to embrace the angles of view as desired by the officer in charge of the works. On the whole, it appears to us that an exact compliance with the conditions laid down in the specifications would by no means remove the risk of a photographer having his negatives and prints rejected at the caprice of a Government official, who appears to suffer from an excess of knowledge. The order seems to be one for which not many photographers would be anxious to tender.

* * *

The Photographic Society of India's Ninth Annual International Exhibition of Photographs and Photographic Apparatus will be held in Calcutta during January and February, 1897. The Exhibition will be open to the world. Exhibits from Europe should be dispatched by the first week in November, or not later than November 15, and those from America a fortnight earlier. English exhibits may, if preferred, be sent through Mr. R. Child Bayley, 12, Hanover-square, London, and should reach him not later than November 1. Mr. Child Bayley will supply further particulars and entry forms.

FIXING AND WASHING PRINTS.

The subject of fixing and washing prints continues to exercise the minds of many of our readers, and probably there is no question in the whole range of photographic chemistry that better deserves the amount of attention that is given to it. In the matter of negatives even when treated with comparative carelessness, we never have the slightest doubt on the score of permanence; whereas with prints, whether on albumen or other surfaced paper, it still seems to be a moot question if absolute permanence can be claimed under any circumstances.

The recent researches of Messrs. Haddon and Grundy have thrown a good deal of light on points that have been hitherto somewhat obscure, and, while they indicate that the prolonged washings that were formerly resorted to after fixing are entirely unnecessary, if not absolutely injurious, they still suggest the suspicion that under no conditions can a silver print be considered free from the germs of ultimate decay. On the other hand, Mr. Edward Dunmore, who has had a lengthy and intimate practical acquaintance with silver printing on a large scale, points out in an article last week a fact that is very well known to many of our readers, that there are prints in existence that have shown no signs of deterioration during many, probably thirty or forty, years; and, as he suggests, there must be some rule, if we only knew it, by which such results could be attained with certainty. In pointing out, however, a number of the causes that operate to bring about want of permanence in practice, although he lays some stress upon the possible want of care when working on a large scale as being a prolific cause of fading and instability, he at the same time appears to recognise some purely chemical reasons why prints should fade in spite of the exercise of all care, or, at least, some causes which should operate to render their permanency doubtful.

We hold the opinion very strongly, as we endeavoured to show in an article a few weeks back, that with proper care and materials of ordinarily good quality, permanency, at least to the extent that we can fairly expect it in silver prints, should be an assured quality, and that any falling away from the regular standard of stability can be traced, or at least charged, to causes which, to put it plainly, are avoidable if only sufficient individual care were given to each print. In other words, that, while the process and the system may approach sufficiently near perfection for the purpose of ordinary permanency, the method of working on a practical scale falls short of what is necessary to secure the best results.

To recapitulate what we said but a short time back, and, indeed, to repeat what Mr. Dunmore says last week, theoretically, chloride of silver is perfectly soluble in hyposulphite of soda, and, if prints are properly fixed, there need be no difficulty in removing the products of the fixing operation. In fact, given perfect or sufficient fixation, there only remains the necessity for sufficient washing to remove the whole of the silver salt; and it is here, we think, where the method of working fails. It is true that in Messrs. Haddon and Grundy's experiments they have found that it is impossible to remove the very last traces of silver from prints, however long they may be washed. But then the question may be raised whether this is the result of imperfect fixation or imperfect washing; whether it is due to the formation of some silver compound in the prints that the fixing solution is incapable of removing, or to decomposition during the process of washing of some of the originally soluble products of the fixing process.

To illustrate what we mean, we may cite an experiment that will very clearly show how a slight variation in the method of working will altogether alter the character of the result. Let an ordinary gelatine plate be fixed in a bath of clean, fresh hypo; and, in order to eliminate any chance of stains from outside causes, let the plate be an unexposed and undeveloped one. In fact, let the solution that clings to the plate, when

removed from the fixing bath, be one of pure bromide of silver in clean and uncoloured hypo. Without washing the plate, allow some of the solution clinging to it drop on to clean white blotting-paper, or, better still, linen, upon which it will leave no immediate stain. Let one portion of the blotting-paper or linen be at once subjected to thorough washing in ordinary water, after the manner of a print, and let the other be put on one side for twenty-four hours, and then washed with equal care and both dried. At this stage, probably neither will show any signs of discolouration; but, if they be put away in the dark, in course of time a very distinct yellow stain will be developed on that portion that was not immediately washed.

The experiment may be extended by allowing a third portion of paper or linen to remain unwashed for, say, twenty-four hours, and then, either with or without previous washing, immerse it in clean hypo for a short time, and finally wash well. In this case also, despite the interval allowed to elapse before washing, no stain will appear in course of time, showing that, until the decomposition has taken a visible form, it is preventible, if not by simple washing, at least by a repetition of the fixing process.

A somewhat analogous result is obtained, as any worker with gelatine plates is aware, by neglecting to wash a negative on its removal from the fixing bath. If two negatives be placed side by side in the same dish until fixed, and one be then removed and placed to drain without washing, it will be found, in the course of half an hour, or perhaps less, to have acquired a strong yellow colouration, while the other plate, although allowed to remain all the time, and even for a very much longer period, in the solution, will retain its original colourless character. The inference from which is clearly that, although the fixing of a print or of a negative may be efficiently performed, and the perfectly soluble double salt produced, the latter is very liable to rapid decomposition, *except in the presence of an excess of the fixing agent.*

Perhaps this forms the true explanation of many examples of fading or discolouration that are supposed to arise from quite different causes. For instance, it has been stated that exposure to light before the negative or print has been sufficiently washed will cause discolouration; but, from experiments frequently repeated with solutions of pure chloride or bromide of silver in hypo, exposure to light has never produced any effect, though exposure to the atmosphere may. In fact, it may be noticed that almost instantly a print is immersed in the fixing bath it loses its sensitiveness to ordinary daylight.

Then, again, it is supposed by many that one of the causes of the gradual fading of silver prints, at least upon albumen paper, is the formation of a silver compound that the fixing solution is incapable of dissolving; but this does not seem to be a reasonable explanation if we make the experiment of precipitating albumenate of silver, and, after thoroughly washing it, treating it with hypo. It will be found to be perfectly and completely soluble, and, so far as we remember from experiments made in this direction, the solution so formed is not liable to reprecipitate the silver salt on dilution.

We conclude by repeating our impression that, with fair and proper treatment, there is no reason why silver prints should not be practically permanent; where this is not the case, it is the fault of the method rather than of the chemical process.

Millais' Work.—The panels in the Judges' lodgings at Leeds, it appears, were painted by the late President of the Royal Academy when he was only a lad of eighteen. The work is not signed by the artist, but there seems to be no question as to its authenticity. The panels, we hear, are now to be removed to the Corporation Art Gallery. The Corporation, doubtless, think the late artist's work will be better located in its Art Gallery than in the Judges' lodgings. The Leeds Art Gallery contains some fine works, as most of the late Conventioners know.

Li Hung Chang in America.—Li seems to have been more liberal in America than he is credited with having been while here. It is said that before leaving New York he had a bouquet presented to every lady staying at the hotel. The Manager had a present of some tea and a photograph. All the clerks in the hotel also were presented with Li's photograph, while the waiters received more substantial presents. Evidently the Celestial was on good terms with himself, as seen in his photographs, for he seems to have been particularly liberal in their distribution wherever he went.

An Extremely Delicate Test for Iodine.—A small quantity of acetaldehyde (say, twenty drops) is left for an hour in an otherwise empty flask of large size—about a quart—and is then made into an emulsion, with ten times as much water. The solution suspected of containing an iodide is then treated by the addition of a very small quantity of the new reagent, which has the property of liberating iodine (but not bromine or chlorine) from solutions of their salts. An extremely small quantity of colourless bisulphide of carbon is next shaken up with the liquid under examination, when, if no more than one part in fifty thousand be present, it can be perceived by the pink colour it will impart to the bisulphide.

Novel Use of the X Rays.—The latest use to which the Röntgen rays have been put, or the latest we are aware of, is for advertising purposes. In an enterprising bootmaker's window, not a hundred miles from Ludgate-circus, are shown a couple of sciographs. One is of a foot showing a distortion of the bones, caused by wearing an ill-fitting shoe; the other is of the sole of a boot, showing the bent pins and brads, &c., it contained. Of course there was an intimation that the boots were not made at that establishment. The advertisement seemed to fulfil its object, as the sciographs appeared to attract the attention of passers-by. What is the next use that will be made of Röntgen's discovery? one may naturally ask.

Chemical Inactivity of the Röntgen Rays.—In view of the familiar effect of light rays on a photographic plate, which can only be brought about by some initial decomposition or chemical action on the silver in the film, it is surprising to learn from a paper by Messrs. H. B. Dixon and H. Brereton Baker, read at the last meeting of the Chemical Society, that a negative result was obtained in every case they investigated, in endeavouring to discover if the rays were able to influence chemical change, either by starting it or by accelerating or diminishing it, after it has been started by ordinary light. They tried carbon monoxide and hydrogen (dried and moist), hydrogen and oxygen, hydrogen and chlorine, carbon monoxide and chlorine, hydrogen sulphide and sulphur dioxide, solutions of sodium sulphite and oxygen, slow oxidation of phosphorus, decomposition of hydrogen peroxide. The result was the same in each case.

Röntgen Rays with a Wimshurst Machine.—Though much was said in the early stages of the X-ray fever about the usefulness of this machine, most observers appear to have settled down to batteries or dynamos as a source of electricity; but a writer in the *English Mechanic* describes the work done by Mr. H. C. Ogden, of Middletown, New York, with a home-made machine of the Wimshurst pattern which will set experimenters thinking. We refer readers to the communication itself* for full details; it will suffice for us to state that Mr. Ogden is represented as having (the machine

* *English Mechanic*, vol. lxiv. p. 61.

being home-made and only twenty inches in diameter) obtained an impression by the Röntgen rays (using a Crookes' tube of course) in the one-thousandth part of a second. Indeed, he obtained a representation of one object by eight sparks which he estimates as being of the total duration of the one-three-thousandth of a second.

The British Museum.—It is well known that the subject of the separation of the national collection of books from the British Museum has been discussed for several years past, though it has as yet come to nothing. Something, it seems, will have to be done in the near future, for both departments are rapidly outgrowing their resources. The Museum is acquiring so many fresh treasures that they cannot be efficiently displayed, while the library, on the other hand, is already so overcrowded, that thousands of books are at present practically inaccessible to the public. Most of our readers who have occasion to consult the library on works photographic are fully aware of the time it often takes to obtain what is required. Not only is this the case with the works in question, but with books in general, if they happen to be somewhat old. With more space at command, this would, no doubt, be obviated, to the great convenience of those who have, at times, to refer to the books.

A New Art Work by Mr. W. J. Stillman.—It is announced that Mr. W. J. Stillman is now engaged on editing a large work entitled *Venus and Apollo, in Painting and Sculpture*, which will contain over eighty large-sized photogravures of works by celebrated old masters and sculptors. The work will be published late in the autumn. The price of the work we do not know, but, as it contains so many photogravures of large size, it necessarily will be somewhat costly. Many of our older readers will be pleased to hear that Mr. Stillman "is in the land of the living," though his name seldom now appears in connexion with photography. This is due rather to his long residence abroad than anything else, for he is still an enthusiast in photography. A quarter of a century ago he invented a portable camera, "Stillman's camera," which was at that time an improvement in many features on what had gone before. Mr. Stillman's photographic work was always identified with its artistic as well as its technical excellence, even in the wet-plate days.

The Royal Arms—a Caution.—Reference has more than once been made in these columns to the use of the Royal Arms by photographers who are not privileged to do so. In the "legal notices" in some of the daily papers, last week, is an advertisement of the solicitors for the Incorporated Association of her Majesty's Warrant-holders, Limited, dated August 31. It gives notice that proceedings will be taken against all persons who display the Royal Arms, or a near copy thereof, on the exterior of their premises, their bill heads, stationery, or otherwise, except they hold a warrant to do so, unless they forthwith discontinue such illegal use. The advertisement quotes from the Statute 46 and 47, cap. 57, sec. 106, "Any person who without the authority of her Majesty, or any of the Royal family, or of any Government department, assumes or uses in connexion with any trade, business, calling, or profession, the Royal Arms, or arms so nearly resembling the same as to be calculated to deceive, shall be liable on summary conviction to a fine not exceeding 20*l*." We call special attention to this advertisement, because we know that some use the Royal Arms thinking that they are entitled to do so through having supplied photographs to the Queen or some members of the Royal family. This is not the case; the warrant to do so must be obtained.

Enamelled Iron Trays.—Of late years a most marked improvement has taken place in the manufacture of iron, or, it may be, steel, trays covered with enamel. Time was when such vessels were utterly useless for photographic and many other purposes, as the coating used to break and chip or shell off without any apparent cause. The later productions of the kind, however, are so differently made that they have become most valuable adjuncts to the dark room or printing room. For platinum hot-bath printing it would be difficult to find an efficient substitute, as they can be heated over a naked gas flame, and the liquid raised to boiling point without danger. The enamel keeps its colour, and is apparently unacted upon by chemicals. It would, however, appear that there is danger of the introduction of a new type of enamel which is readily acted upon by chemicals, and which, under some conditions, might be detrimental to photographic processes in which it was utilised. It will, of course, be understood that we are referring to actual enamel, that is, a substance of the nature of glass fused to the surface of the metal, and not the so-called enamel composed only of a coating of some species of varnish, well stoved to give hardness. The usual enamels contain generally silica, boric acid, alumina, and alkalies, and for white enamel, such as is used in photographic dishes, stannic oxide. The most recent kind to which we draw attention is composed of sodium and potassium, combined with silica, lead, arsenic, and a trace of cobalt, the stannic oxide of the older kind being replaced by arsenate. It is found that this enamel is attacked by dilute acids, and should thus be excluded from photographic use, not to speak of the dangerous character it would possess for any culinary purpose, which scarcely concerns us, though the domestic "pie-dish" and the like play an important part in many an amateur's outfit.

Other Dishes to be Rejected.—It is often suggested that dishes of aluminium should be used to replace ebonite and *papier-mâché;* but a recently published paper by Herr Christian Göttig gives an excellent idea of the value or otherwise of this metal for this purpose. He finds among other things that, providing it is sufficiently dilute, ammonia dissolves aluminium with comparative readiness, hydrogen gas being given off even when there is only ·025 of ammonia present; that is to say, about a grain of ammonia in eight ounces of water, a quantity far less than would be found in a very weak developing solution. It is thus evident that the life of such a dish could not be expected to be long, and there would be the added factor to be considered in pyro-ammonia development, of the hydrogen gas evolved. True, this might be looked upon as a further addition to the reducing power of the solution, but its use would be, at present at any rate, purely empirical. Further, so long as ammonia is present, its action on the tray would still continue though it were in the form of a salt; in fact, an acid solution of ammonia has a still stronger action on the metal, though in this instance no gas is evolved.

FOREIGN NEWS AND NOTES.

The Spectrum of Argon.—Eder and Valenta have just presented to the Imperial Academy of Sciences in Vienna an important monograph upon the spectrum of argon, which is illustrated by some very fine photogravures. They have photographed and measured the wave-length—about two thousand lines in the argon spectrum—with an error not exceeding one-hundredth to one-thousandth of a ten-millionth of a millimetre. Although it was known that argon had a red and a blue spectrum, these two scientists have discovered a third or white spectrum, and also that some of the lines show a displacement towards the red end of the spectrum which will probably cause a change, or at least a more stringent examination into Doppler's law, which is so much used in astr-ophysical researches, and from which the motion of some of the stars has been calculated, for they have proved that change of wave-length may occur, although the source of light is stationary. The authors finally come to the conclusion that argon is a mixture of at least two elements.

Damp *versus* Dry Gelatine Plates.—Helheim points out, in the *Photographisches Archiv*, that, if part of a plate is wetted, and then the whole exposed in the camera, the wet portion will, on development, show but the merest trace of an image, whilst the dry part will be well developed. This has very frequently been ascribed to an actual lowering of the sensitiveness, but Helheim states that this is hardly the case, as, if a plate, half of which has been damped, is exposed and then allowed to dry, there is no difference to be seen,

and that probably the so-called loss of sensitiveness is due to the fact that, when the film is wet, it merely has a different resistant action to the various constituents of the developer.

Sensitiveness and Temperature.—According to the researches of Dr. Precht and Schellen, the light-sensitiveness of gelatino-bromide of silver is not affected by variation in temperature between −20° and +90° C., as on development they gave the same density of precipitated silver. Meyer and Acworth have shown that the photo-chemical decomposition of silver chloride is diminished by heat; and Abney's experiments before the Camera Club, which were preceded by Joly's, proved that there was a lowering of sensitiveness with the drop in temperature.

Some New Photographs of the Pleiades.—The well-known astronomer Stratonow has been successful in obtaining some very successful negatives of the Pleiades. One was obtained with an exposure of nearly ten hours on three successive nights; another received twenty-five hours' exposure on nine nights, and a third seventeen and a half hours' on nine nights. A twelve-inch refractor was used, and on the second negative no less than 6614 stars have been counted on four square degrees. Several nebulæ of distinctly new form have been also photographed on the plates.

Reticulation of Carbon Tissue.—Rapp points out that the reticulation of carbon tissue which is so often met with in summer is generally due to too rapid drying of the tissue and unequal contraction or expansion between the gelatine and its support, and that this is more noticeable when a stiff support, such as glass, is used. The remedy for this is to use a substratum of chrome alum gelatine, made by adding a six per cent. solution of chrome alum to a five per cent. solution of gelatine till it becomes quite thick and coagulated, and then adding glacial acetic acid to make it fluid. It may also be avoided by coating the tissue before transferring with thin enamel collodion; but this is more suitable for a flexible temporary or final support.

The Colour of Chloride Transparencies.—Goderus & Dupont have published in the *Bulletin Belge* some experiments upon the variation of tones to be obtained on chloride plates, and they have come to the conclusion that the colour is in no way dependent upon the duration of exposure, but rather on the amount of bromide in the developer and the duration of development. Goderus recommends a ferrous-oxalate developer composed of thirty per cent. solution of sodium oxalate 60 parts, thirty per cent. solution of ferrous sulphate 5 parts, and ten per cent. solution of potassium bromide 200 parts. The image is first yellow, but, as development proceeds, runs the whole gamut of colours to a violet-black. Dupont, on the other hand, uses a six per cent. solution of sodium sulphite to which 0·5 per cent. of amidol is added, and the plates are bathed in a ten per cent. solution of ammonium bromide, and upon the length of their stay in this bath depends the colour. If they are bathed for ten seconds, a sort of green moonlight tone is obtained; with twenty-five seconds, a grass-green; with thirty to forty seconds, a greenish-yellow, whilst with sixty seconds a good transparent black is obtained. The plate should be laid in the amidol solution without washing off the bromide.

To Reduce Harsh Contrasts.—The old method of improving negatives with hard contrasts by coating them with bichromated gelatine, and exposing till the shadows have acted thoroughly and before the high lights have had time to act, has been again revived by a writer in the *Deutsche Photographen Zeitung*, who further suggests the tinting of the insoluble chromated gelatine after thoroughly washing the various dyes. This method is extremely useful in certain cases, but presents no features of novelty, and is somewhat inferior in results to bleaching the images, redeveloping and refixing before the high lights are developed through.

Yellowed Platinotypes.—In the current number of the *Photographische Mittheilungen* Poulenc Frères suggest the use of a five per cent. solution of sodium hypochlorite for bleaching yellowed platinotypes, the prints being immersed in successive baths of this till they become quite white, and after careful washing the prints should be rinsed in the ordinary hypochloric acid bath to destroy the last traces of hypochlorite.

Coloured Photographs.—The *Actiengesellschaft für Anilinfabrication*, in Berlin, have patented a process for the production of coloured prints, in which use is made of the diazo compounds of certain aniline dyes, which is somewhat similar to the diazotype process of Messrs. Green, Cross, & Bevan, and Feertype invented by Dr. Feer. The diazo compounds are spread on paper, dried, exposed, and then developed, the various colours being obtained by the use of different solutions.

PHOTOGRAPHIC WORKERS AT WORK.

XI.—The Brighton Photographic Company at Brighton.

A flying visit to the "Queen of Watering-places" enables us to reach the premises of the Brighton Photographic Company just at the time when the *employés* have left work for the day, and thus we have an excellent opportunity of passing freely through the different rooms, and noting the various installations the Company possess in order to fit them to conduct the many branches of their business. It might at the first offset occur to the reader that an enlarging company, established on the southern coast, would only enjoy a greater or less degree of local patronage, and he would, doubtless, be just as much surprised as we were to learn, from visible evidence, that the Brighton Photographic Company execute work for photographers from all over the kingdom, and that, in its nature and extent, the firm well ranks with the large printing and enlarging works that are to be found in the suburbs of London.

The works, situated in Clarence-square, are contained in a three-storied building, isolated on all sides and commanding a good light—no mean advantage when it is considered that much of the Company's enlarging work is done by daylight. The offices and printing rooms are in another building close by; and the packing and mounting rooms in the main building. A brief gossip with Mr. Wicks, sen., whose photographic reminiscences extend back to the Daguerreotype era, prefaces our delivery into the hands of Mr. Wicks, jun., in whose company we ascend to the first floor and find ourselves in the room devoted to the production of enlarged negatives, &c., by the wet-plate process. Here the system employed is of the simplest. The sensitising solution for the collodionised plate is contained in a large bath swung on trunnions, and the bath being partly revolved a steady and even flow of solution is given to the plate which, when the bath is again inclined to the normal angle, rests on a ledge just free of the solution. One of these baths is for plates, 48×36, and requires ten gallons of silver solution. Reflected daylight during all but the winter months is utilised for projecting the image on to the wet plate, focussing being done on ground glass by moving the frame, which runs in a tramway—a system adopted in several rooms throughout the works. The exposures vary between four and fifteen minutes. We may note, in passing, that for reproduction purposes dry plates, after many trials, do not yet seem likely to oust wet collodion at the Brighton works.

Our attention is next directed to a large reducing camera, which occupies a small room adjacent to the one we have just referred to. This piece of apparatus we should think well pays for itself. It is about ten feet long, and is mounted on a light wooden frame running on four feet to which castors are attached, and it is thus easily moved from one part of the room to another. A simple screw adjustment actuating the lens board allows of the objective being centered, or moved in any part of the frame horizontally or vertically, while a movable back allows of two or three successive and accurately registered exposures being made on one plate or of two lantern slides also being so made. A simple clamp adjustment to the frame, moreover, admits of the correction of an erratic water or sky line in the original negative, and these and other minor conveniences in the camera make us envious of a very handy piece of apparatus. Reductions can be made by this camera direct from 15×12 to lantern size.

In the rooms devoted to bromide work we note one or two useful practical ideas which tend to great comfort in working. For example, the developing lamps, glazed with non-actinic glass, are swung *over* the developing sinks, thus taking the light from the eyes of the operators

and concentrating it on to the prints or enlargements—a pleasant and common-sense arrangement. Ferrous oxalate is still used for development. (It is surprising to note what little headway the other developers have made, for bromide work, with professional photographers and enlargers.) We learn that very prolonged soaking or washing is not in favour for the fixed prints. The system adopted is to have two large slate tanks, with constantly changing water. The prints, being placed to soak in one, are taken separately, subjected to a thorough squeegeeing, and again soaked in fresh water. Half a dozen squeegeeings and soakings complete this part of the process, a final washing of two hours being then given, and Mr. Wicks assured us that the system had not yet come under suspicion as to lack of permanency of results.

The contact prints on bromide paper are made by a simple yet very ingenious plan, which saves much time and is highly effective. Electric light being available, an incandescent lamp is placed inside a square wooden box-like structure having a sheet of glass let in its top. On this the negative is placed. A large cardboard mask, with several pencilled lines as guides is next placed *in situ*, and the exposure is made by pressing the bromide paper into contact with the negative by means of a flat presser held in the left hand, the large sheet of bromide paper being moved at each exposure which is made by actuating a switch that controls the light. The latter is, of course, instantly turned on or off. With dense negatives an exposure of ten seconds is necessary, three seconds sufficing for thinner *clichés*.

Albumen paper is still used at the Brighton works, where it is sensitised on the premises; platinum and gelatino-chloride are also availed of to a considerable extent. A very large number of carbon enlargements are produced—the tissue being floated at the works—and the beautiful quality of the results that we were shown testifies both to the careful manner in which the process is worked throughout, as well as to its popularity with photographers and the public. The carbon method is also utilised for the production of cloud negatives, very many of which, on celluloid, are sent out from Brighton. Except in dark months of the year, when electricity is available, daylight is used for the enlargements that are made. A branch of the establishment which we had to miss, and which is situated in another part of the town, is devoted to colouring and finishing.

What struck us at the Brighton Photographic Company's establishment was the thoroughly workmanlike nature of the apparatus used in the various processes, and the cleanliness and orderliness everywhere visible. This being so, there exists little room for surprise that, in the many negatives, prints, enlargements, and transparencies we were shown, a very great degree of technical skill was manifested, and that the finished results sent out touch a high level of beauty and merit. Our short account hardly does justice to the admirable way in which the business is conducted.

THE POSITION OF PHARMACY.

THE recent references in our columns to the Pharmaceutical Society and its methods of administering the provisions of the Poisons Act doubtless confer great interest to many of our readers, on the two following letters that lately appeared in a Glasgow contemporary.

"To the Editor of the *Glasgow Herald*.

"Sir,—In recent years numerous prosecutions under the Pharmacy Act have called public attention in a special manner to the drug business. It is to be regretted, however, that those precautions have only diverted attention from the real difficulties with which pharmacy has to contend. Whilst the people are judging harshly of the Pharmaceutical Society in prosecuting various individuals who have transgressed against the Pharmacy Act, they are quite unaware of the far more serious difficulties with which pharmacy has to contend, and against which the Pharmacy Act appears to hurl itself in vain.

"Regarding the exact nature and scope of the Pharmacy Act much ignorance exists, not only amongst the people generally, but amongst those who are charged with the administration of it, and, in Scotland more particularly, adverse remarks made from the Bench have influenced public opinion beyond calculation. Indeed, remarks have been made at times which were calculated to diffuse the opinion that chemists are sordid, selfish, and grasping in business matters, and that they wish to wring a system of protection out of the Pharmacy Act which it was never meant to extend.

"To speak of the Pharmaceutical Society as a sort of chartered company which desires to create a monopoly in drugs is unjust in the highest degree. It has, no doubt, been reserved for the Society to take the initiative in instituting proceedings against those guilty of infringement of the Pharmacy Act; but the Act itself was framed, not in the interests of chemists, but in the interests of the general public. The same Act which provides for the public safety, by demanding that poisons shall only be sold by those acquainted with the nature and character of poisonous drugs, demands, upon the other hand, that the possession of this acquaintance shall be demonstrated upon the part of the seller by proof produced of having passed examinations of an educational nature, the scope of which is approved of by the Privy Council. It would be a gross injustice to demand special qualifications in the interests of the public from any body of men, and, at the same time, refuse protection as a counterbalance, and of such injustice the framers of the Pharmacy Act never meant to be guilty. No Act could be plainer in its language than the Pharmacy Act is, and the injustice under which chemists suffer at the present time is in no way chargeable upon the Act itself, but upon those who have persistently misadministered it. In the first clause of the Pharmacy Act the following words occur:—

"'It shall be unlawful for any person to sell or keep open shop for retailing, dispensing, or compounding poisons, or to assume or use the title "chemist and druggist," or "chemist," or "druggist," or "pharmacist," or "dispensing chemist," or "druggist," in any part of Great Britain, unless such person shall be a pharmaceutical chemist, or a chemist and druggist within the meaning of this Act,' &c.

"The meaning of this clause is perfectly plain. Every letter of it spells protection, and the whole Act from beginning to end recognises that special qualification cannot be enforced without protection. It has been decided, however, that as 'person' does not mean 'persons,' a limited company may trade in drugs, even if there are no qualified shareholders in it at all. The full significance of this finding has never become apparent to the general public, and we would hope, in the interests of justice, that it did not become apparent to those charged with the administration of the Act at the time. Private individuals who knew nothing about drugs formed companies, the entire shares in which were held within one family circle. Drug stores were in this way started all over the country by individuals in defiance of the Pharmacy Act, and greatly to the derogation of pharmacy, both from a scientific and professional point of view. Of course, it would have been better if the Act had said 'person or persons,' but there can be no mistake about the real meaning of the language in which it is actually couched. Chemists have in this matter so far had few enough friends upon their side, but I am glad to see that the London *Times* has recently come down with a strong article upon the subject. He quotes the case of a young man who served his time to the drug business and went in for the preliminary examination of the Pharmaceutical Society fifteen times without being able to pass. During that time he had frequently been prosecuted for keeping open shop, being unqualified, but at last he formed himself into a company and so escaped from all his difficulties. Of course, this was a bad case, but it was not, in my opinion, so glaringly absurd as the cases of numerous others who have formed themselves into companies, knowing nothing about the drug business at all.

"Not the least injustice of all this consists in the fact that the chemist who has been carefully trained to regard pharmacy as a responsible science, and who is therefore, by reason of this very training, possessed more of professional instinct than business instincts, is brought into competition with the roaring salesman, for whom he is no fit match. Indeed, the professional instincts are cultivated directly at the expense of the business instincts, so that the chemist cannot fairly compete with the man who looks upon drugs as mere articles of commerce, to be pushed, and roared, and placarded about the town. Things which the mere salesman can do without compunction are looked down upon by the professional man, with his keener instincts for what is in accord with the position he holds and the responsibilities he is under to support the dignity of his profession.

"An even worse feature, however, consists in this, that pharmacy is by this whole system pulled down and kept down, so that Great Britain is falling behind in the world of scientific pharmacy. In place of pharmacy being made a useful institution based upon true scientific principles, and making true scientific progress, it is degraded practically to a huge market, in which quack medicines and proprietary articles of all kinds are roared, and pushed, and crammed upon the public, regardless altogether of what diseases they can cure, if any, regardless also of the sufferings of humanity, so long as sales are made.

"In Germany and France the chemist is left to pursue his calling peacefully, and as a result almost all scientific advances in pharmacy have been made in these countries. In Great Britain the chemist has either to come to his shop door, so to speak, and roar more loudly than his unqualified opponent, or else see his family go into the workhouse. Not long ago a chemist in France took into partnership a man who was unqualified because he had cash, but the law came down and dissolved the partnership, at the same time imposing a heavy fine upon the unqualified man. If he had been in Great Britain, he might have opened twenty shops without any qualified partner at all, and our Judges would have said he was a public benefactor.

"Another heavy evil consists in this, that not only are the masters unqualified, but they employ numerous unqualified assistants, many of whom have not even learned the drug business. One qualified man is engaged at perhaps a salary of 90*l*., and ten others are unqualified. The business does 50*l*. a day, and this man has to cover his master and ten

unqualified assistants for 90*l.* a year. Truly a certificate from the Pharmaceutical Society has to go a long way. By this means ten men who have qualified at great expense and trouble are thrown upon the streets, or compelled to take what salary they can get for second-rate situations, such as managing doctors' shops, &c., for it must always be borne in mind that the drug business is a limited business, and cannot give employment to many people.

"Indeed, this fact plays a very important part in the whole matter. The drug business is so limited that it cannot be divided between qualified and unqualified men. The demand for groceries, for instance, is practically unlimited, but not so with drugs. The legitimate drug business is very much more limited than people think, and large cutting places as a rule only exist by putting up all sorts of proprietary medicines of the quack order and selling them to an all-too-credulous public. The actual consumpt of pure drugs and chemists' sundries is at the very outside calculation not over 10*s.* per head of the population per annum. I dare say, the consumpt of groceries will be about 10*l.*, but upon that subject I am not so well qualified to speak.

"Now, in these days of democracy, we have all got it into our heads that Britain is a free country and will not tolerate any form of Protection, and somehow or other this question has got swamped in the bogs of political controversy. Chemists have, in my opinion, accepted this position too readily. They have practically acknowledged that it is a matter of Free Trade *versus* Protection. I say it is nothing of the kind: the whole question is outside that of Free Trade altogether. It is entirely a matter of special protection demanded from a Government which has demanded special qualification. I am surprised that chemists don't insist more upon this point. I am surprised even that men of education who are not chemists fail to see the justice of it. I was speaking recently to a clergyman upon the subject, and I met with the usual remark—"Yes, but they keep a qualified man, don't they?" How would this clergyman, or any other clergyman, like it if some farmer or other were to step in and claim his living, at the same time giving him 90*l.* a year for doing the work? If the clergyman were to complain, I would say, "Yes, but the farmer keeps a qualified man, does he not?" And yet Government demands no special qualification from the clergyman, and doesn't care what he preaches or how he does his work. If there is a case of suicide from poison, or a case of accidental poisoning, it is odds but that the chemist at whose shop the poison was bought has his business permanently ruined, even if he was in no way to blame, by Government inquiry and officialdom, but after the man is dead, whether the clergyman did his work well or not—well, there is no Government inquiry.

"I think that the quickest way to cure all this would be for chemists to approach the Privy Council with a view to obtaining the same power to purge the register that doctors and lawyers already have. We could, in this manner, cut off the names of qualified men who covered unqualified, and then nobody would be able to say, "Yes; but he keeps a qualified man, does he not?" This right is exercised frequently by both the Medical Council and the Society of Advocates, and chemists will never make a fair living or be at liberty to devote time and attention to the higher and more scientific side of pharmacy until they obtain the same right. In the mean time I would say to parents and guardians, Don't send your lads to the drug business. It means hard work, long hours, arduous study, grave responsibility, and 90*l.* a year for lifting all these off the shoulders of a man who probably never made a manly effort in his life to stand in a manly position.—I am, yours, &c., R."

"Sir,—In your issue of Saturday a correspondent signing himself 'R.' pleads for a more stringent Pharmacy Act and for more extensive powers to the Pharmaceutical Society. He says the public are judging harshly and ignorantly regarding recent prosecutions by the Pharmaceutical Society; that the Pharmacy Act 'has been persistently maladministered;' and that the Judges on the bench have made adverse and unwarrantable remarks on the prosecutions.

"The Judges, no doubt, have their limitations. They are obliged to construe Acts of Parliament as they find them printed by the Queen's printers, and they are not entitled to assume intentions of the Legislature which are not expressed in words. Your correspondent may have the advantage of the Judges in knowing better what were the intentions of the framers of the Pharmacy Act. The Judges have assumed, perhaps erroneously, that the intention of the Legislature, in passing the Sale of Poisons Act, was the protection of the public against the careless and ignorant handling of poisons which were to be used as medicines. They have accordingly held that, where a properly qualified person is engaged in a drug store to dispense poisons, the requirements of the Pharmacy Act are fully met.

"In consequence of this judgment, drug stores, as your correspondent says, 'have been started all over the country by individuals who knew nothing about drugs,' but who formed companies and engaged qualified persons. This, your correspondent says, 'has been done in defiance of the Pharmacy Act, and greatly to the derogation of pharmacy both from a scientific and professional point of view.' What is meant by 'the derogation of pharmacy from the scientific and professional point of view' I take to be simply this, that medicines have, since the establishment of those drug stores, been sold at very much less prices than formerly. This is all that is meant by 'the derogation of pharmacy,' and by 'pharmacy being pulled down and kept down, and falling behind in the world of pharmacy.' People are paying less than they did for their medicines, and this is the serious state of affairs for which the people are implored to find a remedy.

"'Not the least injustice,' says 'R.,' is that 'the chemist, with his professional instincts, is brought into competition with the roaring salesman, for whom he is no fit match.' Who the 'roaring salesman' may be I am not quite sure, but I have some notion what the 'professional instincts' are which are 'cultivated at the expense of the business instincts,' and which place the man who is possessed of more professional instinct than business instinct at a disadvantage when brought into competition with others. If the 'professional instinct' is that insufferable conceit that leads men engaged in some professions to regard themselves as very much better than their neighbours, one can understand how men impregnated with this 'professional instinct' will be at a disadvantage when brought into competition with men having that business instinct which leads them to be serviceable to their neighbours. I suppose it will be 'professional instinct' which leads your correspondent to speak of the 'roaring salesman' and the 'mere salesman,' and to say of him that he can do without compunction things that the professional chemist looks down on. The chemist, according to 'R.,' has 'a keener instinct for what is in accord with the position he holds and the responsibilities he is under to support the dignity of his profession'—which simply means that the chemist has a very high opinion of himself. This high opinion is maintained greatly through ignorance of others. It is not at all likely that the general knowledge of the chemist is greater than that of printers, or booksellers, or watchmakers, or photographers, or masons, or joiners, or painters. Each of those tradesmen knows his own business, and some of them in general knowledge would surpass the chemist. The chemist is not always an Admirable Crichton; he is sometimes a person of very limited culture, of whom the best that could be hoped is that he should know his own business.

"Your correspondent thinks that a great evil arises from qualified chemists 'covering' unqualified men. But the Pharmacy Act does not sanction any 'covering.' It says it shall not be lawful for any person to retail, or dispense, or compound poisons except a qualified chemist. That means that a qualified person only has to dispense the poisons, whether it be in a shop or a store. It does not permit a qualified chemist to delegate his duties to, say, a boy of fifteen, while he is away for a week or two. Yet this is often done, and I suggest that the Pharmaceutical Society should see to it. The persons who are most frequently violating the Pharmacy Act are the chemists themselves.

"Your correspondent says that the people are judging harshly of the Pharmaceutical Society regarding recent prosecutions. I think that exceedingly likely, and I think the harsh judgment is very fully justified. There was no public interest served by the prosecution of dealers in photographic materials, even though these materials were poisonous. There was in these prosecutions a very obvious attempt to create a monopoly in favour of chemists, to the disadvantage of the public. There was a straining of the Pharmacy Act to purposes which were certainly not in public contemplation when the Act was passed. It was certainly not anticipated that the Pharmacy Act, which gave to druggists who had experience in compounding doctors' prescriptions, and to others who might acquire like knowledge, a sole privilege of compounding and selling poisonous medicines—it was not anticipated, I say, that the Act was to prevent seedsmen from selling plant dressings, or drysalters from selling such stuffs as are needed in manufacturing operations. The Pharmaceutical Society has shown, by the recent prosecutions, that the words of the Act are capable of being construed so as to needlessly harass traders all over the country. It may, no doubt, appear to the chemist very desirable to confer upon him an extensive monopoly, but it will not appear equally desirable to the general public. W. D. Macgregor."

FLASHLIGHT PHOTOGRAPHY.

[Australian Photographic Journal.]

It has been a matter of surprise to me that, while flashlight work has received considerable attention in England and other parts of the world, both from professionals and amateurs, this fascinating branch of the art seems to be almost entirely neglected throughout the Australian colonies.

There is no reason whatever why this should be so, unless it be that amateurs and others have "tried their 'prentice hands" at it and failed, or have been deterred from taking it up from an erroneous impression that it is a most difficult and expensive pastime, with far greater chances of failure than of success.

My object in these articles is to dispel any such idea, and to give such detailed and *practical* information on the subject as will enable any one with a very limited experience in photography to command success in ninety cases in every hundred.

But, first, a word as to the utility of flashlight work. I have been asked this question on several occasions, and have wondered that any intelligent person should fail to see its usefulness. One is enabled by its means to obtain photographs of places and scenes utterly impossible in any other way. Daylight is dispensed with, and is substituted by one

more actinic in its character, and far more thoroughly under the control of the operator. Portraits may be taken at night, pretty and effective family groups and gatherings secured amid all those every-day surroundings which make the word "home" so dear. What more delightful and welcome present could be received by absent members than a photograph of "those at home" by the old fireside, in the "dear old room" where the happy days of youth and childhood were spent in the long, long years ago?

If for no other reason, flashlight photography should take a leading place, and be valued highly by all interested in the art; but when, added to this, one can also secure permanent records of visits to the caves and caverns of the earth, work in the mines, and last, but not least, of the various acts and scenes in amateur and other theatrical performances—to say nothing of fancy-dress balls and the like—I think little need be said further in its favour. That it is possible, and comparatively easy, to do such things, I hope to show.

The Apparatus.

Without further remarks, I will go into the matter, beginning with the apparatus.

This, as already mentioned, need not be of an expensive character, or deter any amateur with even very limited means. Of course, should he be a millionaire, he may be as extravagant as he pleases; but, although he may thus make the work somewhat easier, I will not guarantee his pictures will be improved thereby. One of the Ilford gold-medal pictures, and the negative of which that Company made a request to purchase, was taken by means of a battery of "five penny clay tobacco pipes." The secret of success was the arrangement of the lamps and figures in the picture, and which the reader may easily repeat by following the directions given:—

For an ordinary room up to 24 × 14 feet (the size of room in above picture), procure four round sticks—straight broomsticks will do well—about 40 inches long and ¾ inch thick. Get the smith to fit a brass or stout tin ferrule 7 inches long at the end of stick No. 1, in which to place No. 2. Cut two pieces of dry and *heavy* timber, each 20 × 2½ × 2 inches. Mortise these so that they will be across each other even with the floor, in such a manner that the centre of the crossing portion is about 14 inches from the long ends. Make these to fit tightly into each other, but so that they may be knocked apart for packing purposes. A thumb-screw, going *nearly* through, will secure them when in use. Bore a hole just large enough to fit end of stick No. 1, almost—but not quite—through the centre of the cross, and put a screw-eye into each end of both pieces. Erect Nos. 1 and 2 into the hole, and, to thoroughly steady them, put a small screw-eye through ferrule into No. 1, and secure all together with stays of strong cord. Get the smith to make two *strong* T-shaped ferrules, so that the top portions fit on No. 2 so tightly that, while they may be moved up and down with an effort, they will not move of themselves. *This is important.* The other part of each ferrule must fit one end of sticks Nos. 3 and 4, which may, with advantage, be somewhat thinner than the other two. Place ferrules on No 2, so that upper cross arm will be 6 inches from top, and the other one about 1 foot below this; insert ends of the other two sticks, twist them at right angles, or more, to each other, and the support for the lamps is complete.

Should any reader have a difficulty in making this apparatus for himself, no doubt it can be supplied by photographic stock dealers, with packing box complete, at moderate cost.

I will suppose five lamps are to be fitted, although, should a less number be sufficient for the purpose, the others may be cut off by drawing the rubber tubing from them and fitting the ends with small corks to prevent the escape of air when discharging the lamps. Whether "tobacco pipes" or the more highly finished and ornamental "flash-lamps" are used, the arrangement will be the same. First mark position of *three* lamps on *upper* arm, in the middle and near each end, but clear of the ferrule. On the lower arm the best places are near the outer end and about 15 inches from upright. If pipes are used, they must be secured to the arms by means of rubber bands or fine binding wire, not too rigidly, but so that the tubing may be easily slipped on and off, yet firmly enough to prevent them "turning turtle." Should lamps be used, perhaps the easiest way to secure them is to have two stout wire spikes, soldered on each, about 1¼ inches long, and on either side. Holes to match bored through the arms will receive and hold them securely. These lamps must all be connected by small rubber tubing, similar to that used for discharging pneumatic shutters. In this manner make or obtain the following brass connecting tubes, of such thickness as to allow rubber to be tightly stretched thereon. Their several arms need not be more than 1 inch in length. One T piece, two Y shape, one F. Secure these also loosely to the frame as follows:— ⊨ to side of ferrule, holding the lower arm; one Y on this arm between ferrule and first lamp; F to side of upper ferrule; and the other Y between first and second lamps on upper arm. Connect all these and lamps together with the rubber tubing, leaving some 15 feet hanging from the lower ferrule with which to discharge the lamps. The air supply may be produced by a *large* pneumatic ball, the lungs, or a pair of bellows. In the latter case a spiral spring must be fastened between the two handles to keep the bellows inflated and prevent them collapsing and so firing off the charges before their time. They are easily acted upon by the foot when all is ready. Personally, I prefer "my own bellows" (lungs), and accordingly have the 15-feet length of the larger gas tubing, the lower limit of its ferrule being made of stouter brass to fit it tightly. In order to prevent any chance of this being dragged off the ferrule, it is well to tie a piece of string tightly round rubber, a few inches below ferrule, on stick No. 1, and loop it over the screw-eye in the same.

Charles Gruncell.

(To be continued.)

THE SPECTRUM SENSITIVENESS OF A SILVER SALT.

[Journal of the Royal Photographic Society.]

The question which it is desired to discuss is, Why a sensitive salt is sensitive to more than merely monochromatic light? We have to come back to first principles before we can endeavour to answer the question at all. The principle, or perhaps we may call it the law, involved in the first place is that, where there is absorption of light by a body, there work of some kind must be performed. When we place a slab of bromide of silver in front of the slit of the spectroscope, or, what will do as well, if we examine a spectrum through such a slab, we find that the light that it absorbs corresponds with the photographic action that takes place on a bromide plate. Of course, this may be taken as a reply to the question, if we wish; but it is my wish to carry the matter a stage further back. It may be taken as axiomatic that, when light acts on bromide of silver Ag_2Br_2, one atom of bromine is thrown out of the molecule by the light itself, and the only way in which this can be done is by the waves of light increasing the swing of the atom as it vibrates in the molecule. It is usually considered that we must have well-timed blows to increase a swing of a body, that is, that they must be perpetually given at a fixed interval of time, such time being the time of the swing. But in the case of the atom of bromine which is swung out we have an almost infinite number of waves of different periods which will affect it. Thus, from the yellow to ultra-violet, we have a whole octave of waves which affect the bromide of silver. It looks as if that what is usually accepted as a necessity is not so. The explanation, however, is not far to seek. It can only require a certain amplitude (the amplitude which is sufficient depending on circumstances external to the molecule, such as the avidity of a neighbouring substance to attract the atom and to annex it) to cause it to swing beyond the sphere of molecular attraction, and, if this is attained, any further increase in motion is superfluous as far as that atom is concerned.

The next point to consider is, whether such an increase in motion or swing can be given by waves which are not absolutely in tune with the swing. A very simple physical experiment shows that such can be the case. Swing two pendulums side by side on the same knife edge; let one be a cord with a small weight attached, and the other a heavy weight with a rigid attachment. Let them, first of all, be of the same length. When the heavy weight is set in motion, the flexible pendulum will take up the motion and swing with it side by side, and as long as one swings the other will swing. Let, however, the flexible pendulum be slightly shorter than the rigid pendulum, and the motion of the former will be increased at first, and then, after a long interval, die away, and again increase, and so on, this increase and diminution depending on the relative lengths of the two pendulums. When the swing of one is in the opposite direction to the swing of the other, the swing of the light pendulum will gradually diminish until it comes to rest, when it will commence to swing again with the heavy pendulum. Supposing the flexible pendulum to be an atom acted upon by a wave motion with which it is not absolutely in tune, it will increase the amplitude of swing at first, and, if the amplitude it takes is sufficient to take it out of the sphere of the attraction of the molecule, it will not matter that the two motions are not exactly of the same period. We eventually come to periods of vibration which are so different that the atom can never be ejected, and here we have no sensitiveness, as it is called. Absorption indicates the same thing in a visible manner, so absorption and sensitiveness go hand in hand. It seems to me that, broadly, this is a view that accounts for atomic motion answering to such a large part of the spectrum, as we know it does. This view may be enlarged in various directions to account for phenomena which I have called attention to in the last three years or so. The increase in sensitiveness in a higher temperature of the silver salt, the sluggishness of the response to feeble light, and also to very intense light, can be traced to this cause, and I propose shortly to give a theory based on what has just been indicated.

Captain Abney, C.B., D.C.L., F.R.S., P.R.P.S.

ON THE RÖNTGEN RAYS.

[Extract from the President's Annual Address to the Victoria Institute.]

For a very long time it has been known that an electric discharge passes more readily through tolerably rarefied air than through air of greater density, and so with other gases. If we have a longish closed tube, provided with electrodes at the ends by means of platinum wires passing through the glass, if the air be tolerably exhausted from it, an electric discharge passes, comparatively speaking, freely through it, forming a beautiful skein of light, if I may so speak, and under certain circumstances that skein of light is divided into strata in a very remarkable manner. These strata fill the greater part of the tube from the positive electrode, or anode, as it is called, till we get nearly, but not quite, to the negative electrode, or cathode. There is a dark space separating the end of the positive discharge which, as I said, under suitable conditions and sufficiently high exhaustion, shows stratification from a blue glow enveloping the negative electrode or part of it. The luminosity about the cathode is somewhat indefinitely bounded on the side of the stratification.

When, however, the exhaustion is carried still further, at the same time the strata become wider apart, and the luminosity recedes from the cathode and expands, forming a sort of glowing halo much more sharply defined on the inside than the outside; in that respect resembling the ordinary luminous halo—not the corona—occasionally seen round the moon. We have here, then, these two dark spaces; one outside the halo, where the luminosity gradually fades off, and another dark space on the inside, where the luminosity is more sharply defined, and which reaches to the negative electrode.

Now, it is the phenomena in connexion with this second dark space that I have more particularly to bring before you. As the exhaustion is rendered higher and higher, the inner dark space gets wider and wider, until at a sufficiently high exhaustion it fills the whole tube or bulb. Mr. Crookes has worked more especially at this subject, and, indeed, the tubes which are now used for the production of the Röntgen rays are generally called "Crookes' tubes." I have seen in some of the foreign periodicals the word "Crookes" used to signify one of these tubes. Mr. Crookes' researches in very high vacua led him up to that most remarkable instrument, the radiometer, the nature of which led us to form clearer conceptions than we had hitherto done, of the nature of the motion of molecules in gas; or, rather, when the theory of the radiometer was made out, presented us, as I may say, with a visible exhibition of the thing in actual working.

Now, these researches, which led Mr. Crookes to improve his vacuum, naturally led him to examine the electrical phenomena produced by excessively high vacua.

I have said that it was with the second or inner dark space that I had chiefly to do. When the exhaustion is sufficient, that fills the whole tube.

Now, what takes place in this dark space? Suppose we interpose a screen, such as a plate of mica with a hole in it. A portion of the discharge from the negative electrode goes through that hole and continues onwards in a straight course until it reaches the wall of the tube. When it reaches the wall of the tube (I will suppose the tube, as it is called, to be made of German glass) it produces a greenish yellow fluorescence, or phosphorescence of very brief duration. I need hardly say that, if you do not limit what comes from the negative electrode by the screen with a hole in it, you get a broader beam, which affects the glass wall over a larger space.

Now, what is it that proceeds from the negative electrode towards the glass, and, when it gets there, produces this phosphorescence? Is it light, or is it matter?

One remarkable circumstance connected with this *something* is, that you can deflect it in its course by a magnet. If you present a magnet to a ray of light, it does not deflect it at all; but this *something* is easily deflected by a magnet, even by a tolerably weak magnet. Mr. Crookes found that in addition to that property, if this discharge of a something fell upon one side of a very light fan formed of thin, split mica, and delicately mounted so as to enable it to spin readily, it sent it spinning round; and he believed that the nature of that which we have here to do with is, that it is a stream of molecules. Nobody, I suppose, denies that there is matter propelled; but there has been a considerable difference of opinion as to whether the matter propelled is of the essence of the phenomenon, or whether it is something merely accidental. Mr. Crookes held that it was of the essence of the phenomenon, and that we had here, really, a stream of molecules, and I must say, for my own part, I believe he was right. But some foreign men of science hold that the projection of matter is altogether a secondary phenomenon, and that what comes through this small hole is really only a process which goes on in the ether—something so far of the nature of light, but yet differing from ordinary light most markedly in the property of being deflected by a magnet. To illustrate what I mean by saying something secondary, Professor Wiedemann, who holds the opinion that it is of the nature of light, or a process going on in the ether, imagines that the projection of matter has no more to do with the phenomenon than the path of a cannon ball has to do with your hearing the sound of the cannon. I think, myself, that it has a great deal more to do with it than that. However, I will leave that matter for the present to pass on to some researches which led up to the remarkable discovery by Dr. Röntgen.

In Germany, Professor Lenard made a very remarkable series of experiments in what the Germans call, and what we may call, the cathodic rays, and which he believed to be actual rays, and not streams of molecules sent from the cathode. In order to produce these rays, as I will call them, you want a very high vacuum. If, however, you make your vacuum too high and too nearly perfect, you cannot get the electric discharge to pass through it. A perfect vacuum appears to be a non-conductor, and, if you attempted to make the electric discharge pass through it, it would go, by preference, on the outside from one electrode to the other, so that you cannot work directly with anything too nearly approaching to a perfect vacuum. But it is a very remarkable thing, though Lenard, I believe, was not the first to discover it, but Hittorff, that these cathodic rays pass, or appear to pass, through a plate of aluminium which is perfectly impervious to light, or even to the ultra-violet rays, which we know by their effects, though we do not see them directly; so that you may have these cathodic rays at one side and something of the same kind at the other. Lenard constructed an apparatus commencing with a Crookes' tube, in which there was very high, though not too high, exhaustion, with a cathode which was either flat or cup-shaped at one end, and opposite to that, in the part where the cathodic rays would strike the glass if it were there, instead of glass it was closed by a thin plate of aluminium foil, so thin that it would support the atmospheric pressure although it was impervious to air. But as a continuation of that tube he had another tube, which was also capable of exhaustion. The two tubes had glass tubes leading from them to the same air pump. There was communication with the air pump and communication between the two tubes, and you could exhaust them together, and the pressure would be so far reduced that the aluminium plate was strong enough to sustain the reduced pressure. They were both exhausted together until a suitable exhaustion was produced for the production of the cathodic rays in the first tube, and then the connexion between the two tubes was intercepted, and the exhaustion of the second tube, which was kept connected with the air pump, was continued for several days, until, as near as he could get it, there was nothing at all in the way of gas left in it. What was the result? In the first tube the cathodic rays were produced by the electric discharge. They fell on the aluminium foil at the end, and then there was a continuation of cathodic rays in the highly exhausted tube—the vacuum tube I will call it—and these went on as if they had been rays of light. They were deflected by the magnet just like the original cathodic rays.

Now, at first sight, that looks very much as if you had to deal with actual rays, which passed through the aluminium foil, just as rays of light would pass through a plate of glass. But I think the real explanation of it is altogether different. I believe it to be of this nature. First, I will use rather a gross illustration, in order that you may the better apprehend the nature of the other explanation that I am about to bring before you. Suppose that I have a row of ivory balls in contact, such as billiard balls, and that another similar ball strikes the first of these. The result is that the last of the balls is sent off, and the striking ball and the intermediate balls remain approximately at rest. Now it is conceivable that something analogous to that may take place as regards these so-called cathodic rays, supposing they are not rays at all, but streams of molecules. It is conceivable that the molecules proceeding from the cathode or negative electrode of the first tube, be they of residual gas, or aluminium, or platinum, might fall upon the thin aluminium plate which forms a wall between the two tubes, separating the one from the other, and that that would give rise to molecular discharge in the second space, although the actual moving molecules never passed through the wall. As I say, that is a rough illustration—rather a gross and material illustration—to enable you to understand more clearly the view I have to bring before you.

I have said that the so-called cathodic rays are easily deflected by a magnet. Now, we know from other experiments that if a body sufficiently charged with electricity is in rapid motion, and that motion takes place in a magnetic field, the body tends to be deflected. This looks, therefore, very much as if these cathodic rays are actually streams of molecules, which, being highly charged electrically, and of almost inconceivable minuteness, would be deflected by a slight magnetic force. Now, if these highly charged molecules come to strike on the aluminium wall which separates the two tubes (which are end to end) from one another, it may be that an electrical action goes on which resembles very much what electrolysis is supposed to be according to the views of Grotthus. I shall not have time to enter into an explanation of that now, for it would lead me too far from the subject; but several present will, no doubt, understand what I mean when I refer to the views of Grotthus. The molecules then impinge on the wall, and give rise to a projection of molecules from the second side of the wall, but the latter are not the same molecules which impinged on the first side of it. Whether the molecules projected in the second tube come from a very minute quantity of residual gas, or whether they are derived from the aluminium wall itself, from which they are torn, as it were, does not signify for my purpose. We have here, you see, a conceivable mode of emitting these so-called rays in this way, simulating the transmission of a ray of light through a plate of glass, though it is no ray at all that we are dealing with. I confess I think that that is the true view of the action which

akes place; but Lenard himself believed that the cathodic rays were, as he said, processes in the ether. By means of the first tube used alone, as was done in the first instance, but closed with a "window" of somewhat thicker aluminium foil, so as to sustain the atmospheric pressure, he was able to receive the cathodic rays which came from the second surface of the aluminium foil in air, where he could examine them at pleasure, using for their detection sometimes a phosphorescent or fluorescent screen, sometimes a photographic plate. He found that, under these conditions, they were quickly deflected from their original direction and dispersed, so that they could not be traced far, just like rays of light in a turbid medium, such as water to which a little milk has been added, whereas in a subsequent series of experiments, to which reference has already been made, in which the cathodic rays were received into a second tube, the dispersion became less and less as the exhaustion proceeded, until, at the highest attainable approach to a perfect vacuum, the dispersion almost disappeared, and the rays were traced right onwards for a metre and more, and that without being enlarged by diffraction, as would be the case with rays of light.

Lenard mentioned incidentally that these cathodic rays, as he supposed they were, were able to pass through the hand even. He missed the discovery of the X rays because he had, I may say, the cathodic rays too much in his head, and attributed the whole effect on either side of the wall to the cathodic rays. Really the effect is due in part to the cathodic rays, and in part to the Röntgen rays, the existence of which he was not aware of. They cannot be distinguished merely by their effect on a fluorescent screen or on a photographic plate, since both these recipients are affected by the rays of both kinds.

Such was the state of things when Röntgen made his remarkable discovery. According to an account which I saw in one of the newspapers (we cannot vouch for the truth of everything we see in the newspapers), the discovery was made in the first instance accidentally. I cannot give you more authentic information than that, but he had been working with a Crookes' tube, and he observed that a photographic plate, enclosed in the usual case in which these plates are enclosed when you want to protect them from light, showed, on development, certain markings on it; so he put the whole apparatus, as it had been, with a photographic plate in its case in the same position as before, and the thing was repeated. This is according to the account in the newspapers. A very remarkable discovery was the result. He found that rays were capable of coming out of some parts of a Crookes' tube which had the remarkable property of passing through substances that are opaque to ordinary light, and opaque even to the ultra-violet with which we were previously acquainted. They pass freely through black paper, through cork, wood, or even through the flesh of the hand, though less freely through the bones, so that, by simply laying his hand upon the case containing the photographic plate, he actually got a photograph of the bones of his hand.

Well, what is the nature of these rays, and whence do they come? As Röntgen said in his original paper, a slight examination shows that they have their origin in the part of the Crookes' tube opposite to the cathode, and which is rendered phosphorescent by the discharge from the cathode.

The rays, however, which come from this part of the tube, and which appear to have their origin there, differ utterly in some respects from the so-called cathodic rays. If you isolate a portion of them, you find that a magnet has no action upon them; unlike the cathodic rays, they proceed onwards without deflection, just as if the magnet were not there. Like light, they proceed in a straight course, but these rays are able to pass through a variety of substances that are opaque to ordinary light, while, on the other hand, they are stopped by other substances which let light freely through. That, however, does not prove that they are not of the nature of light. You may have, suppose, a red glass which is opaque to green rays, but let red rays through very freely, so that as regards merely the fact of the X rays being stopped by substances transparent to light, while they pass more or less freely through other substances which are quite opaque to ordinary light, that establishes no greater distinction than exists between green and red light. Are they, then, of the same nature as light?

The X rays have some very remarkable properties, by which they appear at first sight to differ *in toto* from ordinary light. They pass with either no refraction, or excessively small refraction, through prism-shaped bodies, which we know rays of light do not. They suffer hardly any, if any, regular reflection, unless perhaps at a grazing incidence.

Röntgen himself, in his original paper, dwelt on these peculiarities of the new rays. He formed a prism of aluminium, with which he attempted to obtain deviation of the new rays, but the experiment showed that, if there were any deviation at all, at any rate the refractive index could not exceed 1·05. He speaks of the rays not being apparently capable of regular reflection, but he brought forward experiments which show that, in a certain sense, they appear to be capable of reflection.

A photographic plate with the sensitive surface downwards was placed in its case under a Crookes' tube, and immediately under the plate, and inside the case, were placed portions of different kinds of metal which would be capable of reflecting back the rays on to the sensitive surface if they admitted of reflection; and it was found that the plate was much more darkened over certain of those metals than where the metals did not exist. There was very little darkening over aluminium, and a great deal of darkening comparatively over platinum. This indicated that some effect was produced, though the greater part of it is not one of regular reflection. He conceived the effect to be one of reflection such as you might have from a turbid medium.

There is, however, another mode of explanation, which seems worth considering, viz., that the Röntgen rays, falling upon the metal, throw the molecules into a state of vibration, which they communicate to the ether by a sort of phosphorescence or fluoreacence of X light, so that the rays which come from the molecules, though perhaps not of exactly the same nature as the X rays that fell upon them, still have enough of the "X" quality about them, whatever that is, to enable them to get through objects which are opaque to ordinary light.

Lord Blythswood, who has worked a great deal with the Röntgen rays, has written a paper, which was communicated to the Royal Society by Lord Kelvin, in which he establishes a minute regular reflection of those rays from speculum metal at an angle of about 45°. Two plain specula were placed side by side so as to receive at that angle the X rays coming from a Crookes' tube, and a duly protected photographic plate was placed in such a position as to receive the regularly reflected rays, if there should be any. The developed plate appeared to show a slight indication of the junction between the mirrors, and that the appearance was not illusory was shown by Lord Kelvin, who made measurements on the image, and compared the results with what they ought to be on the supposition of a regular reflection. The indication was so faint that I could not myself perceive it (I have not seen the negative, but only positive copies), but Lord Blythswood has given me some positive copies of a negative which he subsequently obtained by reflection from a concave speculum at a small angle of incidence, and which show for certain a minute regular reflection of X rays, while, at the same time, they prove that the quantity of X light returned by regular reflection is extremely small compared with that which comes from the mirror by some different process.

SIR G. G. STOKES, F.R.S.

(To be continued.)

LABORATORY USE OF ACETYLENE.

Now that acetylene has come so much in prominence, an instance of its use in a laboratory, which possesses no gas supply, may be an encouragement to any one similarly situated. Long doomed to the use of spirit lamps, "benzoline roarers," and the like, says Mr. A. E. Mundy in *Nature*, the cheap production of acetylene has come as a great boon to us, and is now in regular use for blowpipe work. The apparatus in use consists of an aspirator holding about fifteen litres, permanently connected with a water supply, and possessing a ¼-inch aperture exit tap (the water flows in from below to minimise absorption); at the top a three-hole rubber cork carries an upright pipe passing through the table, which serves for filling the aspirator with gas, or using the gas on the table, a second pipe goes to the blowpipe, and a third carries an open mercury manometer. For filling the jar, the calcium carbide is placed in a four-ounce bottle, closed by a cork carrying a small separating funnel from which the water drops; the gas passes to the aspirator through a wide glass tube, which acts as a reversed condenser, returning most of the water vapour to the bottle. With the large exit to the aspirator the gas can always be collected under a reduced pressure of several cm. of mercury, which quite provides against any sudden rushes of gas; the operation takes some ten minutes, and requires practically no attention.

In using the gas, the water is turned on with all taps closed for a few seconds, to correct any reduced pressure caused by absorption, as shown by the gauge (this is very slight indeed), and then the gas tap fully opened, and the flame regulated entirely by the water entrance. To bring the gas into use takes hardly any longer than with an ordinary gas blowpipe. A good fusion on platinum foil (*e.g.*, $BaSO_4+Na_2CO_3$) may be affected by using about one litre of the gas. We have used the apparatus for about two months, and I recently discovered that some of my junior workers did not know what acetylene smelt like, which speaks well for it, if not for them. I am hoping to introduce the gas on to the benches, if the difficulty of the enormous quantity of air required to produce a non-luminous flame can be overcome.

The Inquirer.

*** *In this column we from time to time print questions that may be addressed to individual contributors to our pages, or such as are sent to us with the view of eliciting information from a variety of sources. We invite the co-operation of our readers in rendering this feature of the* JOURNAL *useful and instructive.*

FINISHING BROMIDE ENLARGEMENTS.—J. E. Brown inquires: "1. What are the best colours for finishing bromide enlargements developed with iron? 2. The address of Zuccato & Wolff, Typograph makers, London."

IMITATION OPALS.—W. Beaton writes: "I cannot, in our town, readily obtain opal glass, and when I can it is not fit for photo-

graphic use. I have heard of substitutes, in the form of a gelatine emulsion of barium sulphate or some such substance, but I cannot succeed in getting a perfect film. I have tried making an emulsion with Epsom salts and nitrate of barium in gelatine, but the result is as coarse as sand paper. Can you help me with a formula or any advice as to how to proceed?"

RETOUCHING MEDIUM.—In reply to "Portraitist" I should like to point out one cause of retouching media not giving a good tooth. It is frequently recommended to apply the medium with the finger tip. I find it much better to apply by means of a bit of clean rag smoothly folded over the finger tip, thus preventing the greasy moisture from one's hand mixing with the medium. The slight moisture mentioned is quite sufficient to repel either graphite or water colour. I shall be pleased to send "Portraitist" a sample of a really reliable medium, on receipt of his address, with postage.—RETOUCHER.

RETOUCHING MEDIUM.—If "Portraitist," who asks for a retouching medium, will forward me his address, I will send him a bottle of a kind I use myself and find quite reliable. I cannot help thinking his difficulties arise from leaving too much medium on the negative. It should be spread with the tip of the finger, working in a circular direction until it is nearly dry, and finished by stroking with the finger in straight lines *until it is quite dry*. All retouching should be done upon the film, and protected with varnish. If necessary, more work can be put on the top of the varnish, but this should always be avoided if possible, and the medium put only on the part to be retouched, as it always has a tendency to attach dust, &c., to the surface of negative. My own negatives are first coated with celluloid varnish thinned with acetone and spirit (methylated). After retouching, the negative is varnished a second time with a good shellac varnish. It can then be left out in the rain without fear of injury.—HAROLD BAKER.

DOUBLE FIXING OF PRINTS.—IN DOUBT says: "I have seen it recommended to employ two separate fixing baths, both for negatives and prints, in order to ensure their perfect fixation. The sulphocyanides have also been put forward for fixing prints, but are stated not to effectually do the work when used alone, although they are supposed to tend less to fading than hypo. This being the case, how would it answer to use a hypo bath first, and follow this, after rinsing the prints in water, with one of sulphocyanide? Would not the latter probably remove the ill effects of the hypo?"—We cannot see any advantage over two hypo baths, while there are several reasons that can be urged against the sulphocyanide, the chief of which is that a solution sufficiently strong to be of any use in fixing, especially negatives, would soften or dissolve the gelatine and ruin either negative or print.

INSENSITIVE COLLODION EMULSION.—N. B. B. writes: "I had intended to point out, when writing on this subject recently, that it is often said that a bromide emulsion film that has been treated with a wash of weak iodide of potassium is perfectly insensitive to light. This is far from being the case unless the soaking is very prolonged and a considerable quantity of solution used. The insensitiveness depends upon the total conversion of the silver bromide into iodide, the latter salt when formed in the presence of excess of soluble iodide being, it is well known, insensitive to light under ordinary conditions. But a weak solution of iodide of potassium—by which I mean a solution of five or six grains to the ounce—will take a very long time to completely convert the whole of the bromide, and consequently, more especially if well washed afterwards, such a film will be very subject to fog if exposed to light. The only plan is to use a fairly strong solution, though not sufficiently strong to dissolve out the silver iodide when formed."

Our Editorial Table.

SAMPLES OF CHRISTMAS CARDS.

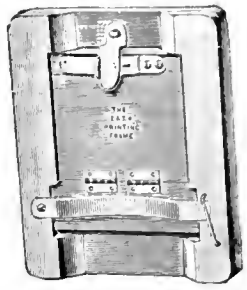
Wilfred Emery, 3, Soho-street, W.

A FEW samples of Christmas cards, with photographs mounted on them, reach us from Mr. Emery, who is supplying dealers and stationers. The cards are neat and tasteful. Mr. Emery undertakes to make up customers' negatives as Christmas cards for publication or otherwise. His prices appear to be very moderate.

THE "EASY" PRINTING FRAME.

William Tylar, High-street, Aston, Birmingham.

BY rotating the small clip shown at one end of the cut, a portion of the back of this frame, amounting to about two-thirds, is released, thus allowing the photographer to examine nearly the whole of the print, which is securely held by a spring clamp at the other end



of the frame. Hence there is no risk of movement. The frame embodies a useful idea, and should be welcome to both professional and amateur printers.

A VISIT TO THE CARLTON HILL CAMERA WORKS.

By R. W. STARR. Leeds: J. Houghton.

THE Carlton Hill Camera Works of Messrs. Watkinson & Co. form the subject of a brief, but clearly written, description from the pen of Mr. R. W. Starr, who pleasantly guides the reader through the workshops and other premises of the enterprising firm, whom many visitors to the Leeds Convention will, doubtless, keep in remembrance. By way of illustrations, twelve capital collotypes are given from which a good bird's-eye view is obtained of the works. The booklet is an effective reminder of Messrs. Watkinson's enterprise.

THE "AXE BRAND" CHLORIDE OF GOLD.

Fuerst Bros., 17, Philpot-lane, E.C.

IN forwarding us a sample tube of the "Axe" brand of gold chloride Messrs. Fuerst Bros. inform us that it has met with the general approval of both professional and amateur photographers. It is supplied in tubes of fifteen, thirty, and sixty grains (either bulb or cylinder shape) and the quantity of pure gold in the compound is stated on the label.

We employed some of the gold sent us in toning both collodion and gelatine prints, using phosphate of soda therewith, and found the tones we obtained all that could be desired. We note that the "Axe brand is listed as of English make.

PHOTO-ENGRAVING MADE EASY.

By JOHN LEMANE. Sydney: (N.S.W.), Harrington & Co., 66, King-street.

THE author outlines the half-tone process in the course of some thirty-six small pages. It is such a book as should be found useful by a beginner, all theoretical considerations having been avoided. Mr. Lemane is familiar with his subject, which he treats with clearness and brevity.

News and Notes.

WE are sorry to learn of the death of Dr. Paul E. Liesegang, of Düsseldorf which took place on the 5th inst., in his fifty-ninth year.

MESSRS. PERCY LUND & CO., LIMITED, will in future be known as Percy Lund, Humphries, & Co, Limited. The constitution of the Company remains exactly as before.

MR. J. E. THORNTON, of the Thornton-Pickard Manufacturing Company, was married, on August 24, to Miss Heaton, at Southport. There was a large gathering at the ceremony, and a reception was subsequently held.

ON Wednesday, the 2nd inst., Mr. Austin Edwards, the film-manufacturer, gave a dinner to his *employés* at the Holborn Restaurant, the party afterwards adjourning to the Gaiety Theatre to witness the performance of *My Girl*.

THE PHOTOGRAPHIC CLUB.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock on Wednesday evening, September 16. The subject for discussion will be *Fixing Prints*.

MR. AUSTIN EDWARDS, of Willoughby-lane, Park, Tottenham, informs us that a Frena camera will be awarded monthly in competition for the best film negative on an Austin Edwards' film. The conditions and the necessary form may be obtained of Mr. Edwards at the address given.

LEWISHAM CAMERA CLUB.—An Exhibition of members' and past members' work will be held on September 28 and 29 in the Lecture Hall of the Lewisham High-road Congregational Church. Past members who have not received a notice are requested to at once communicate with Mr. H. M. C. Sprunt, 192, New Cross-road, London, S.E.

AN ART WRANGLE.—"When it comes to art encouragement," said the picture-hook, "I think I may modestly assert that a great deal depends upon me." "Pooh!" said the gimlet, "you yourself are absolutely dependent on the picture moulding. Now, I——" "Dear, dear," cried the screwdriver, "what a bore you are. Not one of you can compare in an artistic sense with my friend, the corkscrew, who is absent this evening attending an opening on the avenue." "What does he know of art?" said the tack-hammer. "What does he know of art?" repeated the screwdriver, scornfully. "You probably forget that he learned to draw when a mere infant, and that he has an unsurpassed pull in all well-regulated studios. What does he know of art, forsooth?" —*Detroit Free Press.*

PHOSPHORESCENCE AND X RAYS IN THE GEISSLER AND CROOKES' TUBES.—We have communicated to the Acc. di. Sc. fit. e mat. di Napoli (February 25, 1896) that a spark introduced into the circuit of a Rubmkorff coil and of a Crookes' tube modifies the action of X rays. We call positive-air spark the spark introduced between the positive pole and the tube, and negative-air spark the spark introduced between the negative pole and the tube. With rigorous experimeuts we have found that a positive-air spark increases the effect of X rays and a negative-air spark diminishes it. By means of various arrangements, we have also obtained the Crookes' phosphorescence and the X rays from the Geissler tube. The following arrangement (bipolar inductive) gives the best resnlts:—On the outside of a Geissler tube are glued two pieces of tinfoil, which are connected to the poles of an induction coil. These are also in communication with a graduated spark stand. When the coil acts, at every spark passing between the balls of the spark stand, a discharge passes through the tube and illuminates it. Contemporarily on the wall opposite to the positive tinfoil appears the Crookes' phosphorescence, which is accompanied by the X rays. The Geissler tube in this side is transformed, momentarily, in a Crookes' tube, while it maintains in the other regions the properties of the low-vacuum tubes. In this arrangement the phosphorescence and the effect of the X rays depend upon the length of the air spark. There is a determined length, which produces the greatest action. When it is unnecessary to employ Crookes' tube to obtain X rays, the Röntgen phenomena may be produced by using low-vacuum tubes without electrodes. Our arrangements are, besides, used to concentrate the cathodic rays, and, consequently, the phosphorescence and the X rays, in a restricted side of a Crookes' tube. The concentration was also obtained by employing a magnetic field.—F. CAMPANILE and E. STROMEI, in the *Electrical Review.*

LANTERN-SLIDE MAKING ON THE DECLINE (?).—A friend draws our attention to the following curious paragraph in the *Daily Telegraph:* "One by one the recollections of childhood seem to be disappearing. Tastes have changed, and many institutions that were dear to the hearts of youngsters a quarter of a century ago no louger receive popular support. Among these must be classed what was once the magic lantern, but what is nowadays a costly scientific instrument, the very mechanism of which is enough to alarm the purchaser before he has dared to inquire the price. Lantern-slide making—an industry without which all the phantasmagoric apparatus ever invented is of little use—is on the down grade, and the only explanation is that the public demand for this form of combined recreation and instruction has diminished within recent years. Formerly, those engaged in this business had societies of their own, which assembled week by week to engage in social intercourse and the comparison of pictures. One of their last survivors has just been disbanded, simply because its members have no fresh slides to show one another, and it is idle to attempt to be cheerful at night when one has no business to transact during the day. The decadence of the magic lantern is an event that will be regretted by many who are not concerned with its commercial aspect at all." Evidently our contemporary soon found out that it had been deceived, for in a subsequent issue it had the following apologetic explanation: "It is interesting to learn that a West-end society of magic-lantern slide-makers that was recently disbanded failed rather from inanition than from adversity, and that, with the approach of the long evenings, an attempt will be made to resuscitate it into renewed vigour. Although scientific men have rather terrified some people by the elaborate names and the still more complex mechanism of the old-fashioned schoolroom favourite, in its simpler form the magic lantern is, we are assured, still cherished by the young. One London dealer alone had as many as fifteen thousand slides out on hire at one time last season, and the prospect for the coming winter is regarded as full of promise." Will some correspondent oblige us with particulars of the "West-end Society of Magic-lantern Slide-makers?"

THE "CLERK OF THE WEATHER."—The *Windsor Magazine* for September gives an illustrated account of the Offices of the Royal Meteorological Society, and throws much light on how the weather forecasts are made. "The connexion of the Office with the meteorological world outside is established by a single Wheatstone instrument and a private wire linking it with the central telegraph office in St. Martin's-le-Grand, through which it last year received information from about 250 districts in all parts of the British Isles. The Royal Meteorological Society supplies information in addition from some thirty of its own stations at carefully selected points, with its own officers in charge of them. From these and other trustworthy observers—persons in lighthonses and observatories, coastguard stations, and so on—there are received in Victoria-street sixty reports every morning, seventeen every afternoon, and twenty-nine every evening. The principal daily report—that transmitted at eight o'clock in the morning—is required to state what was the height of the barometer at six o'clock the previous evening, the force of the wind, the temperature, and the general character of the weather. It should also state the height of the barometer, direction and force of wind, sea disturbance, weather, and temperature by dry and wet bulb at the actual time of transmission, and it must say also what have been the maximum and minimum thermometer readings, and the total rainfall during the preceding twenty-four hours. If we stand by as they come clicking and rattling in by the Wheatstone, we shall find that they are not very suggestive of weather. What they really do present to the inquisitive onlooker, however, may be something like this: '97622 09549 96228 06253 50046 64485.' That may be the whole message, or a few words may be added, such as 'Gale began at seven p.m., ended at five a.m. Sky still overcast.' The numbers, however, constitute the main report, and in the morning they always consist of six groups, each of five figures. The first group relates to the barometer and the direction of the wind at six o'clock the previous evening, and will be understood to mean that the mercury stands at (2)9·76, and that the wind, as indicated by the 22, is W.S.W. Similarly, the second group refers to the force of the wind, the weather, and the temperature of the air. The 09 will be interpreted to mean that at the same hour the previous evening a strong gale was blowing. The figure 5 means that it was raining, and 49 was the temperature by the dry-bulb thermometer. The next two groups of figures give similar information for the time at which the message was dispatched, and the two following groups, read in accordance with the code, give the reading of the wet bulb: rainfall for the preceding twenty-four hours, the maximum and minimum temperature for the same period, and the condition of the sea at the time of dispatch."

Patent News.

THE following applications for Patents were made between August 24 and August 29, 1896:—

LENSES.—No. 18,723. "Improvements relating to Double Objectives for Photographic purposes." Complete specification. F. R. VON VOIGTLÄNDER.

CAMERAS.—No. 18,822. "Improvements in Photographic Cameras." L. J. R. HOLST.

FLUORESCENT SCREENS.—No. 18,859. "Apparatus connected with the use of Fluorescent Screens and Röntgen or X Rays." E. PAYNE.

DEVELOPING DISH.—No. 18,773. "Developing Dish for Photographic Films." Complete specification. H. O. BLAKER.

SCREEN KINETOSCOPY.—No. 18,884. "Improvements in Apparatus for Photographing Objects in Motion and for Reproducing or Exhibiting the Photographs of such Objects." Communicated by C. W. Schmidt and A. Christophe. G. F. REDFERN.

STEREOSCOPE.—No. 18,904. "An Improved Photograph-changing Stereoscope." Complete specification. W. A. FRIED.

SCREEN KINETOSCOPY.—No. 19,107. "Improvements in or connected with means for taking Photographs in Rapid Succession and similarly projecting them upon a Screen." H. C. FLEMING.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK

September.	Name of Society.	Subject.
14.....	North Middlesex	*Enlarged Negatives by Means of Carbon Transparencies.* C. Beadle.
15.....	Birmingham Photo. Society .	Excursion: Gloucester. Leader, R. C. Cartwright.
15.....	Brixton and Clapham	Ordinary Meeting.
15.....	Gospel Oak	*Toning and Manipulating Solio Printing Paper.* W. J. Ramsey.
15.....	Hackney	Open Night.
16.....	Borough Polytechnic	Open Night.
16.....	Photographic Club	Fixing Prints.
17.....	London and Provincial	*What is the Best Way of Mounting P.O.P. Prints?* E. H. Bayston.
19.....	Borough Polytechnic	Excursion: Purley and Caterham.
19.....	Leytonstone	Excursion: Waltham Abbey. Leader, G. U. Haslam.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

SEPTEMBER 3,—Mr. R. Beckett in the chair.

A letter was read from the Hon. Secretary of the Photographic Club, inviting the members of this Association to join them at their annual outing at Hampstead this year.

Mr. ASHBY showed a much faded print of about four years old which he wished to copy or restore, and wanted to know how to set about it.

Mr. HADDON thought it might be possible to restore it by converting the silver into chloride and developing, but it was rather risky.

The CHAIRMAN said perhaps intensifying with uranium would be of use, although he could not speak from experience. The reason was that you would get a red image, which could then be copied in the camera.

Mr. HADDON said that would do only where metallic silver was present, but it was a question whether there was any metallic silver to act upon.

Mr. W. D. WELFORD read a paper on—

PHOTOGRAPHIC EXHIBITIONS AND PROGRESS.

He thought a manifest improvement followed competition, and advocated the continuance of Exhibitions and competitions. Most of the opposition came from those who did not exhibit at all, but as soon as a man begins to exhibit his opposition ceases. The main factors in the pictorial progress of photography were Exhibitions and competition. Some cry out that there are too many Exhibitions. This may apply to London, but not, he thought, to the

country dis'ricts. He suggested that, as far as London was concerned, the Pall Mall, Salon, and the larger shows would answer all the educational purposes. As to whether Exhibitions had seen their day, he thought the reverse. All the best photographers of the day have commenced by competing at Exhibitions, and most of them recognised the progress they had made, and do not clamour for abolition. Some, on the other hand, as soon as thirty or forty medals had fallen to their share, thought the need for them at an end. Speaking about the merits of some of the prize pictures at Exhibitions, he said, although we may not agree with the Judges in some cases, a good deal could be learned as to why our own productions had not been medalled. With reference to the attacks levelled at medals, he said it was quite an individual taste what shape awards should take. Regarding the practice at some shows of offering very large numbers of medals, for all that, the Royal Photographic Society's medal was none the less precious. Money was not now, he considered, so important, and brains stood a better chance. Nothing had done so much for the advance of photography as the oft-despised Exhibition.

The CHAIRMAN asked whether they were technically producing better photographs than in years gone by in consequence of these Exhibitions. He thought the technical as well as the artistic sides deserved a lot of attention, and that the prize-winners would be found to devote a considerable amount to both. He deprecated the large increase in the number of classes.

Mr. FRESHWATER thought it a great incentive to exhibit when awards were given for the best work, and expressed the opinion that the Royal Photographic Society's medal was far in advance of anything offered to competitors in value.

Mr. WELFORD said for years technical merit had ruled the roost, and they had never tried for anything but that, but now they were going beyond. The more one tried to improve his picture artistically, the more technical knowledge he acquires. The most artistic photographer was really the most technical. In regard to the often-suggested course that Judges should give their reasons for awards, he did not think it their duty. They only had to give their judgment and go home.

Mr. MACKIE asked Mr. Welford's grounds for saying that medals used to be given solely for technical excellence, and strongly disagreed.

Mr. WELFORD asserted that there was no artistic merit thirty years ago.

Mr. MACKIE thought it a question of the fashion of the time, and that many of the pictures taken at that time would secure medals now *artistically*.

Mr. WELFORD said they might take them *technically*, but not artistically.

PHOTOGRAPHIC CLUB.

SEPTEMBER 2, Mr. Thomas Bedding in the chair.

The HON. SECRETARY announced that Mr. Horsley Hinton would deliver a lecture on Wednesday, October 7, upon *Pictorial Photography*. The lecture would be illustrated by lantern slides.

Mr. BRIDGE also announced that Mr. Snowden Ward would give the first Travellers' Night on September 30. Subject, *Shakespeare at Home*, illustrated with lantern slides.

Mr. Drage showed some photographs by Mr. Jackson, a photographer of Oldham. These pictures showed boys occupied in playing various games which had become obsolete. The pictures, which were awarded a medal at Liverpool, were excellent. Mr. Drage also showed some silver prints "made in Japan." The photographs were 10×8 size, printed on albumen paper, and were sold at 4*d*. each. Coloured, the price was raised to 6*d*.

Mr. WELFORD then read a paper on

THE MANAGEMENT OF PHOTOGRAPHIC SOCIETIES.

He said that he did not profess the intention of teaching hon. secretaries their work—the majority of them knew it already. He queried the advisability of meetings in the summer months, stating that the tendency of poorly attended meetings was to become more or less contentious. In many societies it was the impression that, when officers had been elected, the work of the Society for the year was done. He thought, however, that it was the duty of the members to do the work, and of the officers to make necessary arrangements. In other words, the members of the Society should by their enthusiasm carry it on. Membership of a society should involve giving something to the society as well as receiving something from it. When the members were apathetic, the officers were compelled to become too energetic. This might result in their becoming officious. Another difficulty which met every society was the need of good papers. There should not be too much technique, and even a little humour at times was acceptable. It was as necessary that the papers should be well delivered as that they should be good. He advocated the adoption of a series of evenings for "beginners," and severely jumped upon Mr. "Know-it-all," who sometimes damped the ardour and energy of the younger members. With regard to the election of a Chairman, Mr. Welford asked if it is wise to have a different Chairman every meeting. He stated as a fact that he knew of much trouble caused by the changing system, and he suggested electing a suitable man to the post for a year. He was in favour of the formal discussions of papers. Very often the best points were drawn out either in the discussion or in the author's reply. One of the best ideas he had met with (he thought it was due to Mr. Haddon) was the suggestion that members should place upon the notice board the subjects of papers upon which they were desirous of information. Mr. Welford thought that regular excursions were a mistake, and that photographic "outings" should partake more largely of a social character than was often the case. Referring to formal business, he alluded to the divergences in practice which obtained. At some societies the most elaborates minutes were read, whilst at others the press report was snipped from the weekly paper and pasted in the minute book. Mr. Welford concluded with a general statement that the officials did not "make" the society, but that a successful society depends upon the energy of the members themselves.

Mr. BRIDGE said that the question of whether the Photographic Club should meet in the summer time was one entirely for the members. The Club had always met week in and week out from its formation. If any alteration were desired, the rules could be altered. Upon the question of members working and the delivery of papers, Mr. Bridge was quite in accord with the reader of the paper. He had had some experience as Secretary of several societies, and, if the members would only be induced to come forward with papers, the work of the officials would be considerably lightened. As far as a Beginners' Night was concerned, that was a question which was in the hands of the members themselves. As regards the change of Chairman, there were several sorts of Chairmen, the man who knew his work and did it, the man who did not know his work but did not mind being told by the Secretary, and the man who did not know and would not be told. The custom of the Photographic Club had been to elect a Chairman week by week. He thought Mr. Welford's suggestion of a series of Lantern Nights to be called "My Holiday Trip" a good one. It only wanted carrying out.

Mr. SLATER, a visitor from the South London Photographic Society, agreed generally with the paper. As regards the excursions, to be successful these must be continuous. His Society, in which the excursion department was well supported by the members, had a separate Excursion Secretary, and this arrangement was found to work satisfactorily.

Mr. DRAGE, who had had considerable experience in society management, said that he did not approve any system of "worrying" the members for papers. As far as the excursion question was concerned, the essential requirement was first-class management. He did not understand that Mr. Welford, in his paper, referred altogether to the Photographic Club.

Mr. WILKES, who is a member of the Birmingham Photographic Society as well as of the Photographic Club, said that at Birmingham they had a President and four Vice-Presidents. The Hon. Secretary arranged with the latter in rotation to occupy the chair at the various meetings of the Society, and this method was found to work satisfactorily. The Birmingham Society also has an Excursion Secretary, and the excursions formed a strong portion of the programme, and were a successful feature.

Mr. FRY said that he did not agree with many of the suggestions which Mr. Welford had made so far as their possible application to the Photographic Club was concerned. The Club was a mature one, and they had not appealed strongly to the tyro, or to the man who thought he had a passing fancy to take up photography. Looking through the list of members, he would say that, roughly speaking, they had no beginners as members. The Club had to consider what was the average type of its members, and to pursue that course which was most acceptable to the majority. As far as excursions were concerned, he looked upon them as being dead. The fact was, the majority of the members did not appear to want to go an outing. Doubtless a good Chairman was an especial advantage, but he had never observed that the Club had any difficulty in getting a Chairman, or that their Chairmen were inefficient. As far as papers were concerned, he said that the Photographic Club had had some of their very best papers and meetings during last session. They had decided on subjects of interest which had attracted on several occasions a room full of members and friends. The Club had always extended a hearty welcome to non-members.

Mr. BEDDING said that the discussion had drifted from the general to the particular—to the management of the Photographic Club itself. As regard the excursions, he thought that the members were not so enthusiastic about outdoor work as they were. A more vital reason was that the members of the Club were drawn from all parts of London, and consequently an excursion in any direction would possibly be inconvenient to a considerable number. The Photographic Club is a cosmopolitan one, and its circumstances are different from those which obtain in a local organization. He looked upon the Beginners' Night as foredoomed to failure. Being in the chair himself that evening, he agreed with what had been said upon the subject of the Club Chairmen. He would like to see the Club stop their summer meetings. His impression of them was that they were not successful. Learned societies had a vacation, and the one with which the members were most closely connected, the Royal Photographic Society, closed its doors from June to September. He believed that the rest added zest to the meetings when they were resumed, and he pointed out that there was an opportunity at the forthcoming annual meeting for Mr. Welford to introduce any of the reforms which he thought would be of benefit to the Club.

Mr. WELFORD, in his reply, stated that his paper was not intended to be specially applicable to the Photographic Club. It was intended to be of general application. The idea underlying his remarks was that a society should live by the energy of the members rather than by the energy of its officials. He was surprised at the conservative nature of Mr. Fry's remarks, but he noted with special pleasure Mr. Bedding's reference to the vacation.

Mr. BRIDGE proposed a vote of thanks to Mr. Welford for his paper, and added that they were not too conservative to try any good suggestions. The resolution was carried.

Croydon Camera Club.—On Saturday, the 29th ult., a party of members of the Croydon Camera Club, led by Mr. Rogers, had a most enjoyable outing to Greenwich College. The journey was made by boat from London Bridge, and the many interesting subjects *en route* afforded ample opportunities for hand camera workers, which those present did not fail to avail themselves of, and many "snaps" were made. We think there must be a vast field for this kind of work on the river Thames, and wonder we have not more trips by water to record. Arriving at Greenwich pier, the party were met at the College gates by Mr. Haddon and Mr. Collins, who very kindly conducted them round and pointed out the many beauties of this grand institution. Mr. Haddon, the Physical Demonstrator to the College, takes a keen interest in photography, and is well known for the valuable papers he has contributed on the subject, one of his most recent ones being that read at the Convention meeting on *The Washing of Photographic Prints*, and under his guidance many fine views were pointed out of the various parts of the building, and the time was all too short to allow of everything being done; but the party were by no means idle, for about 150 exposures were made, and at the finish a stereoscopic group was taken on the steps under the pediment illustrating "Nelson's fifty battles," the exposure being made by Mr. Collins. After this, Mr. Haddon very kindly showed the party through the suite of physical laboratories, workshops, casting and engine-rooms, &c., and explained the principles of some of

the numberless pieces of costly and elaborate apparatus used in physical research, amongst which, and particularly interesting to photographers, was a fine induction coil used in conjunction with a Crookes' tube for experiments in radiography, together with Spregnel and Giessler air pumps for exhausting vacuum tubes, one of which was connected with the pump, and the various luminous effects produced by passing a succession of sparks from the coil through the tube during the progress of the exhaustion was intently watched and much appreciated by the party. There is a complete plant for generating and storing electricity for lighting and experimental purposes, comprising dynamos of various types, accumulators, primary batteries, Wimshurst and Holtz machines, apparatus for correcting binnacle errors, acoustic, pneumatic, optical, and general scientific instruments *ad infinitum*. Mr. Haddon very patiently and pleasantly replied to the many queries addressed to him as to the uses of the different instruments, and there is no doubt that many returned home with other than photographic "wrinkles" added to their store of knowledge. After leaving the College, the party partook of a typical Greenwich tea, which was done ample justice to, and the return home by tram and train brought to an end a most successful excursion.

North Middlesex Photographic Society.—September 4, Mr. Golding in the chair.—Mr. Gosling showed some prints on Venus paper, which had been distributed at a previous meeting. A discussion took place on the most suitable paper for sensitising, and Creswick drawing paper was well spoken of. Messrs. Golding & Goodwin showed some fine examples of pinhole photography, and Mr. Child Bayley also brought up some negatives and prints therefrom, also taken by means of a pinhole. In the competition for prints taken at the Cambridge and Lowestoft outings, which were merged into one, Mr. Mummery took first place with a photograph taken at Lowestoft, and Mr. Smith second with one at Cambridge. A vote of thanks to Mr. Golding as Chairman concluded the meeting.

Aintree Photographic Society.—September 4.—The chief item was *Platinotype*, by Mr. GEORGE ASHLEY, and this was ably demonstrated. This Society's third Annual Exhibition is fixed for the first week in December. Particulars of open competitions may be had from the Exhibition Secretary, E. P. Heron, 1, Tilney-street, Aintree.

Leeds Photographic Society.—The opening lecture of this Society was given in their rooms at the Mechanics' Institute on Thursday, the 3rd inst. (Mr. Godfrey Bingley in the chair), when Dr. J. T. THRESH took for his subject—

THE PHYSICAL AND CHEMICAL PROPERTIES OF THE NEW GAS, ACETYLENE.

After describing the combination of calcium with carbon in a synthetical manner, he drew attention to the fact that, though acetylene was produced from inorganic bodies, yet an organic body was thus formed from which all other hydro-carbons can be built up for illuminating purposes, and that it is really converted into other bodies, from which thousands of most valuable derivatives may be obtained, stating that all these important bodies, which have been hitherto obtained from coal gas, may now be made from acetylene. He then described how Mr. J. L Wilson, an American chemist, first produced it in the electric furnace by accident, a process by which its price is so lowered as to make it of commercial value. Next he gave the quantities required to make the calcic carbide, its physical properties, the amount of gas it will yield, together with its cost, demonstrating the manufacture of the gas by the addition of water, and showed his audience that it was a colourless gas, and made itself apparent to the olfactory nerves, had an exceedingly bad smell, considerably worse than that of garlic. Its solubility in various solutions was also mentioned, its explosive properties with the atmosphere were also demonstrated, and the dangers of such mixtures were fully pressed upon the audience, he himself having had a very narrow escape from an accident whilst experimenting with the gas. Attention was then drawn to other peculiarities, viz., its illuminating power compared with other hydro-carbons, especially Leeds gas, the condensation to a liquid at about twenty-one atmospheres, and the probability of its being solidified, its portability and method of distribution, its manufacture on a small scale, and its danger of combining with certain metals, forming fulminates, its uses in the enrichment of other gases, and the small percentage of obnoxious compounds formed by combustion. The lecturer then drew the attention of the members to its application to photography, making it useful to the Society, particularly mentioning the superiority of the light for home portraiture, giving details as to how the light should be placed and used to obtain results little inferior to those obtained in a well-appointed studio by sunlight. Enlarging and reducing were well described within the limits of this gas, and too much could not be said in its favour for micro-photography. Its use in the lantern for projection purposes, the arrangement of burners, the amount of light they will give, the size of the screen they will illuminate, together with its simplicity of management as compared with the oxyhydrogen light, render it most invaluable to the lanternist for small audiences. A hearty vote of thanks, proposed by Mr. J. W. Addyman and seconded by Mr. G. H. Rodwell, brought the meeting to a close. It was announced that Messrs. Richard M. Somers and Lionel H. Teale had been elected members of the Society.

Sheffield Photographic Society.—The monthly meeting was held in the Society's Room, Masonic Hall, on Tuesday evening (the 1st inst). In the absence of the President, the chair was occupied by Mr. G. H. Day. After the transaction of ordinary business a demonstration, *Enlarging on Bromide Paper*, was given by Mr. G. TOMLINSON. The manipulation of this paper was carefully explained, the methods adopted for vignetting and printing in clouds from separate negatives shown, and exposure was then made on a piece of 12×10 paper and developed, the negative used being half-plate and the illuminant incandescent gas. Mr. TOMLINSON exhibited a number of prints made by him, and they were much admired. A hearty vote of thanks to the demonstrator brought a profitable evening to a close.

1896. FORTHCOMING EXHIBITIONS.

Sept. 24-Nov. 7 ..... Photographic Salon, Dudley Gallery, Piccadilly. Alfred Maskell, Dudley Gallery, Piccadilly.

Sept. 28, 29 ..... Lewisham Camera Club. H. M. C. Sprunt, 192, New Cross-road, London, S.E.

Correspondence.

☛ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

REMEDIES FOR HALATION.

To the EDITORS.

GENTLEMEN,—I am, as you may know, much interested in anti-halation, and seeing some remarks in your issue of to-day, "Ex Cathedrâ," on the subject, allow me to say I think them somewhat premature. The discovery may be original and effective, and I anxiously await the publication. When visiting Mr. J. E. Bruton, of Douglas, Isle of Man, the other day, he called my attention to the circular. I immediately explained, in confidence, a method I thought out some time ago which savours very much of it. As far as I know, mine is original.

As there are several kinds of halation, I cannot conceive any one method that will meet the difficulties; but a combination will be advantageous. I trust that the method mentioned in the circular will throw some light on the subject. I am never behind in paying for information, should it be original.—I am, yours, &c., A. L. HENDERSON.

277, *Lewisham High-road, S.E., September* 4, 1896.

To the EDITORS.

GENTLEMEN,—In your issue of September 4 you have two paragraphs referring to a circular which I considered ought to be in the hands of every photographer.

The plan or method (not backing) came about in this way. I had been trying for many days to get a photograph of the interior of a chapel, the east window of which has a considerable amount of transparent glass. The result was very unsatisfactory.

My assistant, who is of a practical turn of mind, suggested an idea, and I at once was so pleased with it that I immediately adopted it, being most anxious to get the best effect, the result of which you will see from the two photographs sent per this post.

The method is so simple that the most inexperienced could use it.

My assistant suggested, after we found the result so gratifying, that we should keep it to ourselves, but I thought otherwise, as I had derived so much advantage from it. So we mutually issued the circular referred to as a means of aiding other photographers to benefit by it at a small cost. I would gladly have given a five-pound note for it.

I am pleased that Mr. A. Freke has been the means of bringing the subject so prominently before the photographic world by the aid of your valuable JOURNAL.

Thanking you in anticipation for the insertion of this letter,—I am, yours, &c., GEO. A. DEAN, *Photographer (late of the Isle of Man)*.

14, *High-street, Rugby, September* 8, 1896.

[The non-halated picture, compared with the other, is very good, but not better than similar results we have seen produced by backing the plate, or reducing the halated parts of the negative.—EDS.]

PHOTOGRAPHIC RESEARCH.

To the EDITORS.

GENTLEMEN,—I noticed recently that, in an address at one of the Society meetings, you spoke of more definite and organized research being needed, and giving an idea of how it might be accomplished.

I agree with you that far more might be quickly done, and, seeing that 999 out of 1000 photographers do not care anything whatever about the why and wherefore of results, it must rest almost entirely with the journals to foster, perhaps organize, such investigations.

Photographic science is, doubtless, in its infancy, and at present under a cloud, so that progress is very slow.

I suppose the present is a stage through which all sciences pass, but when you carry your ideas a little into practice I shall be glad to know, and, if possible, do my part.

At present the whole subject seems to be left in the hands of those who desire to make a name for themselves.—I am, yours, &c.,

JOHN STERRY.

3, *Prince's terrace, Cavendish-road, Felixstowe, September* 2, 1896.

ABOLISH THE PATENT LAWS.

To the EDITORS.

GENTLEMEN,—The readers of technical journals and the newspapers are quite surfeited by notices of real or imaginary histories of inventions and discoveries, each setting up a claim, for himself, or somebody else, as the first inventor. Now, I respectfully submit, that the time has come, owing to the existence of a higher intelligence, and the extension of technical knowledge, to consider the question whether it is possible for a *single person* to be of himself a true and *only* discoverer of a novelty. Progress depends not for its success upon any single individual effort. The laws of nature are not partial, they are within the grasp of all, and no man has any right to place a barbed wire fence around any particular application of laws that were created for the universal convenience of all. It has been demonstrated, over and over again, that similar ideas occupy the minds of persons resident on both sides of the globe simultaneously. Inventors are continually at loggerheads at the Patent Office, and soon the nuisance will become, if not already, intolerable.

I am reminded to write upon this subject by reading an imaginary story of the "discovery of zinc etching and photo-lithography" in this week's JOURNAL.

It matters little to myself, and less to the public, I suppose, when I affirm that the story is not according to fact in any particular. Zinc etching was a commercial article long before Sir Henry James reached the Southampton ordnance establishment, and photo-lithography was in active operation in Messrs. Nelson's, Edinburgh, before it was started at Southampton. I have read this story before, in print, years ago; it is absolute nonsense, and, if Sir Henry was alive, he would join with me in disclaiming it. I have had the pleasure of the Colonel's acquaintance at Southampton, and during prolonged interviews Sir Henry never laid claim individually to either zinc etching or photo-lithography as being the inventor. His whole boast was "that he had a *staff of experts* who could accomplish anything;" and, after personally inspecting the extensive works, I considered him fully justified in his assertion, for in all my long life experience of over fifty years, actively engaged in *printing-ink photography* and lithography, here and in America, I never met a better or higher class of workmen than those at Southampton at that time (1867).

But I am digressing from my subject. I believe I am not alone when I say the patent laws should be utterly abolished, on the same lines as has been done with all taxes upon knowledge and postal intercourse, which now has full swing in the penny stamp. The patent law is a huge injustice to the inventor himself, and in practice it is simply the law of the "squatter," and an obstruction to the universal welfare of the world's progress. The Government fees and the grasping of the moneyed speculator leave the inventor the bare bare bone to subsist on. Who can deny it?

Why should these "brakes" to the wheels of progress be applied at all? The powers of invention are crippled and handicapped by patentees who have extracted the germ of their invention from the brains of others. The protection given to inventors belongs to a very primitive state of society, the day of its usefulness has passed, and the world's progress demands that all hindrances placed against its forward march must be cleared away, that the intellects of the whole world may have free scope to exercise and reap the profits to the full of their fertile minds and deft hands, without Government interference or the nefarious huckstering of capitalists in search of food to sustain their "horse-leech" appetites.

I conclude by stating that two gentlemen inventors of the United States are, between them, credited with obtaining no less than a thousand patents! JOSEPH LEWIS.

Dublin.

THE UNFORTUNATE CHEMIST.

To the EDITORS.

GENTLEMEN,—This is the silly season when the big gooseberry rears his hairy head, and the sea serpent winks the other eye, and newspaper correspondents and penny-a-liners nibble their pens and twiddle their thumbs for lack of copy.

But, bless me! what a godsend it is that there is one time during the year, when we can grind out twaddle—and get it printed too—and generally write without rhyme or reason and not be accounted fit inmates for a lunatic asylum.

Here is "Dogberry," banging his head on the good old substantial pharmaceutical rocks and evidently getting well bruised in the bargain, as shown by his inability to write logically and fairly. He has donned the spectacles of prejudice and passion, and selects an eminent Edinburgh firm and contrasts them with "a little country chemist with shop floor and linseed oil antecedents."

We have a term here in Lancashire which fitly expresses the conduct of any person who adopts extremes. He is either staring or stark mad, they say.

But I have yet to learn that it is not wise to begin on the lowest rung of the ladder, and surely the knowledge of the handling of a broom is no disqualification for the selling of a pound of hypo. I myself have commenced the day in the manner "Dogberry" describes, sold a pint of that "bête noir" of his, proceeded to make an analysis of urine for a member of the medical fraternity, effected the sale of a Wray's lens, and extracted a couple of teeth, and yet I am able to understand "Dogberry's" gush.

The height of absurdity is reached, though, when an attempt to describe the subjects of the chemists "exam." is made. Sufficient *quasi* botany and materia medica he says, and then stops. What about the other subjects, friend "Dogberry?" Is our knowledge of them thorough, or *quasi*, or none at all? or are there any more subjects? I advise your able correspondent to rub his nose over the pharmaceutical curriculum before he writes again to amuse your readers.

Really these two champions of the photographic dealer must be more careful. "Cosmos" rants off a length one week about the chemists mercilessly cutting prices, and then "Dogberry" steps in with his little lot to the effect that he has been ridiculously overcharged.

Gentlemen, if you wish to make any impression on the pharmaceutical citadel, be sure you have got the right weapons, learn how to use them, and do not mix your ammunition. When two horses are employed, it is usual for them to pull in the same direction; if they are yoked at opposite ends of the coach, very little is accomplished, and the driver looks foolish.

But it is the silly season.—I am, yours, &c., WILLIAM HAMPSON.

Leigh, September 5, 1896.

"PHOTOGAROMS."

To the EDITORS.

GENTLEMEN,—For a kind of coloured pictures, exhibited in various windows, the above expression is used. Will you kindly explain in what manner they are obtained?—I am, yours, &c., H. BRAESS.

Liverpool, September 1, 1896.

[Our correspondent probably means "photo-chroms." These pictures are produced by a secret process, which is probably a combination of photographic and chromo-lithographic printing.—EDS.]

THE PHOTOGRAPHIC SALON.

To the EDITORS.

GENTLEMEN,—Will you allow me to call the attention of your readers to the fourth Exhibition of the Photographic Salon, which will open at the Dudley Gallery, on Thursday, the 24th inst.

May I also remind intending exhibitors that all pictures for exhibition will be received at the Gallery on *Monday, the 14th, only*, between the hours of 11 a.m. and 6 p.m. Entry forms may still be had on application at the Gallery, or by letter.

Messrs. Dicksee of 7, Rider-street, St. James's, S.W., the well-known exhibition agents, will undertake to receive, deliver at Gallery, and return exhibits on very moderate terms.—I am, yours, &c., ALFRED MASKELL,

Photographic Salon, Dudley Gallery, *Hon. Sec.*

Egyptian Hall, Piccadilly, W., Sept. 1, 1896.

LEYTONSTONE CAMERA CLUB EXHIBITION.

To the EDITORS.

GENTLEMEN,—I regret to inform you that, owing to the loss of our studio and club property, we reluctantly feel compelled to announce that our usual Exhibition will not be held this year, but we hope to have a special Exhibition of members' work early in the new year.—I am, yours, &c., B. HARWOOD, *Hon. Secretary.*

110, *Windsor-road, Forest Gate, E., September* 4, 1896.

[We are sorry to learn that the Leytonstone Club's open Exhibition will not be held this year, as the previous displays organized by the Club have invariably been extremely good.—EDS.]

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GARDENWOOD & CO., 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:—

William Harrison, Kewaigue, Braddan, Isle of Man.—*Photograph of storm in Douglas, Isle of Man.*

COLONEL GUBBINS.—Received. A little misplaced ingenuity on the part of the printer.

FERROTYPE PLATES.—BEGINNER. Fallowfield stocks them, and also some ready-sensitised, we believe.

W. L. N. (Northwood).—The idea is to endeavour to make question and answer generally as well as particularly instructive.

"BENNETTO'S COLOUR PHOTOGRAPHY."—Dr. W. H. PLAISTER. Many thanks for your letter, which we must decline to publish. But please interpret our refusal in the most courteous sense.

PRESERVATIVE OF PASTE.—P. F. S. says: "Can you tell me what is the best and cheapest stuff I can add to paste, to prevent it turning sour?"—In reply: The addition of a little glycerine and oil of cloves, at the moment of preparation, will probably answer.

SPOTTING GELATINE PRINTS.—E. BATH. You probably did not match the colour of the print. If this be done, and the water-colour pigment be thinned down with a little gum water, the marks should not easily show. If using oil colour, dilute with methylated alcohol.

VARNISHING NEGATIVES.—Any of the formulæ given in the ALMANAC are suitable for gelatine negatives; but, as you are an amateur and small consumer, you will possibly find it answer your purpose better to buy varnish from any of the dealers than make it yourself. By doing so you will ensure having a suitable article.

COPYRIGHT.—NORTH BRITON. The portrait being taken in the ordinary course of business, you have no copyright in it. The negative is your property, it is true, but you have no right to use it for any purposes, except to the sitter's order. The sitter can, of course, have the prints you have supplied copied or enlarged by any other photographer.

EARLY PHOTOGRAPHY.—G. WAKLEY. From Hunt's *Photography* you will be able to obtain a great deal of information about the early processes of photography and their working details. There are several editions of the work, which has been out of print for many years. Copies may be now and then met with at bookstalls for small sums. An advertisement or two will, no doubt, put you in possession of a copy.

GELATINE.—T. WADE. By continually heating a solution of gelatine, or keeping it heated for a long time, it becomes impoverished, and loses much of its quickly setting properties. A poor quality gelatine suffers much more quickly than does a high quality one in this respect. The solution may, however, become very greatly impaired, but the gelatine may still retain a considerable amount of its adhesive properties.

PORTRAIT GROUP.—P. MOSS. The portrait lens will, unquestionably, be the quickest acting. But, for an outdoor group, you will get on better with the rapid rectilinear, because it will cover the plate better, and with more even illumination. If the former were used, it would have to be stopped down to such an extent, to get all in focus, that it would then be no quicker than the other, while the result would not be so good in the end.

COLLOTYPE.—T. MORRIS. We think you are misinformed. We have never heard of collotype plates, ready prepared for exposure, being kept as stock articles by the photographic dealers in Germany. We know that the glass is stocked with a ground surface and with bevelled edges, and this is the nearest approach to "ready for use" we are aware of. When a collotype plate is prepared, it must be printed within a day or two, as it will not keep.

TAX ON VEHICLE.—A. Z. complains that he is taxed for a light trap that he uses in his business to take him and his apparatus from place to place where he has work to do, and asks if that is according to law, or should he appeal against the impost?—The trap, if used exclusively for business purposes, is exempt from taxation; but, if it is used, even occasionally only, for pleasnre, a drive out on Sundays, for example, then it is liable for the tax.

REMOVING INK STAINS FROM NEGATIVES.—MOROAN says: "I have printed on a negative. Would you kindly inform me what will remove the ink, without destroying the negative, and reduce the density?"—In reply: Try the following plau, which answers for prints. Dissolve one drachm of oxalic acid in an ounce of warm water, and, having wetted the surface of the negative with warm water, apply the solution, and rub gently until the ink disappears. Keep it warm throughout.

RESITTINGS.—HARD TO PLEASE. Either the sitter is very unreasonable or the work must be inferior; otherwise, with six resittings, the customer would be satisfied. We uote on the circular, on the back of which your communication is written, that sittings are given till satisfied. In face of that, the sitter seems within her rights in what she is demanding. Clearly, at your prices, you will be a loser on the transaction, even if the next sitting pleases; but it cannot he helped if your terms are as the circular shows.

DETENTION OF NEOATIVES.—COUNTY PHOTOGRAPHER writes: "More than three months ago I sent half a dozen negatives to a certain enlarger. On receiving half the order I sent another negative for another. I have repeatedly written for them, and cannot get them or my negatives, or even an answer back. Perhaps you or some of your readers could advise me what is my best course to take to recover my negatives."—Communicate with the Superintendent of Police of the locality where the enlarger resides.

COPYRIGHT.—H. P. H. says: "The following is a question I should like to ask you *re* copyright:—We will presume A. and B. have permission to photograph the interior of a building. A. takes a picture, and makes it copyright. Does that prevent B. from taking the same view for sale, or does it only protect copying the actual picture taken by A.?"—In reply: Registration of copyright only protects A.'s actual photograph, and does not prevent B. taking the same view for sale. Any number of photographers may take the same view from exactly the same point, and copyright the photographs.

USE OF DARK ROOM.—C. W. Of course we shall not publish your letter. What have you to complain of? We should say that the professional who told you that you could have the use of a dark room for changing your plates before business hours was very obliging. You cannot expect professional photographers to stop their business for a stranger to use their dark rooms. Business is none too good with them, even were there a combination, as alleged, amongst the photographers of that place, against lending amateurs their dark rooms. What then? Are not their premises their own?

STUDIO AND BUILDING ACT.—W. W. R. We do not know how the by-laws of the authorities in your town stand, but we may say that you would not be permitted to put up such a wooden studio within the authority of the London County Council. The best suggestion we can make is to get out a rough sketch of what you propose, and submit it to the district surveyor to the Council, or any other surveyor in the town, and hear what they have to say about it, before commencing the erection, the more particularly as your neighbours on either side object to anything like a studio being put in the garden.

TELLING THE COLOUR OF AN ORIGINAL FROM THE NEGATIVE.—H. says: "Is it possible for a photographer to tell, by examination of a negative only, what colours the original object possessed? I shall feel greatly favoured if you can give me your reply in the next issue of your valuable paper. Some amateur friends of mine would like to know. Of course, the photographer would not have seen the object photographed."—In reply: An experienced photographer could hazard a tolerably safe guess, we think. Much, however, would depeud on the nature of the original, and whether it had been photographed orthochromatically; but, generally speaking, it is possible for a photographer to do so.

R. H. U. E. says: "I shall be much obliged if you will inform me what is the correct proportion of the two acids, nitric and hydrochloric, to make aqua regia. The acids I use are pure and concentrated, *i.e.*, P. B. strength. Also, what would be the theoretical quantity necessary to just dissolve 100 grains of fine gold? Captain Abney gives the proportion of one pint of nitric, and five pints of hydrochloric, whilst others say one to three."—In reply: I. Proportions of 1:3, 1:4, 1:5 are recommended by various authorities, with a preponderance, we think, in favour of 1:4. 2. The information will probably be found in Storer's *Dictionary of Solubilities* to which we refer you. We have not the precise information handy.

PANORAMIC CAMERAS.—L. JEFFREY says: "I should be very glad if you could give me any particulars of cameras for taking panoramas complete. I have made a camera which works all right, but am informed to-day that there are several others already in existence. I should be very glad if you could tell me how the cameras work, or, better still, give me the numbers of the patents if they are patented, so that I might see clearly from the specifications how the motion is obtained."—In reply: We cannot refer you to individual specifications, but an hour spent at the Patent Office library would put you in possession of the necessary data concerning patents for panoramic cameras that have been taken out in recent years. The article in our 1892 ALMANAC on *Photographic Panoramas and the Means of Making Them* describes several panoramic cameras, and would probably be useful to you.

REMOVING SILVER STAINS FROM NEGATIVES.—SERIOUS says: "Will you kindly inform me how I can take silver stains from negatives? I have often seen used a little hypo (few drops), mixed with a saturated solution of cyanide of potassium. Yet, when I used it, no effect was shown. The stains in question were only on negatives about an hour or less. Sulphocyanide of ammonia and nitric acid were tried, but with the same result. The negatives had been varnished, which was thin; methylated spirit was used to remove the varnish before applying other solutions. Would the methylated spirit affect the stains so as to increase the difficulty of removing them?"—In reply: There are two other methods which might be worth your while to try—1. Rub the stains with a little alcoholic solution of iodine, and then apply a solution of cyanide of potassium; 2. A strong solution of potassium iodide, and apply friction. But we know of no really satisfactory formula, although a solution, sold for the purpose by Messrs. Marion, and that we used some two or three years ago, is about the moet effective.

ENLARGINO WITHOUT THE AID OF A CONDENSER.—W. J. H. writes: "During the coming winter I wish to do some bromide enlargements, and, as I cannot make use of the daylight, I would be glad if you could inform me my best way to do it with the aid of paraffin lamp or lamps. I wish to enlarge from half-plate negatives, and want the illumination to cover the plate from corner to corner as in the case of views. I know it can be done with a large condenser, which means an outlay far exceeding my means. Is it possible to make a condenser with two glasses cemented in a tube and filled with water? I fancy I have heard of a clock-face glass condenser made in this way. Shall esteem it a favour if you will let me know through your paper my best way to proceed in the simplest, most economical, and practical method to this end."—In reply: I. A large condenser may be improvised in the following manner:—To a concave glass of about thirteen inches diameter cement a sheet of glass to fit it, leave a small opening, and fill in with pure glycerine. 2. As economy is your chief aim, you may dispense with a condenser in either of the following ways: (*a*) Construct a square box with an opening at the top for a metal chimney. Place a powerful lamp inside, and fit the box close up to the back of the camera which holds the negative. (*b*) Arrange a large sheet of white cardboard as a concave radiator, and place a lamp each side of the concave surface. This will transmit a great volume of light through the negative. This method is a perfectly practicable one, as we know by experience, and is extremely cheap to improvise. Doubtless, from the rough idea here given, you will be able to work out the system for yourself.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1898. Vol. XLIII.—SEPTEMBER 18, 1896.

Contents.

OUR FORTHCOMING ALMANAC.

The time of year has arrived when it is necessary for us to take in hand the preparation of The British Journal Photographic Almanac for 1897. A feature of the volume for the past thirty years has been the co-operation of numerous friends and readers of the Journal, and the Editor takes the opportunity to express the hope that the support so kindly placed at the disposal of his predecessors may be continued to him.

We especially invite contributions on topics of practical interest, and should feel obliged if the articles and any accompanying sketches are sent to us at the earliest possible date.

Secretaries of Societies, and especially of those established since the appearance of the last Almanac, will oblige us by forwarding lists of officers and other details for inclusion in the Directory of Photographic Societies, in order that the list may be made as complete as possible.

The Publishers wish us to remind intending advertisers that the announcement pages of the Almanac are already filling rapidly, and that, to ensure insertion and good positions, orders and copy should reach them without delay.

EX CATHEDRÂ.

Mr. J. E. Shaw, the well-known Huddersfield photographer, is the latest contributor to the "coupon" literature with which we have been enabled, for some weeks, to edify our readers. Mr. Shaw forwards us copies of the correspondence between himself and the firm of diarists. He very naturally takes the same line as the other photographers who have addressed us on the subject, and who have been properly concerned to know wherein the advantage will lie of being advertised to take photographs for nothing. Parts of the replies of the firm of diarists to Mr. Shaw are worth quoting. "Advertising the taking of photographs for nothing," they say, "is no different to advertising that you will send a sample of cocoa, pills, or soap, &c., free, and that is the way fortunes are made!"

* * *

The following, we suppose, is intended to touch the national pride of the British photographer, and goad him into making a fortune: "In Paris the best photographers adopt this system" (*i.e.*, take photographs for nothing), "but then the French excel us in advertising, finance, and photography." We require higher authority before accepting such statements. The firm add further that they are "literally inundated with applications from the *very first* (*sic*) photographers throughout Great Britain, and the only difficulty will be to make a selection!" "Evidently you" (Mr. Shaw) "have no enterprise," &c.

* * *

We need make no further extracts from a correspondence which is full of material for amusement; and, in concluding our references to the matter, we do so by reiterating the observation, that the scheme proposed cannot strike any disinterested person as calculated to be profitable or advantageous to photographers. We do not think the profession at large will support movements whereby the public is led to believe that photographers have adopted the system of taking photographs for nothing on the chance of subsequent orders being obtained, and we are decidedly of opinion that those photographers who lend their names to such proceedings deserve the reprobation of their fellow-professionals.

* * *

We gather from the *Camera Club Journal* that the session 1896–97 promises to be very successful as regards the papers and lectures that are to be delivered before the members.

Promises have been obtained from such men as Captain Abney, Dr. Tilden, Mr. Storey, A.R.A., Dr. Lindsay Johnson, Mr. F. E. Ives, Professor Boys, Professor Roberts-Austin, and others, so that a programme of much diversity and value appears probable. The "Whip Fund" of the Club now nearly amounts to the sum asked for by the Committee, viz., 800*l.*, and it appears to be felt that the future of the Club is "not without hope."

* * *

The Annual Meeting of the National Association of Professional Photographers will be held at Anderton's Hotel, Fleet-street, London, E.C., on Monday, September 28. The President (Mr. W. Barry, of Hull) will take the chair at four o'clock. The agenda are as follows: To receive a report from the Secretary; to fix date and place for summer excursion, 1897; to consider a suggestion as to the Association being conducted on social lines. The annual dinner will take place the same evening at seven o'clock; tickets, 3*s.* each, of the Secretary, D. J. O'Neill, 47, Charlotte-road, Birmingham.

* * *

Mr. R. P. Drage, the Honorary Secretary of the Photographic Convention of the United Kingdom, asks us to state that, during the continuance of the Royal Photographic Society's Exhibition, one of the Lantern evenings will be devoted to a display of slides made from negatives taken by members during the Convention week, illustrative of the scenes then visited. It is to be hoped that Conventioners who took photographs at Bolton Abbey, Fountains, and York, will endeavour to make slides from them and help to make an interesting exhibition on the night in question.

THE POISONS ACT.

We have been asked by a correspondent, a dealer, to state what poisons are scheduled by the Poisons Act, which only pharmaceutical chemists, under certain conditions, may sell to the public. The following is the schedule: Part 1. Arsenic and its preparations, prussic acid, cyanide of potassium and all metallic cyanides, strychnine and all poisonous vegetable alkaloids and their salts, aconite and its preparations, emetic tartar, corrosive sublimate, cantharides, savin and its oil, ergot of rye and its preparations. Part 2. Oxalic acid, chloroform, belladonna and its preparations, essential oil of almonds (unless deprived of its prussic acid), opium and all preparations of opium or of poppies.

The Act, in its very first sentence, recites the "safety of the public" as its reason for giving the Pharmaceutical Society control over those who retail or dispense the poisons scheduled, and therefore we must suppose that the Legislature, in its wisdom, backed up by the Pharmaceutical Society, discerns no menace to the safety of the public in the indiscriminate sale of silver nitrate, bichromate of potash, pyrogallol, the caustic alkalies, sugar of lead, and the mineral acids, most of which have on occasion played the dismal *rôle* of abbreviating human life. The Act, therefore, is a failure, and defeats its own object of restricting the sale of "poisons" by a privileged few.

The Poisons Act stands in need of amendment, not only in the respect pointed out, but in that of including others besides pharmaceutical chemists within its scope. It must strike everybody as ridiculous that a photographic dealer may sell one poison with impunity, and run the risk of prosecution for retailing another. It is equally absurd that, if a small quantity of a scheduled poison is wanted for commercial or scientific purposes, some method other than that of compelling the vendor to be a pharmaceutical chemist—for that is what it amounts to—could not be adopted for rendering it available. It appears to us that photographic dealers, and suchlike, might, as in the analogous case of the retailing of the "old" methylated spirit, be granted permission to sell small quantities of the poisons used by photographers, provided a register be kept, signatures be taken, and other safeguards adopted. At any rate, the continuance of the Pharmaceutical Society's system of entrapping offenders for doing with the right hand what they may pass unscathed for if they do it with the left is an outrage on common sense.

We have frequently raised the ire of many of our correspondents and some of our chemical and drug contemporaries by stigmatising the Pharmaceutical Society as a trades union. A copy of the Poisons Act is before us as we write, and the whole tenour of that remarkable statute is unmistakably to invest the profession of pharmacy with a monopoly: that of the sale of poisons. The Society grants certificates of skill, and it prosecutes those who infringe the privileges of its members; allows the widow of a deceased chemist to carry on the business provided she employs one of its members; and it has a benevolent fund for the widows and orphans of deceased members. Apparently it is not only a trades union, but a benefit society. We shall be convinced that the Pharmaceutical Society has the safety of the public at heart when the Act it administers is so amended as to be drawn less in the interests of pharmaceutical chemists and more in that of the public.

Glow-worm Light.—At a recent *séance* of the Paris Academy of Science it was stated that the light emitted by glow-worms was found to be able to penetrate black paper, and affect a dry plate folded in it.

Dangers of Celluloid.—As our readers are well aware, a number of large gooseberry type of paragraphs referring to celluloid explosions went the rounds of the papers some year or two ago, and, as a consequence, a reaction set in; but it must be well borne in mind that there is a real danger in the material under certain circumstances, for, under particular conditions, it is quite capable of becoming powerfully explosive. Further, as a reviewer in *Nature* recently remarked, "celluloid shavings should never be allowed to accumulate, as they take fire easily, at a comparatively low temperature, and in this state burn with surprising rapidity."

The Art Union.—The copyright in the picture, by Mr. E. A. Abbey, A.R.A., *Richard Duke of Gloucester and the Lady Anne*, which was shown at the last Exhibition of the Royal Academy, has been secured by the Art Union of London. The work is to be reproduced as an etching by M. Leopold Flameng, and will be a presentation print. Several of the presentation plates of the Art Union of late years have been etchings. Formerly they were line, mezzotint, or mixed style, but photogravure seems to have sent those styles of work quite out of the field; indeed, there are now no really good workers of the old school of engraving to be obtained now, or, doubtless, the Art Union would avail itself of them. The old hands have died off, and there are no new ones to take their places.

Photographic Apparatus.—In a shop window, not very far from Charing Cross, there is an announcement of a clearance sale of the photographic stock at great reductions. Here are examples. Shilling cameras are quoted at ninepence; two-and-six-

penny ones at two shillings; three-and-sixpenny ones, two and ninepence; and five-and-sixpenny—the most costly, we think—at four and three. Eighteen-penny stands are one and twopence, while shilling dark slides are sacrificed for ninepence each. Who, in face of these prices, can complain of the costliness of photographic apparatus? However, perhaps the expenditure of a shilling or two of a lad's pocket money may hereafter develop the latent talent, now in embryo, of a great photographer. We have known the purchase of "a guinea set" being the means of the evolution of more than one amateur photographer, who has afterwards distinguished himself, though with a superior class of apparatus, it is true; but the cheap outfit must be credited with creating the taste for the art.

Photographing Electric Discharges.—It is reported from Turin that M. Rhigi has been successful in "producing and photographing globular lightning." As the experimentalist is stated to have produced the lightning, we presume this is a laboratory experiment only, yet it may prove that this form of electrical discharge has existence. It has always been a doubtful matter amongst scientists as to whether there are globular forms of lightning. Meteorologists are very anxious to obtain photographs of lightning, and have at times appealed to photographers to secure them for them. Photographs of lightning can only be successfully obtained after dark. Photographers are, as a rule, not sufficiently weatherwise to foretell when a storm at night is to be expected, and the daily forecasts, as issued by the Meteorological Office, such as "possibly thunder," &c., are not sufficiently reliable to induce photographers to keep out of bed on the doubtful chance of the forecast being fulfilled. If the weather forecasts were more trustworthy than they are, they would be a great boon to photographers.

Poisoning by Pyrogallic Acid.—One day last week the Coroner for East Sussex held an inquest on the body of a lady who was accidentally poisoned. It appears that the husband, a doctor and an amateur photographer, had left some chemicals on a sideboard where the lady also kept her medicine, and in the dark she took up the wrong bottle. It contained a solution of pyrogallic acid, some of which she drank. She became ill, and died some days afterwards. It is not stated what was the strength of the solution, or the quantity swallowed. This would have been interesting to know, as this is the first case we remember of fatal poisoning with pyro, although it is known to be a poison. Either a very small quantity was taken, or it must be very slow in its action, for it is stated that the poison was swallowed on the Friday, and death did not result till the Tuesday following. The case should serve as a warning to amateur photographers not to leave their chemicals where they may possibly be mistaken for other things. All developing agents may be classed as poisons, though some are more potent than others.

Fatal Benzole Vapour Explosion.—While some boys, at Hull, one day last week, were playing with some empty benzole drums, one of them exploded, killing one lady, and seriously injuring another who happened to be passing at the time. It is said that one of the lads struck a match and applied it to the drum, when the mixed benzole vapour and air within exploded. Volatile liquids, such as ether, benzole, alcohol, &c., the vapour of which, when mixed with a certain proportion of air from explosive compounds, are not so much used in photography as they were in the collodion days. Still it is well to allude to the danger there is with them under certain conditions. For example, if in a bottle from which methylated spirit has been drained a certain proportion of air is introduced, and allowed to mix with the alcoholic vapour, a highly explosive mixture is formed. We, some years ago, were told by an *employé* at one of the London distilleries of a verdant, young, and over-officious exciseman, who a few days before, would insist upon seeing into an empty spirit cask with a lighted taper. The result surprised him. He was blown some distance, though not seriously hurt; but, as our informant said, he received such a lesson that he was not likely to again pry into empty spirit casks with a lighted taper.

Keeping Power of Plates.—*Apropos* of the keeping power of plates, we have lately met with two very contradictory experiences. Having occasion to wait at a roadside station some little time when on a photographic tour, the station-master entered into conversation with us and a brother artist. He brought out a negative taken on an Ilford plate that was one of their very earliest make, and had been kept two years after exposure before developing, yet the negative was technically perfect, free from spot, stain, or fog—surface or otherwise. The other instance we refer to was just the opposite. The packet of plates had only been opened immediately before use, and had been stored in a cool, dry cupboard, but, when they came to be developed, were almost entirely covered with a dense metallic fog. The angry owner was about to write a scathing letter to the makers, when, just in time to prevent it, he discovered a large hole on the back of his cupboard, which opened directly upon the sink, down which he poured all his waste hypo after precipitating with liver of sulphur! The sulphuretted hydrogen evolved was enough to spoil any plate unless soldered up in a metallic case. The moral is obvious.

Herr Andrée's Balloon.—Some time ago, when the geographical world was in a state of excitement over Herr Andrée's projected balloon trip to the Pole, we detailed some portions of the arrangements, referring to the large number—reckoned by thousands—of dry plates that had been taken aboard. Unfortunately, Fate, as typified by the wind, was not propitious: the balloon did not start, and the plates remain unused. The manufacture and method of packing of these necessary adjuncts to photographic practice has been brought to such a pitch of excellence, that Herr Andrée's store, if kept, should be quite fit for use when he starts next year; but, as a matter of precaution, it would be most desirable that a few packets of plates should be taken at random and tested some little time before he starts, as it would be a thousand pities if, after the daring aeronaut reached his goal and had been able to make a series of exposures, and, further, return in safety with them, he should find them useless. There is every probability that he will start, for the balloon proved to be impervious to the atmosphere after three weeks' exposure in the open air; and all the apparatus for filling, &c., is left intact at Spitzbergen, awaiting his return in July next year, which is the date decided upon.

More Railway Concessions Wanted.—It appears that cyclists are still, as they have been for some time past, agitating for some concessions from the railway companies in the matter of fares, or, rather, charges. When the charges for their travelling are considered, one must at once admit that there are very much better grounds for the concessions asked for than there is for the reduction of fares asked for by photographers, or those already granted to anglers. An ordinary third-class passenger is allowed to take half a hundredweight of luggage, which can be stowed in the luggage van free of charge; but a cyclist, although he has no other luggage, has to pay extra for his cycle, and the tariff for that is, in some instances, nearly as much as, sometimes more than, the fare for himself, yet the cycle may not weigh more than half the weight of other luggage he would be entitled to have conveyed free, and not take up more space. All the cyclist asks is that he or she may take the machines free of charge, as they are entitled to do with other luggage, and not any reduction of fares, such as photographers have asked for and anglers have obtained. By the way, what has been the result of the circulation of the petition forms that were sent to the majority of the photographic societies for signature early in the year, asking the railway companies to make a reduction in the fares to photographers?

Ascertaining the Strength of Coloured Light.—The difficulty of comparing the strength or visual intensity of coloured light as against an ordinary standard candle or amyl-acetate lamp is well known, but Mr. Frank P. Whitman, taking advantage of Professor Rood's investigations on such subjects, has devised an apparatus by which such estimations may be made as correctly as with monochromatic lights of different intensities. Professor Rood

made fifty discs of all gradations from black to white, and, when amalgamating pairs of them in a whirling machine, noticed that, when the two greys were much removed in depth, a sort of flickering was produced, an appearance which became less and less as the greys more nearly approached each other in depth of shade. When a colour was paired with a grey, an almost similar effect was obtained. Mr. Whitman uses a white card with the colour to be tested, and exposes the two in rapid alternation to the experimenter's eye. The cards are illuminated by lights of different intensities at opposite ends of a photometer bar, and, by moving the card supports to and fro till the flicker ceases, it is assumed that their relative luminosities are equal: a simple calculation then suffices to give all the *data* necessary for reference at any future time. It need scarcely be said that coloured lights could be compared equally well.

Points for Discussion in Röntgen Work.—Dr. Macintyre, who has done some remarkable work in photographing the whole of the human body by the Röntgen rays, has an article in last week's *Nature* pregnant with important information and hints. We refer our readers who have taken up the work to the original paper,* contenting ourselves with giving a few extracts. Referring to the large amount of current found necessary, he says: "The question will naturally here suggest itself to those familiar with the subject, Is it necessary to use such currents, or could we not do with less energy by economising the force in the transformers and vacuum tube? The question is a very proper one, as all experimenters know that some tubes will give better results than others with a certain amount of force passed through a particular apparatus."

"It may here be pointed out that, in using fluorescent screens for the deeper structures of the body, barium platino-cyanide in some instances gives a better result, or a darker shadow, than the potassium salt. I am quite aware of the fact that the potassium is more luminous, and it may be that it is a particular construction of the screen, or the particular specimen employed, because samples of these salts vary in their effects. After using a large number of different materials, I, like others, have fallen back upon the potassium or barium salts, but employ both. The barium has the advantage of being a good agent, well suited for hospital purposes, and durable." Further, when using the screen alone, he finds a darkened room much better than any form of cryptoscope.

JOTTINGS.

Newquay, hail, all hail, you fair and brilliant gem of the Cornish coast! The eyes of Europe are upon you, for the discoverer of photography in natural colours, Mr. John Wallace Bennetto, has his abode in your midst. The problem that has defied solution for half a century—that has almost fruitlessly engaged the attention of some of the profoundest men of science the world has seen—that has taken rank in difficulty of attainment with the transmutation of the baser metals into gold—this mighty secret has been discovered by one of your townsmen, who, to all appearances, recks not what the world beyond his own surroundings may say or think of him, and is apparently all unconscious of the fact that, by reason of his achievement, the humble village of Newquay may one day be reverently pointed out as the Nazareth—mayhe the Mecca—of Photographic Science!

The astounding and gratifying result of seven years' patient toil in experimental colour photography has not turned Mr. Bennetto's head, as it would have done those of most men, for, with the indifference that is an unmistakable sign of confidence, he appears to be in no hurry to claim the material rewards of his success. Most of us, I fear, would at once have hastened to London, and laid our results before the Queen, the Royal Society, and the world—having previously taken out provisional protection, by the way. The newspapers would thereupon have boomed us, a syndicate would have been formed, a company floated, and the fortunate discoverer would have netted a handsome pile in no time.

Is it only in such far-off unsophisticated places as Newquay that science is looked upon as its own reward? Mr. Bennetto may be a conspicuous exception to the general rule for Daguerre received a handsome sum from the French Government; Dr. Joly is reputed to have sold his colour-screen process to an American syndicate for 6000*l.*; Lippmann, a year ago, got a money award from a Paris society; and Mr. Fred. Ives, after many years' work with the three-colour process, is, I hope, on the verge of turning it to profitable account; so why should not Mr. Bennetto also, as the sporting men say, "stand in?" However, all this, and more, may follow the public exhibition of Mr. Bennetto's results that is shortly to be given at Newquay. What must it be to be there!

I observe an editorial condemnation of the practice of vending and buying secret photographic processes, which, to say the least of it, is not ill-timed, as the secret process-monger is once more raising his head among us. It was only the other day that a bland and plausible rascal robbed several photographers in the north—fancy, in the "canny" north!—of guineas and half-guineas galore by pretending to sell them a secret mixture, alleged to possess remarkable orthochromatising properties. The thing was an imposture. A more subtle person was one of whom I obtained cognisance some years ago. This knight of industry travelled the country with a developer alleged to have been worked out by a well-known firm, and said by him to have the property of enabling exposures to be very materially shortened. It transpired that he used just an ordinary pyro-soda developer, *plus* a caustic alkali; but, for all that, he managed to ensnare quite a large number of victims. Of secret processes it may generally, but safely, be said that they are either old and well-known ideas, or worthless ones, and photographers can therefore lose nothing by not encouraging the traffic.

The agitation that has been directed against the publishers of an annual volume for inviting photographers to allow their names to be printed as agreeable to take photographs for nothing, or on "spec," as Sam Weller accused Messrs. Dodson & Fogg, the eminent solicitors, of taking up cases, is only what might have been expected. A fitting punishment for those photographers, if any, who are so poor-spirited as to countenance this sort of thing, would be to publish their names as a kind of "black list" for the contemplation and contempt of their brethren. May I suggest that the National Association of Professional Photographers should interest itself in the matter?

The continued anger of the pharmaceutical chemists at my (and others') remarks on the action of the Pharmaceutical Society in prosecuting photographic dealers for "offences" which it was surely never contemplated by Parliament they should be prosecuted for, is the best evidence that the photographic trade has not been justly dealt with. Mr. Pike, in reference to my suggestion that chemists often overstep the mark in prescribing virtually throws the onus for this practice on those who go to chemists for something to cure a cough or cold. This no more legalises the action of the chemists in prescribing than does the act of a photographer in asking a photographic dealer for an ounce of mercuric chloride legalise the complacence of that dealer in acceding to the request. But, if the chemist is permitted to go scot free, why not the photographic dealer? Therein lies the whole point of the matter—what is sauce for the goose is not sauce for the gander. As regards Mr. Hampson's somewhat intemperate outburst of last week, I have only to echo and agree with his remark that "what a godsend it is that there is one time during the year when we can grind out twaddle—and get it printed, too—and generally write without rhyme or reason!" It relieves the liver as much as would a one-shilling-and-three-halfpenny box of pills.

* Vol. liv., No. 1402, p. 451 *et seq.*

I am waiting to hear the annual howl of dissatisfaction arise at the awards of the Judges at the Royal Photographic Society's Exhibition. The outside artist element on this year's jury is stronger than heretofore, so that the chances of some curiosities of judicial opinion are proportionately increased. Not more than a handful of members of the Royal Photographic Society are smitten with the queer desire to have the Exhibition "judged" by a number of R.A.'d and A.R.A.'d gentlemen, who, as a rule, are entirely ignorant of photography and its limitations, and a protest is therefore called for against this same half-dozen members being allowed to annually attract ridicule to the Exhibition. Before me, as I write, is last year's illustrated catalogue, and, as I turn over its pages, I see at least one reproduction, the original of which obtained a medal that only an artist could have awarded, and that set us all wondering and laughing in each other's faces twelve months ago. I hope Messrs. Leader, Storey, and Wyllie will not give us away *this* year, but I am filled with apprehension that they may. COSMOS.

PAINTERS AS JUDGES AT PHOTOGRAPHIC EXHIBITIONS.

THE practice has been in vogue at certain photographic exhibitions of inviting painters to act as Judges in deciding upon the merits of the work sent in, either for the purpose of crowning with honour some selected exhibits or, as is the case at Paris, of acting as a selecting committee.

It is worth while to inquire whether there are, at the present day, any reasonable grounds for a proceeding which, at first sight at least, appears to be a confession of extreme weakness on the part of the professors of the art whose productions the public is invited to admire.

By the term painters is, of course, meant those who are painters only, and who have no pretensions to be photographers, least of all pictorial photographers.

Photography is a comparatively new method of graphic delineation, but it has had time to acquire a status of its own, and it is a humiliating admission to make that it has amongst its leading exponents none, or not sufficient men to decide upon what is and what is not of value in their own art. And, if a knowledge of, and training in, other practical branches be an advantage, does it not possess these also in its ranks, for it is certain that very many of our leading pictorial photographers are, at the same time, very capable painters or draughtsmen? Where, then, is the need of flying for advice to the professors of another system?

To put a similar case, what would be thought of the eminent men at the head of electrical science if they were obliged to call in experts in railway engineering, for example, to decide upon the merits of their own delicate instruments, or if microscopists were asked to adjudicate upon the triumphs of scientific photography?

The complacency with which the system has been accepted is certainly surprising when one considers how terrible a confession of weakness it involves. It would seem at once to dispose of the question (in the minds of those who are responsible for the practice) that there is any art in photography. We would appear to be landed on the horns of a dilemma. To admit that there are no artists amongst the body of photographers capable themselves of judging without assistance the productions of their craft is surely to admit that there can be no art in the productions themselves. On the other hand, if it is not art which is to be judged, why are artist painters called in to adjudicate?

The problem is one which is rendered all the more difficult to solve from the fact that we are in ignorance, or at least in extreme doubt, concerning the principles upon which these painters base their decisions. Are we to understand that they admit the art in photography and, if not, on what other grounds do they claim to be experts? And the question is still further complicated when, in addition, sets of lantern slides are submitted to them for the award of a medal. For art? It is difficult to be serious in applying the term to these very mechanical and easily made transparencies. If, on the other hand, they do not deign to examine carefully these little sets of reproductions, but hand them over to some other section of the organization, one wonders still more what great scientific merit there can be in them to justify, year by year, the bestowal of the medal of a learned society.

An important consideration in the matter is that experience has shown us that painters, with the exception of those who may be termed *converted*, base their judgment of the value of a photograph more upon the suggestive use it may have for them in their own art than upon the artistic qualities which it may itself possess. More than this, they look for excellencies in it which science, and not art, is responsible for; qualities which they themselves would condemn in painting excite in photography their wonder and admiration. This is, of course, all very well, and no one can quarrel with a feeling consistent with a negation of art in photography. But the very fact of their selection as Judges presupposes the opposite opinion. Upon what other grounds is it assumed that, because certain Royal Academicians are painters of some repute, and qualified perhaps, to judge of all schools of painting, they are therefore competent to appraise the merits of the inartistic photograph?

But perhaps the most convincing proof of the worthlessness of the system is to be found in its results, for which we need not go back many years. At Paris, this year, the selecting committee, composed entirely of painters, sculptors, and engravers, passed some seven hundred frames. Of this number, one-third at least, if not one-half, would nowadays be rejected at the Dudley or at Pall Mall, for they do not even stick at huge enlargements with pure white skies. Would the smallest provincial society have been more criminally lenient? And where is the great advantage derived from the counsel of these gentlemen, unless, indeed, our own judgment of an art, in which we are supposed to have had some training and experience, is wrong, and that we ought humbly to admire that which, unaided, we should cast aside with scorn? The extraordinary decisions at recent exhibitions have also, year by year, excited wonder and derision. I think even "Cosmos," of this JOURNAL, will support these sentiments. It could scarcely be expected, however, that, on mixed juries, the photographic section should not, now and again, defer to the predilections of their distinguished colleagues of the Academy. Surely it must have been such sentiments of graceful deference which have allowed the medalling of snap-shots of smoking steamers which the rawest practitioner with a Kodak could easily accomplish, and of other exhibits whose merits as photographs or pictures have been somewhat less than apparent.

Whatever theoretical possibilities, then, may be brought forward in favour of a custom which certainly is inconsistent with dignity, the question may fairly be asked, What practical advantage has in any one case been derived from it? I have already shown in previous communications to the photographic press that the whole system of medals at pictorial exhibitions, and especially at photographic ones, is anomalous. The fact that there is, nowadays, practically no competition, except amongst the second and third rates, is obvious, and is of itself a sufficiently cogent reason against the practice, so far as photographic art is concerned. Speaking more generally, it may be valuable to recall a saying of the late Sir John Millais. He said: "There is no comparison in art. You cannot compare works of art any more than you can compare flowers. You may prefer a rose to a lily, but you do not say one is better than another;" which is, after all, perhaps only an application of the household word which has pronounced comparisons to be odious. ALFRED MASKELL.

ON THINGS IN GENERAL.

THERE is much food for thought when a recent leading article in these pages is read in concert with the article upon the Photographic Copyright Union. It is enough to make any professional photographer's mouth water to read of orders by the thousand, for, so far as I can gather, the "quarter of a dozen" order is more the usual thing, and not good at that, for I am told that, if so large an order is given, it is usually on the "on sale or return" principle. A well-known provincial photographer told me the other day of a series of orders he had received amounting to over a hundred copies of a large group, and, after twelve months waiting to be paid, he had the

bulk returned to him unsold. On referring to the various orders received he found they were so dexterously worded as to afford a fair defence if the case went into court. Moral: If you are lucky enough to get more than a "quarter of a dozen" order, see that "on approval" cannot be read between the lines. But this is rather wandering from copyright questions. There is not a shadow of a doubt that the illustrated papers have killed the trade in celebrities. Any photographers of note whose names were "familiar as household words" a decade ago will repeat the same story, "There is no call for celebrities now." Quite recently I was talking to a dealer who is so situated that he would be naturally applied to by any one desiring to purchase portraits of a certain celebrated popular character. "Look here and look here," he said, taking out of drawer after drawer whole bundles of what were once a saleable type of portrait, "I can't sell one of them. When Americans call and I show them, they at once say, 'Oh, that came out in my paper!'" The reasonable deduction from this is that the papers who have stopped the sale are morally bound to pay for the use of the photographs that help to make their papers pay; and, with the exception of a few black sheep, they will pay not only the trumpery half-guinea, which seems to be such a stumbling-block to so many, but a goodly number of half-guineas if the subject is worth it. They are not all worth it! Hence it would seem to be the natural sequence of events that all photographers should join this Union. If a photograph is worthy of being repeated in the pages of an illustrated paper, it is worth paying half a guinea for. As to the proud privilege of seeing one's name in print and counting it as a good advertisement, well, the man must be very innocent who can attach any value to such an idea. There is a reverse side to this medal. There are so many photographs of the most wretched and inartistic character used (gratis ones by our friends the innocents?), that the whole character of journalistic illustration is being gradually degraded, notwithstanding the high pitch of skill to which process workers have attained.

Speaking of process blocks leads one to recall some of the remarks at a recent meeting of the London and Provincial Photographic Association, when Mr. Beckett is reported as having said that the "blocks were not so much to blame as the printing." He put the whole matter in a nutshell. One cause for the Americans excelling us in this kind of work is the skill with which their printers make the block, the ink, and the printing part and parcel of each other. Take the weekly journals of this country, and what do we see? Good prints from process blocks the exception rather than the rule. There is one paper whose results are nearly always superb; there is another whose blocks have the same imprints, but whose illustrations are beneath criticism; there are all grades between.

A correspondent—"Plates"—writes to the JOURNAL to ask a lot of questions that a little common sense brought into play would have rendered unnecessary. First, he receives some plates damaged, and does not write to the sender about them till several days have elapsed. It is exceedingly improbable that, if the latter would entertain such a claim at all, he would do so if not informed of damage per return. Next, he complains that the railway company will not compensate him, because the box was not marked "Glass." Surely he must see that glass goods need more care than hardware, for example; and if the company be not informed that a parcel contains glass, they will not take special care. When such special care is taken, it is charged for extra. Then, again, there is a further extra charge if the company take the risk; as, if the goods are sent at the reduced rate of "owner's risk," they will not pay for damaged contents, unless there be visible external marks pointing to careless treatment. If "Plates" carries out his threat of fighting out the County Court proceedings, he will gain some experience as to the best mode of dispatching cases of dry plates and the like. The cost to him of obtaining that valuable information will be the County Court fees of himself and the company, solicitors' fees ditto, witnesses' ditto. This expenditure will, no doubt, help to fix these useful pieces of information upon his mind, just as in olden times the boundaries of a parish were fixed on the minds of youngsters by the violent application of a bunch of twigs from a birch tree to his *glutei maxima*—the smart pecuniary and the smart corporal.

I wonder what "Scrutator" had in his mind's eye when he put that question about fallacious papers to the Editor? It is, without doubt, the rule, expressed or implied, that papers, before being read at meetings, should be examined by some one in authority; but it is also without doubt that, if the rule were enforced, a large number of societies in the country would have to close their doors for ever if they shut them against the twaddle-mongers. Besides, if only papers of value were to be read, what would become of the secretaries, what of the photographic journals who print the twaddle?

"Give the man a chance," quotes Mr. H. P. Robinson, after the famous *bon mot* of the Leeds Convention Group. It deserves to be written in letters of gold, for it describes the situation to a nicety. Who is there who has not experienced the misery of group-taking, and has not been inclined to empty the chambers of a six-shooter promiscuously among the witlings who cause the tittering that will not be allayed, or the embryo teachers who call out all sorts of advice from every direction in the group? I am naturally a humane man, but I should most willingly consent for one of the number to be flayed alive as an awful warning.

In a recent leading article a reference was made to the possibility of hypo not being pure, though, of three samples examined, the Editor found an impurity of less than one per cent. That is a good enough record, though it is true that the makers of one well-known brand guarantee that it contains 99·7 per cent. of hypo. Mr. Pringle, being asked by "Alpha" the strength the fixing bath should be made at, gives for P.O.P. one part of hypo in seven or eight of water, and with a fifteen minutes' fixing. There is no doubt that the time given is a safe one, but I think it errs on the side of safety. A print is apparently fixed in less than two minutes, provided a dishful of prints gets well moved to avoid contact. I should think six or seven minutes ample, for over-fixing lessens brilliancy. My custom is to give four for collodio-chloride, and a little more for gelatino-chloride, and not put too many prints together. FREE LANCE.

ORTHOCHROMATIC COLLODION EMULSION.

AN article two or three weeks back, by Mr. A. D. Pretzl, on *Orthochromatic Collodion Emulsion for Process Work*, calls attention to a matter that deserves far more attention than it receives at the hands of photographers generally, even those who are in the habit of using collodion regularly. I allude to the far greater facilities in the direction of colour sensitising that collodion offers as compared with gelatine. I think it was Dr. Vogel who some years ago pointed out how much greater an increase of sensitiveness to yellow was obtainable with stained collodion film than with similarly treated gelatine; and, though the remarks referred, if I remember rightly, to bath plates, in which the dye would, of course, be subjected to the action of a large excess of free silver, still the same advantage is offered in a modified form by stained emulsion containing no such excess.

But in the case of collodion emulsion the advantage to be derived from the practice of colour sensitising is not confined to orthochromatic work, as it is termed, that is, the correct rendering of colour values, but it becomes a direct means of increasing the sensitiveness, at least under some conditions, if not under all. The comparative inferiority of dry-collodion plates when pitted against gelatine or even wet-collodion is due to their relative insensitiveness to the green, yellow, and red rays, and to weak light generally. If, therefore, we can increase the sensitiveness to those rays, without unduly decreasing it to the violet and blue, a distinct advantage must be gained. It was, I think, Mr. J. B. B. Wellington who first utilised this accelerating action in connexion with collodion emulsion, and, though it is now some years since his formula and method were published, very little further advantage has been taken of the principle.

The idea of staining collodion films with a view of rendering them more sensitive to special rays is far from being new, and antedates orthochromatic photography by many years. Carey Lea and others nearly thirty years ago advocated stained films for landscape work, and, though the primary object was rather the prevention of halation, one of the advantages claimed was a better rendering of foliage and coloured objects generally. But, in those early days, the use of stained films was accompanied by a serious loss of general sensitive-

ness and never secured very general adoption, possibly on account of the employment of unsuitable dyes; Carey Lea used litmus, and aurine and chrysoidine were also pressed into service, but none of them seem to be of any value at the present day. On the other hand, with the introduction of eosine into the collodion film by Colonel Waterhouse, the practice of colour sensitising may be said to have taken practical form.

It is generally supposed that in rendering a film orthochromatic, or sensitising, if for any particular set of rays, its general sensitiveness is reduced even without the use of a yellow screen; but, though this may be the case with gelatine, it is certainly not necessarily so with collodion. Indeed, I have carefully compared two samples of the same emulsion, stained and unstained, and even in bright summer light at midday have been unable to detect any difference, at least in the way of falling off, on the part of the stained sample. But, when the same two samples are compared under conditions which bring the colour sensitiveness into action, as for instance on a dull day, or late in the afternoon, a distinct advantage can be claimed for the stained emulsion. Here I am speaking of colour sensitising in its simplest and crudest form, the mere staining of the emulsion by the addition of colouring matter after the sensitive salt has been formed; but, if provision be made for the combination of the dye with the sensitive material, the beneficial effect is correspondingly increased.

This being the case, it would seem to be the proper course for every user of collodion emulsion to resort to colour sensitising, as by that means he directly increases its sensitiveness under those conditions when the increase is most desirable. Thus, in the case of lantern-slide work, most of which, whether by day or artificial light, is done in the winter months, the advantage will be specially noticeable, and exposures, either in the camera or by contact, will be very materially shortened by using stained emulsion, and still more so with one properly orthochromatised. I have heard of collodion emulsion plates being exposed all day in the camera for the production of a lantern slide, and, though the exposure seems inordinately long, I have not the least doubt as to the accuracy of the statement. Yet with an orthochromatic emulsion there is no difficulty in getting a fully exposed slide by reduction, with a minute, or, at most, two minutes', exposure on an ordinary clear winter day. With artificial light the advantage is equally, if not more, marked, and thus, whether by contact or in the camera, the use of stained emulsion is beneficial.

The only question that remains is whether any counterbalancing demerits accompany the increase of sensitiveness. The first point to be examined is the keeping quality of the emulsion when colour-sensitised, and this will naturally vary with the method adopted. It is usually said that orthochromatic plates or films are not to be relied on after a certain age, and, while I am not prepared to agree that this is *necessarily* the case, it is an undoubted fact that some of them are not. This, however, is rather the fault of the method than of the principle. So far as my own experience goes, the simple staining of the emulsion with eosine, erythrosine, and turmeric is absolutely harmless so far as the keeping qualities are concerned, and, though the advantage accruing under such conditions is not great, it is still noticeable. When chlorophyl is employed, I am inclined to think there is a decided element of uncertainty introduced, for I have found such emulsions become decidedly foggy after a time, and, even when that does not occur, the beneficial action of the chlorophyl soon passes away.

When the colouring matter is added to the emulsion in combination with ammonia or other matter tending to help it to combine with the silver bromide, I think there is always a certainty of the ultimate failure of the preparation, unless the emulsion be washed. And there lies the whole secret of success or otherwise on the keeping of orthochromatic films. If the combination takes place directly between the dye and the silver salt, all excess of the former must be rigorously removed, or the ultimate decomposition of the sensitive material is certain. Perhaps where the maximum of effect is derived it is better therefore to treat the films separately, rather than to operate upon the bulk of emulsion.

On the question of whether orthochromatised collodion films are more difficult to handle than ordinary ones, I think it may be said that no trouble will be experienced. Bearing in mind that they are far less sensitive than ordinary gelatine plates, it may be accepted that, with ordinary care, the same treatment that will do for one will do for the other. Of course, if the attempt be made to work colour-sensitive films in a light that will barely be safe with wet collodion, the operator must expect to suffer; but I imagine nowadays most workers are inclined to err on the side of safety, rather than the reverse.

From every point of view I am inclined to think that, for all ordinary winter work, it will be found advantageous to adopt the practice of colour-sensitising collodion emulsions.

W. B. Bolton.

RETAILING POISONS.

Much correspondence has recently taken place as to the unfairness of chemists and druggists having a monopoly of retailing certain dangerous poisons. It seems to me that the case is argued from quite a wrong standpoint. In the first place, why was an Act passed at all securing the monopoly to presumably qualified dealers? It most certainly was not with the idea of giving any *commercial* advantage to the druggist, as the trouble of complying with the Act, and the small money values disposed of by any individual druggist quite negative that idea. It was simply because of the ease with which the public could obtain poisons for nefarious purposes from utterly irresponsible people, and the carelessness with which such dangerous substance were sold and used. Flour, arsenic, whiting, sugar, &c., were frequently sold out of barrels and drawers in the same shop, and placed in close propinquity to each other without any labels or distinguishing mark whatever. A child might go into a shop for a "penn'orth of arsenic for killing mice," and get it as readily as a pound of sugar. Arsenic in agricultural districts is freely used for sheep dips and other purposes, and in many places kept ready in parcels, and then arsenic was little more than a synonym for poison with thousands of people. One confectioner at Bradford put arsenic instead of plaster of Paris into his peppermint lozenges, sold them freely on a market day, and poisoned numbers of people. Then the Legislature stepped in and framed a law to restrict the sale of arsenic and certain other dangerous poisons by only persons presumably better qualified to exercise care in their distribution.

The wisdom of the Act was soon apparent by the great diminution of deaths from poison. One can scarcely take up a daily paper now without reading of deaths by suicide or misadventure by carbolic acid, a poison sold indiscriminately by irresponsible dealers. Why this also was not added to the schedule was *possibly* because of its extended use and value as an antiseptic, the monopoly of which would undoubtedly cause considerable inconvenience, as well as creating pecuniary advantages that would be unfair, which can scarcely be said of the few chemicals used in photography, if the greatest benefit to the greatest number is to be considered. The absurd outcry about the restricted sale of perchloride of mercury and cyanide of potassium makes me wonder how those who make it would protect the public in any other way, as well or better, than by the present arrangement. So far as I can see, the enforcement of the law in the cases that have given rise to the complaining is no reflection whatever on the ability of the vendors, or, I may say, the sufferers; they merely infringed the law and took the consequences. Some of your correspondents take exception to the druggist supplying bicarbonate for carbonate of soda, &c. If they could spend a day or two behind the counter of a chemist and druggist, they would be considerably enlightened on the nomenclature of drugs and chemicals used by the general public.

Edward Dunmore.

EXPERIMENTS WITH DIAPHRAGMS FOR HALF-TONE WORK.

In the face of the great interest which is at present taken in the formation of the dot in half-tone work, the following notes by T. J. Plaeczsk of some experiments undertaken at the suggestion of Dr. Eder, and reported in the current issue of the *Photographische Correspondenz* will throw some light on the subject.

Although the high perfection of half-tone work is usually ascribed to the excellent cross-lined screens which have been placed on the market, of the best quality, still every one who works the half-tone process knows, only too well, what an important part in the preparation of half-tone negatives the size as well as the shape of the diaphragm plays and that only with intelligent use of the same can a good result be hoped for.

Whether the square or the round diaphragm is better can be easily determined.

It is, indeed, possible with diaphragms of correct size to obtain good results with the round as with the square. An easier coalescenee of the dots in the high lights is undoubtedly obtained with the square stop, as the corners of the square dots thus formed produce a quicker closing up of the same.*

The transparent dots in the lights are also, when a square stop is used, much larger without a network being formed in the lights, which can easily be proved by a comparison of figs. 1 and 2.

Fig. 2 shows the formation of the dot with a round stop which is more favourable to the formation of a network.

Fig. 1.

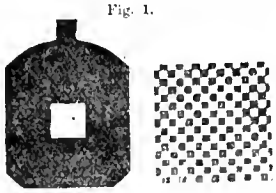

Fig. 2.

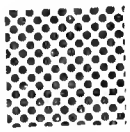

As however larger dots can be sharpened in the lights by longer etching as the result of which the block may be etched deeper, and such blocks also print better, which also speaks favourably for the square stop. Therefore the advantage ought, as a rule, to lie with the square diaphragm. Still better acts the stop when the sides of the square aperture are slightly rounded towards the middle (fig. 3).

If a negative is examined which is made with an exact square stop (fig. 1), it will be found that the transparent dots are almost square; the best form of dot, however, is that in which the transparent dots in the lights approach the circular form, which may be fairly well obtained with the diaphragm (fig. 3).

Fig. 3.

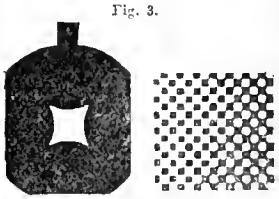

Fig. 4

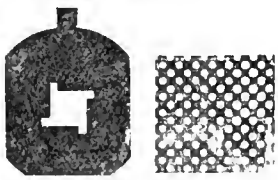

Levy's square stops with cut-out corners (fig. 4) are also very much liked. These also give rounded transparent dots in the lights, without which the formation of a network would easily appear. The points are similar to those produced with stop (fig. 3).

The theory of half-tone work has already been thoroughly investigated by Dr. J. M. Eder, and I shall refer to this. To better understand the following, I will just mention the principal rules of the half-tone process.

As is well known, the screen dot is the product of a pinhole camera, since the transparent openings of the screen act like a series of many pinhole cameras lying close to one another. The formation of the dot on the sensitive plate is dependent, besides the diaphragm aperture, on the distance of the sensitive plate from the screen, on the one hand, and to the optical centre (diaphragm slot of the lens), on the other.

Moreover, to explain these phenomena, let us consider the formation of the dot as normal in fig. 5.

In figs. 5–8, a denotes the diaphragm aperture, b, the aperture of a transparent screen hole, c, the distance of the sensitive plate from the screen; d, the distance of the screen from the optical centre; e, the dot formed on the sensitive plate.

If the distance, c, is increased (fig. 6) the dot e will become larger, which, however, can also be attained by a larger stop (fig. 7), or by a shorter-focus objective (fig. 8).

Small dots are therefore formed if small stops, a shorter screen distance, or a lens with long focus, be used.

The small diaphragms give, as I have mentioned above, small black dots in the negative.

Since the shadows ought only to be formed in the negative by small dots, small stops are only suitable for the shadows, which are well delineated.

In the lights, however, the dots are too small; the same stop which will give good worked-out shadows gives flat lights. There is formed

Fig. 5

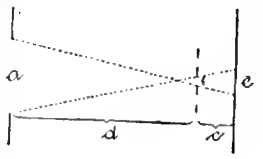

Fig. 6.

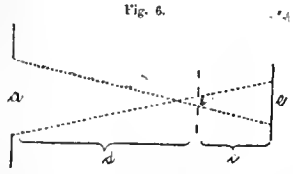

over the whole of the picture a network which makes the negative useless.

As is shown in fig. 7, large stops give larger dots; if therefore one exposes with large stops, the dots in the lights will be good, but in the shadows there will be places free from dots.

Fig. 7.

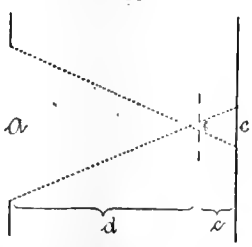

Fig. 8.

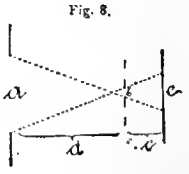

If the exposure be so prolonged that the shadows also showed dots, the lights as a rule would be closed up too much, and the fine dots in the negative in the subsequent transference to metal can only be etched with difficulty, or not at all.

A very small stop is therefore of as little use by itself as a very large one; with medium-sized stops it is possible, with suitable method of working, to obtain useful negatives with one exposure. If an exposure is made first with the small and then with the large stop, the shadows as well as the lights will be well worked through with greater certainty. Since the rapidity of the lens becomes considerably less when using small stops according to the formula $\left(\frac{d}{F}\right)^2 : \left(\frac{d'}{F'}\right)^2$†, it is actually quite logcal that the exposure should be longer, and, as a rule, the small stop requires two-thirds of the whole time of exposure, whilst one-third is devoted to the large stop.

If there are very deep blacks in the original, an exposure should be made with a very small stop on a sheet of white paper, by which means the shadows are cleared up and will not be so clogged in printing.

It might be thought from the above that the half-tones would not be well represented; this, however, is not the case, since the large stops work on the shadows and the small stops on the lights, and therefore by the combination of the two actions the half-tones obtain their full value. It is therefore much easier to attain good results by changing the diaphragm during the exposure than with one stop and one exposure.

In a recent book on the half-tone process‡ formulæ have been recommended for practice which give the correct size of diaphragms. By the aid of these diaphragms with carefully reckoned sizes, a change of diaphragm is almost always unnecessary, since these diaphragms give well-worked-out shadows and lights.§

Although theoretically the fact is perfectly correct, it will be, since the size of the diaphragm has to be reckoned out for every exposure, difficult to carry out in practice on account of want of time.

If the measurements of the transparent places in the screen, the distance of the sensitive plate from the screen as well as from the optical centre of the lens are not accurately carried out, great errors will arise, which will not give the expected results.

* In order to avoid any misunderstanding in interpreting the figures in this article, let me at once state that the whole of the dots correspond to about a sixteen times enlargement of the original screen negatives, so that the black dots of the diagrams correspond to the covered parts of the negatives. The diaphragms given with the enlargements correspond to those with which the dots were obtained, and are about one-fifth their natural size.

† d = diaphragm aperture; F = the focus of lens.

‡ The Halbton process, by Julius Verfasser, translated by Dr. G. Aarland.

§ The size of the diaphragms can be calculated from the formula $a = \frac{c+d.\ b}{e}$ (fig. 5).

With calculations accurately performed, dots in the high lights coalescing, and small dots in the shadows will be obtained.

Even if everything is satisfactory, unfortunately half-tone negatives which have been prepared with one diaphragm give frequently pictures wanting in detail, which are poor in the half-tones, a fact of which I have been convinced for a long time.

If the dots are not satisfactory when a negative is prepared by changing the diaphragm the negative can still be corrected. With these corrections the half-tone negative is very convenient to work with. It is not necessary to take much care of the shadows, but more of the lights and the dots should just touch; still, if the dots in the lights do not quite touch, so that a faint network is noticeable, it is possible to make the dots touch by the lead intensifier, which builds up a dense deposit.

By reduction the dots which are too large in the shadows can be sharpened up without the lights becoming more open.

By various intensifiers it is possible to obtain the lights more open or more closed, as may be desired.

With the mercurial intensifier the dots are least, with the lead intensifier most, spread out. Between the mercury and lead intensifier stands the copper intensifier, with which, as a rule, success will be attained.

The best form of diaphragm is, as mentioned above, the square. The position of the diaphragm opening must be such that the side of the square crosses the diagonal screen lines.

The size of these stops is, for preliminary exposure, from *f*-40 to *f*-50;* for the shadows, *f*-15 to *f*-20: and, for the lights, *f*-12 to *f*-15.

For the large stop, *f*-12 to *f*-15, Levy's stop (fig. 4), or a square stop, which has only two opposite corners cut out, should be used.

If the above fundamental principles are relied upon for practice, it will be easy to immediately obviate any fault that may be formed.

The formation of the dots is easy to regulate. If the requisite care is taken in working, larger or smaller dots may be obtained without trouble, as the original or easy etching may require.

It is interesting that the dots approximately assume the shape of the diaphragms.† With double perforation of the diaphragm, in many cases there is obtained, instead of one point, two.

This process, with irregular or with several apertured diaphragms, Count V. Turati, of Milan, has specially worked out.‡

In the experiments here detailed, a Voigtländer euryscope of 86 cm. focus, and a Levy's cross-lined screen of forty-seven to fifty-four lines to the cm. were used.

The distance of the screen from the sensitive plate was fixed, comprising the thickness of the glass of the screen and the closest possible approach to the sensitive plate.

If diaphragms with triangular apertures in various directions are used (figs. 10 and 11), the dots will also show as small triangles, which are slightly differently arranged, according to the position of the triangle.

Very beautiful results were obtained with diaphragm (fig. 11). There

Fig. 9.

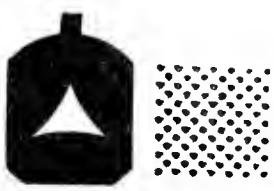

Fig. 10.

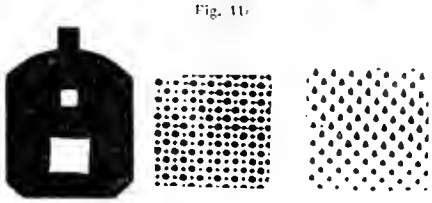
Fig. 11.



were formed between four dots a small dot, which was wanting in the deepest shadows, but appeared in the half-tones and high lights.

The same effect is obtained with this diaphragm as with a screen of double the fineness. The action is exactly similar to Levy's triple-line screen.

* That is to say, the length of the side of the square in proportion to the focus.

† The original form of the dots is considerably altered by intensification or reduction.

‡ Eder's *Jahrbuch*, 1896. *Photographische Mittheilungen*, 1896.

Fine screens cannot be used if, as fig. 11*a* shows, the dot formation is striven for, since these fine dots will not stand etching. On the other

Fig. 12.

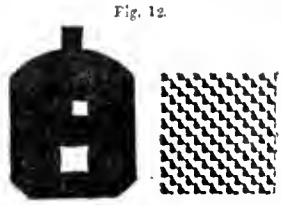


Fig. 13.

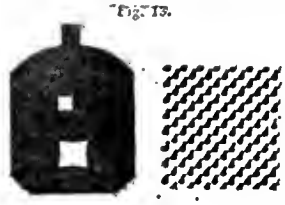

Fig. 14.

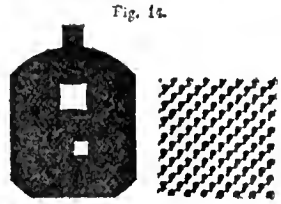

Fig. 15.

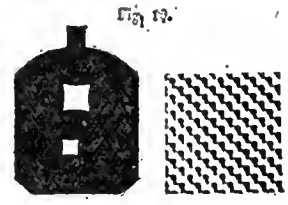

Fig. 16.

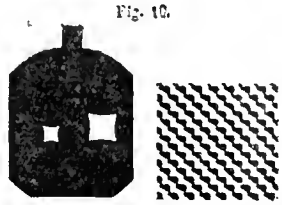

Fig. 17.

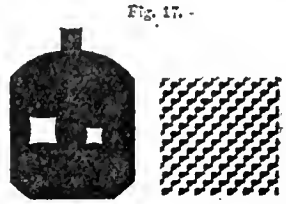

hand, the results obtained with coarse screens are equal to those obtained with fine, and therefore much dearer, screens.

It is, however, not so easy to obtain the small dot (fig. 11*a*) exactly in the middle, and this must be determined by experiment.

Fig. 18.

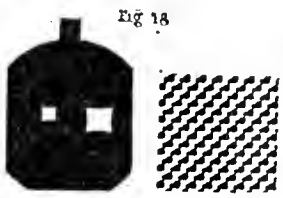

Fig. 19.

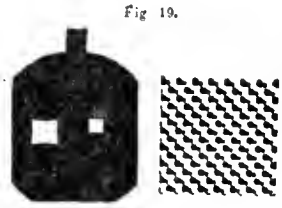

Fig. 20.

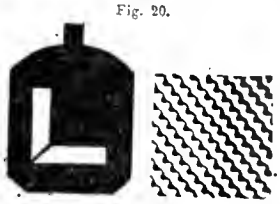

Fig. 21.

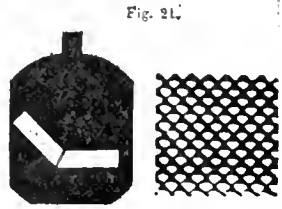

Fig. 22.

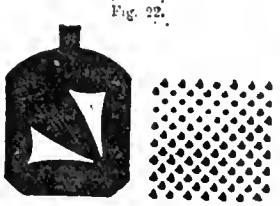

Fig. 23.

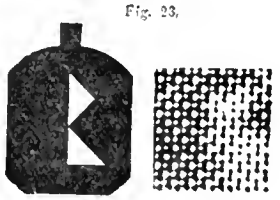

Fig. 24.

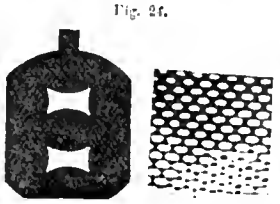

Fig. 25.

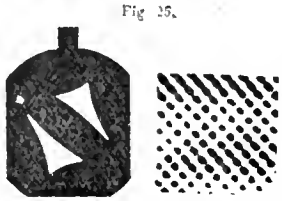


If the distance of the ground glass from the optical centre of the lens is altered, two things may happen: the small dots may move up or

down, coalesce with the large dots, and a pear-shaped dot (fig. 11*b*) is formed, which has its point directed either up or down. This may be also obtained if the centres of the two apertures are approximated or moved further apart.

With double perforated diaphragms, therefore, the dots may be made closer or farther apart, and thus the most different results attained. If the position of the two aperture centres are altered, so that the line which joins them to the centre of the aperture of the screen is made nearer without becoming parallel, various zigzag lines are formed. In figs. 12 to 19 the position of the dots is seen which can be attained by one diaphragm, but in different positions.

Other diaphragms' shapes and their effects in the preparation of half-tone negatives with cross-lined screens are shown in figs. 20 to 25.

As to the practical value of such diaphragms, I believe that they are, with the exception of fig. 11, of little importance for ordinary monochrome printing, but for half-tone three-colour printing they can be of great use, since, *without altering the position of the screen or the original, by simply changing the diaphragm shape, the position and the shape of the dot can be altered for any colour.*

How easily the position of the dots may be changed by the diaphragm is shown in figs. 12 to 19. If one considers that by other diaphragm apertures other dots may also be formed, it will be easily grasped how useful these diaphragms may be for colour printing.

To the double perforated diaphragms belong, therefore, a complete knowledge of the theory of half-tone work, how, with safety and certainty, to obtain, with any enlargement, a reduction of the previously described shapes of dots.

If time and opportunity permit, further experiments will be instituted to study the use of stops for colour printing, and the best form of dots for the same.

ACETYLENE GAS.

[London and Provincial Photographic Association.]

The recent discovery by a Canadian chemist, Thomas Leopard Wilson, of the process for the production, on a commercial scale, of calcium carbide, is perhaps the most valuable of modern times. This substance (CaC_2) is obtained by fusing together, by the aid of the intense heat of the electric furnace, common lime, and any material that will form carbon, such as hard or soft coal, coal dust, or coke. The result of the chemical combination is a mass having the appearance of dark grey sandstone, exceedingly hard, exhibiting a purplish metallic lustre when freshly broken. When this is placed in water, a double decomposition takes place; the oxygen of the water combines with the calcium, forming white lime, which is left as a residue; and the hydrogen of the water combines with the carbon and forms acetylene (C_2H_2).

A few months ago this gas was little more than a chemical curiosity, produced only by costly and elaborate processes; but now, owing to the discovery referred to above, it can be brought into the practical reach of every one, and, by means of a suitable generator, can be used with absolute safety for a variety of purposes. The quantity of acetylene produced from one pound of calcium carbide is about five cubic feet, and, if special burners are used, no more than one cubic foot is required to give a light upwards of sixty candle power for one hour. In colour, the flame from acetylene is beautifully pure white, the spectroscope showing scarcely any difference between it and daylight. On comparing the gas with any illuminant of equal power, it will be found to give out much less heat and to consume a smaller quantity of oxygen in its combustion. Acetylene gas has a strong garlic-like smell, so that a leakage in pipes or fittings would be immediately detected should the gas be adapted for general house lighting.

I have here a generator which, with the valuable aid of my friend, Mr. F. S. Thorn, has been placed upon the market specially for lantern work. Before proceeding to charge and set it in action, I should like to point out that acetylene as generated is hot and extremely moist; and this moisture, held in suspension, must be removed, or it will be deposited in the pipes and fittings leading to the burners, with the result that the light would jump and eventually go out exactly as house gas would under similar circumstances. To prevent this, the gas is first drawn down through the water into a cooling chamber, situated at the bottom of the generator, from which it issues practically dry and ready for use. We will now read the instructions sent out with the apparatus, and proceed to set it in action.

In our first experiments the generator was made of zinc, and for ornament sake the tops were made of copper, both of which materials we have now abandoned, first, because the heat caused by the reaction had a softening and rotting effect upon the zinc; and, second, because acetylene is asserted by several eminent chemists to form an explosive compound with copper, but personally I have not been able to make an explosion, although I have purposely tried to do so. However, we at once decided to discontinue its use, and the generators are now made as far as possible in galvanised iron, and so far this has given every satisfaction. I shall now be pleased to show you the effect of the light in the lantern.

I have here an illustration of a generator we shall shortly place upon the market specially for house lighting and other purposes. This generator is the result of very careful experiments, and is made on an entirely different principle to the one before you, the main features of this generator being that it can be recharged whilst the gas is burning without in any way effecting the light, allowing an escape of gas, or the admission of air to the holder. It will automatically regulate itself to supply gas for any number of burners from one up to the number for which it is built, and will immediately stop generating as soon as the gas ceases to be withdrawn, and any number of lights can be effectually dealt with by means of this apparatus. Here, ladies and gentlemen, are one or two photographs taken by acetylene gas, and also an illustration of the apparatus for taking same. Like the new generator, this apparatus is about to be placed upon the market, and, as I will now show, this small generator will supply it, but, of course, for a short time only, and it is our intention to recommend a larger size. The gas, if burnt with ordinary burners, as used for coal gas, would be yellow, smoky, and quite unsatisfactory, but, if burnt in Bray's 0000 or 00000 burners, a pure white light is obtained of about eighty to sixty candle power respectively; but even these I do not consider perfect, in fact I do not think that a perfect burner for acetylene is obtainable, as there is always a deposit of black carbon on the nipple, which has occasionally to be cleaned off with a penknife, or, better still, a rather hard tooth brush.

Respecting the cost of lighting by acetylene, the 00000 burners mentioned above consume about one cubic foot of gas per hour, and one pound of calcium carbide yields about five cubic feet of gas; so that light for light, compared with coal gas at 2*s.* 6*d.* per 1000 feet, as obtainable in London, the carbide must be purchasable at about 2*d.* per pound.

Acetylene can be compressed; but, as it goes to a liquid at 900 pounds' pressure to the square inch, beyond which it is impossible to compress it, and as it then occupies as much cubic space as it does in the carbide form, and considering the expense of compressing it and the weight and danger of the cylinder, I cannot see the advantage over a good automatic generator, as the first outlay must be as great as the working expense—considerably greater—so that, in my opinion, compressed acetylene will have a very limited use even if introduced.

In conclusion, I think I may safely predict a splendid future for acetylene, and, in my opinion, it will eventually supersede for lighting purposes either oil, gas, or electricity.

C. Hoddle.

PHOTOGRAPHY IN COLOURS AT NEWQUAY.

Mr. J. W. Bennetto, the alleged discoverer of photography in natural colours, writes to our Newquay contemporary as follows:—

"You have taken such considerable interest in my method of reproducing the colours of natural objects by photographic means, that you may be interested in the test, of which I hand you particulars, and to which I have been submitted in order to satisfy those who were reasonably sceptical as to whether, or not, my results were obtained by photography only.

"I hope very shortly to have the pleasure of exhibiting, in Newquay, several pictures produced by the above method, and, doubtless, they will give the same satisfaction and pleasure to Newquay people as they have already given to several distinguished persons who have seen them."

The following particulars of the test referred to are given by our contemporary:—

"Mr. Bennetto being willing to submit himself to a test, the following gentlemen agreed to act as a committee, viz., Mr. C. O. Clark, Mr. J. C. Lomax, and Mr. G. Welman. A colour test had been prepared by Mr. Lomax, who is a well-known artist, in the shape of a rough sketch with bands of various colours at the bottom of the sketch. The dates of the week, month, and year were in different colours. As will be seen from the report, Mr. Bennetto was blindfolded, and did not see the original test till after he had shown his result and it had been carefully examined by the committee. The following is a copy of their report:—

"On Monday, August 31, 1896, Mr. Bennetto was blindfolded, and photographed in our presence a picture which he had not seen.

"The picture was then sealed up, and he did not see it until after he had shown us the result on Thursday, September 3.

"He then showed us a transparency on glass.

"The exposure had been made in perfect ignorance of the subject, and the focus was not correct; under these circumstances we consider that the result represented the colours of the picture sufficiently to prove that Mr. Bennetto can produce colours by photography in a transparency on glass. We are satisfied that the result was obtained *bonâ fide* by photography alone."

The spectacle of Mr. Bennetto, when blindfolded, taking a photograph must have been very strange, and we are not surprised to learn that the "focus was not correct." The qualifications of "the three well-known Newquay gentlemen" to act as referees in so important and abstruse a matter as the verification of results alleged to be photographs in the colours of nature are not stated; but we congratulate them on the very guarded nature of their report. They remark: "*We consider*

that the result represented the colour of the pictures sufficiently to prove that Mr. Bennetto can produce colours by photography in a transparency on glass," which says very little in support of the claims of Mr. Bennetto, who, perhaps, is more easily satisfied than either we or our readers are.

The blindfolding—the necessity for which has not been explained—is a very remarkable feature of the proceedings; and we are certainly of opinion that Mr. Bennetto might choose more scientific methods of establishing his claims. The more he hesitates to exhibit his results and demonstrate his process before those qualified to pass judgment upon it, the longer he deprives himself of the great credit and profit to which, on proof of those claims, he will be unquestionably entitled.

ON THE RÖNTGEN RAYS.*

Now, there is another remarkable property of these rays, or absence of property, if you like so to call it. Rays of light, as we know, admit of diffraction. If you pass light from a luminous point through a very small slit, or a small hole, the riband, or the beam of light on the other side, does not follow merely the geometrical projection of the slit or hole, as seen from the source of light, but is more or less widened, and certain alterations of illumination are visible, a phenomenon referable to interferences, which I have not time to go into. How do these X rays behave under such conditions? It is a very remarkable thing that they do not show these enlargements, or exhibit any sign of interference.

The last number of the *Comptes Rendus* contains a paper by M. Gouy, in continuation of a former paper, but describing experiments carried out in a still more elaborate manner, which proves the truth of this to a very high degree of strictness. He makes out that, if these X rays are periodical, the wave-length cannot well be more than the one-hundredth part of the wave-length of green light, indicating an enormously high degree of frequency.

Now, if we assume that the X rays, like rays of light, and unlike the cathodic rays, are a disturbance propagated in the ether, ponderable matter being concerned only in their origination, not in their propagation, the question arises, What is the relation between the direction of vibration and the direction of propagation? Are the vibrations normal or transversal? We know that the vibrations of the air, which constitute sound, take place in a to-and-fro direction, or what is called normal—that is, perpendicular to the waves of sound. We have the fullest evidence that the vibrations of the ether which constitute light take place in directions perpendicular to that of propagation, or are what is called transversal. To which category do the vibrations belong which constitute the X rays?

If we could obtain polarisation, or even partial polarisation, of the X rays, that would settle the question, and prove that they are due to transversal vibration. But most of those who have attempted to obtain indications of their polarisation have failed. This, however, does not prove that the vibrations are normal, for the peculiar properties of the X rays shut us out—or, at least, almost completely shut us out—from the ordinary means of obtaining polarisation. There is, however, one paper in the *Comptes Rendus*, by Prince Galitzine and M. de Karnojitsky, in which the authors profess to have obtained, by a special method, undoubted indications of polarisation. No reasonable doubt can remain as to the abstract capacity of these rays for polarisation after what has been done by another physicist. I wish I had time to go into the experiments that have been made by M. H. Becquerel in the direction of polarisation; but I have already kept you too long. He had more particularly studied a very remarkable phenomenon, viz., that certain phosphorescent bodies—such as sulphite of calcium, for instance, and salts of uranium—on exposure to ordinary sunlight, give out rays of some kind, which pass through bodies opaque to light, and are able to affect a photographic plate beneath them. So far these agree in their properties with the X rays, which are obtained from a Crookes' tube, which they far more closely resemble than they do rays of ordinary light; but the rays thus obtained were found by Becquerel to admit of polarisation by means of tourmalines in a manner altogether unmistakable. I think, therefore, that we may take it as established that the Röntgen rays are due to some kind of transversal disturbance propagated in the ether.

The non-exhibition of the ordinary phenomena of diffraction and interference is explicable on the supposition that the vibrations in the X rays are of an excessively high order of frequency. I am not sure that a different sort of explanation might not perhaps be possible, which I have in my mind, though I have not matured it; but, save the possibility of that, one is led to regard them as consisting of transverse vibrations of excessively high frequency. This opens out some points of considerable interest in the theory of light, but I am afraid it would keep you too long if I were to attempt to go further into this matter. I will merely remark that, taking the way in which these rays are most commonly produced, viz., as coming from a point where the cathodic discharge in the Crookes' tube falls on the opposite wall, we may understand how it is that vibrations of excessively unusual frequency may be produced. These highly charged molecules, charged with electricity, coming suddenly against the wall, may produce vibrations of a degree of frequency which we are not at all prepared for; but I see by the clock that I must not detain you any longer on speculations. SIR G. G. STOKES, F.R.S.

* Concluded from page 586.

BLACK-SURFACE MARKINGS ON BROMIDE PRINTS.

[Wilson's Photographic Magazine.]

ALMOST every consumer of enamelled bromide paper has now and then been troubled with black markings on the surface of the developed prints. Sometimes these markings are of the character of pencil marks of irregular shape; sometimes they are all turned toward one direction and the lines are parallel to each other. Frequently, too, they affect an irregular shape, as if a finger dipped previously in some dark staining medium had been passed over them. These peculiar markings have puzzled and annoyed photographers who did not know to what cause to ascribe them. They occur most with glossy or enamelled bromide papers, being very seldom found in matt or rough-surface bromide paper. They do not show in undeveloped prints, but are only brought out in development. An immaculate sheet of bromide paper, uniform in coating, with good emulsion and apparently free from defects, may, after coming in contact with the developer, show these various surface markings, especially if the print has been somewhat undertimed, or if development has been forced in order to get the image out. Lack of bromide of potassium in the developer, too strong or too warm developing solutions, are also liable to increase this trouble. Paper which has become very old may have a greater tendency to show surface markings than if it were of more recent manufacture, although very fresh paper may frequently show the same defect. I have become thoroughly convinced that these black surface markings are due simply to pressure or friction on the sensitive bromide film. I am inclined to think, furthermore, that their occurrence may be dependent to a certain degree on electrical conditions. It is a well-known fact that any friction or pressure is liable to develop a change in electrical conditions. I have been able to observe more than once, in very dry weather, that the very fact of pulling the sheet of bromide paper over another or over a table produced electrisation of the paper; this was made apparent by the fact that it was adhered noticeably to the table on which it was handled. When unrolling big rolls of bromide paper the same phenomenon is liable to occur. If my supposition is correct, this would explain why, some days, these surface markings are more liable to be produced than on other days, and why this should occur at unexpected times and on paper of which the emulsion is otherwise absolutely faultless. All of this brings us down to the fact that bromide emulsion paper is an exceedingly delicate chemical article, which has to be handled with the utmost care. Clean white gloves have been used for some time for handling dry plates and bromide paper in the factories where they are made. But this prevents only soiling the surface of the emulsion film by direct contact with the fingers. The very fact that bromide paper has to be wound and unwound, and has to be packed so that each sheet touches the other, affords many opportunities for the production of future surface markings. The dry-plate manufacturer can to a certain extent avoid this trouble by packing the dry plates in such a way as to keep them separated by means of paper strips, thereby preventing the bromide film from touching anything until it is developed.

Notwithstanding all this, many photographers have been bothered with surface markings, affecting the shape of pencil marks, appearing during the development of their negatives. This effect may almost certainly be produced by causing the slide of the plate-holder to rub against the plate. Think what would occur if dry plates (as bromide paper is) had to be wound up and handled several times both by the manufacturer and the consumer, having each time an opportunity of undergoing friction or pressure on the bromide emulsion film!

Many remedies have been suggested for removing from the printed image these troublesome surface markings. One of the oldest and best methods is to clear the markings away by means of a brush dipped in cyanide of potash solution, but this is rather dangerous on account of the poisonous properties of cyanide of potash. They can also be removed by cleaning the dry print by means of a piece of moistened cotton. This goes much easier if the cotton has been dipped in water containing a few drops of ammonia. All the above remedies are liable to injure the film of the image if they are not very carefully used. To my knowledge the very best and quickest way for removing surface markings is to clean the dry finished print with a tuft of cotton dipped in plain wood alcohol. This allows rubbing to such an extent as to remove easily the stains in question without scratching the film. Ordinary alcohol can be used for the same purpose, but it is far more expensive. Those who do not know of this remedy will be surprised when they find out how easily it will enable them to save bromide prints which otherwise would appear entirely worthless. DR. LEO BAEKELAND.

The Inquirer.

*** *In this column we from time to time print questions that may be addressed to individual contributors to our pages, or such as are sent to us with the view of eliciting information from a variety of sources. We invite the co-operation of our readers in rendering this feature of the* JOURNAL *useful and instructive.*

ARON'S ELECTRIC LAMP.—S. M. J. says: "Will some reader oblige me with the address where this lamp, referred to in the SUPPLEMENT to the JOURNAL for September 4, may be purchased."

RETOUCHING MEDIUM.—"Portraitist" writes: "Allow me to thank Mr. Harold Baker and 'Retoucher' for their replies to my query. My object in writing was, if possible to elicit, if not a formula, at least some information as to what constitutes a *reliable* medium, for, as far as my experience goes, those now on the market are as untrustworthy as well can be. I have used them with the finger tip as recommended by Mr. Baker, and with clean rag as 'Retoucher' directs: I have left a lot of the stuff on, and almost none at all, and sometimes get a good surface but cannot rely upon it, which is my cause of complaint. By the way, your printer makes me look rather ridiculous in speaking of 'a solution of common resin or turps.' I wrote '*in* turps.' He also exactly reverses my written meaning with regard to the ALMANAC formula for retouching varnish. I wrote that I wanted '*no* better surface,' not '*a* better.'"

NON-COAGULABLE ALBUMEN.—E. Freeman writes: "Allow me to thank the correspondents who have so kindly answered my query on the subject of non-coagulable, or, as Mr. Banks calls it, 'inverted' albumen. I have tried the method given by that gentleman in the last ALMANAC, but possibly from some fault of my own I have not been able to arrive at a successful result, as the comparatively small proportion of the albumen that separates on the addition of a very large quantity of the alkaline solution slowly but completely dissolves in the subsequent washing. On the contrary, when employing the method given in the leading article of August 15, 1884, in which a very strong solution of caustic potash is used, I have no difficulty in obtaining a product, in much larger quantity, that possesses all the properties ascribed to the inverted albumen by Mr. Banks, and which thoroughly resists the solvent action of cold water. I surmise from this that possibly a mistake may have occurred in the strength of the soda solution given by Mr. Banks, though, I repeat, my failure may be due to my own fault."

TRIPOD STAND "JAMMING."—W. H. Brown says: "In reply to 'Amateur,' I think, if he will try a simple preparation that I have used for similar purposes for some years past, he will find it just what he wants. It was first given in the JOURNAL whence I 'annexed,' it and have since always kept a small quantity in stock for emergencies. It consists of a mixture of wax and French chalk thoroughly incorporated together under heat. If I remember rightly, the original formula gave paraffin wax, which, of course, is the cheaper; but I now use beeswax in preference, as I think it constitutes a better lubricant, though, of course its cost is greater. Melt the wax and stir in the powdered talc until a small portion in cooling is easily friable. This will be found to combine the 'slippery' qualities of the wax, and talc, is as easy of application as soap, and far superior to that substance or either of the ingredients separately, and, while making any sort of sliding woodwork more smoothly, it also protects it from damp and prevents the 'jamming' which is the cause of 'Amateur's' complaint."

RETOUCHING MEDIUM—J. C. says: "Like 'Portraitist,' I too have suffered much from useless retouching media, and would gladly welcome any really reliable plan by which the unvarnished film can be brought to a suitable condition to take the pencil. After intensification with mercury the gelatine film acquires a matt surface, and presents a most beautiful 'tooth' for the pencil, enabling the most delicate work to be done with ease and certainty. But, then, it is not all negatives that are intensified or that will admit of it. There was an article some time ago in the JOURNAL on the subject of giving an artificial 'tooth' to the film by chemical means, but, as far as I remember, no definite process was given. I find that an alumed and perfectly washed film becomes harder and more repellent of the lead, but that, if the alum is only partially washed out, a 'tooth,' sometimes almost amounting to a 'grain,' is given to the film, which causes it to take the pencil readily. But the difficulty is to get the right surface with certainty. Would it be possible, think you, by simply using a solution of alum or other substance of definite strength, soaking the plate, draining and drying without washing, to arrive at a regular and uniform degree of 'roughness?' or is it possible, as I fear it may be, that every plate may require slightly different treatment? Have any of your readers worked in this direction?"

INSENSITIVE COLLODION EMULSION.—I was unable to put the matter referred to by "Halifax"—the coating of unwashed emulsion plates in daylight—to the practical test in time to reply before, but I can now confirm what was said by W. B. B. recently that such exposure to light must necessarily militate against the clearness of the result, to such an extent, indeed, as to render the practice impossible. A plate was coated with an unwashed emulsion, and placed directly in the slide and exposed for an out-door view, the time given being more than ample to produce a picture under ordinary conditions. After exposure it was well washed and a normal developer applied for at least double the time that would have sufficed to fully bring out the image under proper conditions, without, however, developing even a trace of the sky. The film was rinsed and again exposed for the same time, and, on reapplying *the same developing solution*, an over-exposed image was instantly produced. Another plate was coated in the diffused daylight of an ordinary room, washed in the dark room, and exposed for a similar time in the camera. Result: An amount of fog that could scarcely be deemed 'an advantage in the shadows.' In fact, a merely momentary exposure of the unwashed plate to very weak daylight is sufficient to give a very palpable veil. Hence, though an emulsion containing excess of bromide is slow enough to be useless in the camera without washing, it is not sufficiently so to bear coating in daylight.—SYNTAX.

Our Editorial Table.

SAMPLES OF CHRISTMAS CARD MOUNTS.

Bradford and London: Percy Lund & Co.

MESSRS. LUND, as is their annual custom, send us a number of samples of mounts, suitable for bearing photographs, inscribed with Christmas and New-year's greetings. They are simple but elegant in design, and in such variety of form and tint as to lend scope for the gratification of all tastes. The custom of sending one's friends mounted photographs, as emblematical of good wishes, at the close of the year, is a pretty one, and is much encouraged by those who lay themselves out to supply suitable mounts.

THE PRIMUS LANTERNIST'S POCKET-BOOK.

W. Butcher & Son, Blackheath, S.E.

BESIDES serving the purposes of a diary of engagements, this neat and convenient pocket-book gives several tables likely to prove

serviceable to lanternists, and provides spaces for noting the quantities of gases used and other memoranda. Lanternists will find it well worth pocket space.

A HOLIDAY TOUR IN AND AROUND WHITBY.

By H. S. FORMAN. Bradford and London: Percy Lund & Co.

MR. FORMAN had his camera with him during his sojourn in Whitby and its neighbourhood, of which he writes with great appreciation and sympathy. Some charming photographs of the old world fishing town on the Yorkshire coast, studies of fishermen, their women folk, children, and surroundings, and views of some of the scenery in the immediate district, illustrate the little book. The blocks are printed in ink of a warm colour, and the book delights the eye with its pleasing get-up, paper and printing being of the best.

MESSRS. PENROSE & Co., the well-known process house, send us two minute pocket-books, which the process man should find serviceable. One, compiled by Mr. F. Godfrey Cole, is a ready reckoner for calculating the number of square inches in blocks, stereotypes, and electrotypes. This gives the information wanted at a glance. The other briefly tells how to use the chief apparatus necessary in the production of a half-tone block, and is full, from cover to cover, of sound practical hints.

How to be a Successful Amateur Photographer.

By W. J. Lancaster, F.C.S. Birmingham: J. Lancaster & Sons.

Mr. Lancaster's little book is in its sixtieth thousand, which says a great deal for its popularity and value. The beginner will find it a useful guide to the rudiments of photography. It includes several reproductions of photographs taken with the well-known and widely used apparatus of the firm, and is altogether a handy primer to place in the way of the photographic novice.

Formulaire des Nouveautés Photographiques.

By Georges Brunel. Paris: J. B. Baillière et Fils.

M. Brunel's book, which has 144 illustrations, is practically a compendium of what is new in photography during the last two or three years. Thus, in the apparatus section, there are detailed descriptions of the latest introductions, chiefly of French origin, and a like office is performed with regard to receipts and formulæ, drawn from many sources. The work extends to nearly 300 pages, and must have cost its author a great deal of labour and research in its compilation. It forms one of a series of books of useful knowledge, and has been brought well up to date, radiography and colour photography occupying much of its space.

Catalogue Received.

J. E. Hill, 5, Chancer-place, Bradford.

Mr. Hill's list is devoted to club portrait work, enlargements in various kinds of printing, oil work, &c. His prices appear to be reasonable, and he appeals to the trade only.

Fallowfield's Photographic Remembrancer.

J. Fallowfield, 146, Charing Cross-road.

The latest number of this useful, and now very old, friend has reached us. Mr. Fallowfield well maintains the charter of telling the world what is latest and newest in photography. The *Remembrancer* particularises many items of apparatus and photographic sundries, handy alike to professionals and amateurs. As usual, it is issued gratis to applicants.

Enameline Miniatures.

Mrs. L. M. Williams, Camden-place, Bath.

Some specimens of enameline miniatures have been submitted to us by Mrs. Williams. Their distinctive feature is that the colouring is applied to carbon bases, thus avoiding the risks of impermanency. The carbon prints are specially prepared for this process, and the oil colours are applied to both the back and the front of the picture. Most charming results of a highly artistic nature are produced by Mrs. Williams's method, which should help to give increased popularity to coloured miniatures. Professional photographers will find the charges extremely moderate.

News and Notes.

The Annual Exhibition of the Romford and District Photographic Society will be held in December.

Fire at a Photographer's.—We are sorry to learn that on Saturday, the 5th inst., the premises of Mr. H. J. Godbold, photographer, of Hastings, were destroyed by fire.

Mr. J. Laing, Photographer, of Castle-street, Shrewsbury, is retiring from the business, which he has carried on thirty-three years. His successor is Mr. R. L. Bartlett, who was in Mr. Laing's employ as chief operator for eighteen years.

The Photographic Club.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock on Wednesday evening, September 23. Subject for discussion, *Halation, its Cause and Cure.*

According to a paper on "Explosion and Detection of Acetylene in Air," by Prof. F. Clowes, mixtures of air with 3·81 per cent. of acetylene are explosive. The best method of estimating acetylene in air is based on the examination of the change occurring in a hydrogen flame when such air is passed over it.

It is stated that important improvements in Röntgen photography are announced from Berlin. The most interesting is a simple method of photographing the stomach and intestines. It is only necessary for the patient to drink some harmless solution of mineral salt, such as lime water, which is as impenetrable as bone to X rays, and excellent results are obtained.

Aintree Photographic Society.—This Society will hold their Third Annual Exhibition of Photographic Work and Home Arts and Industries, including Amateur Painting by local artists, in the Aintree Institute, Aintree, near Liverpool, on Thursday and Friday, December 3 and 4, 1896. The Judges in the Photographic Section are Messrs. T. F. Floyd and F. Anyon (members of the Liverpool Amateur Photographic Society). The Exhibition Secretary is Mr. E. P. Heron, 2, Tilney-street, Orrell-park, Aintree, Liverpool, of whom entry forms and particulars may be had.

City of Manchester Municipal Technical School.—During the session 1896-97 a series of lectures on Photography will be delivered by Mr. C. F. S. Rothwell, F.C.S. The first course comprises thirty lectures, and is suitable for those just beginning the study of the subject, either as apprentices or amateurs, whilst the second or advanced course, also comprising thirty lectures, is intended for those already familiar with the processes described in the first course. The lectures will be illustrated by the most modern apparatus, and each process will be practically demonstrated. Towards the end of the session it is intended to arrange a few photographic excursions, to take place on Saturday afternoons. Particulars may be had of Mr. J. H. Reynolds, Director and Secretary, at the School, Princess-street, Manchester.

By command of the Queen a Royal warrant has been sent to Mr. Horatio Nelson King, appointing him Architectural Photographer to Her Majesty. We learn that Mr. King was summoned by telegraph from Windsor to photograph the recent Royal garden party at Buckingham Palace, also to photograph the private chapel at the same place immediately after the wedding, the results in each instance giving great satisfaction. This must be very gratifying to one who, for upwards of forty years, has worked for the Queen to find he has not been forgotten. Mr. King, in a note to us, said: "It may interest you to know that to-day I completed my 280th journey to Windsor Castle, doing special work at the Albert Memorial Chapel, the journeys extending over twenty-five years, and the railway distance 14,000 miles," a record we do not think can be equalled by any other artist.

The most powerful light-house in the world is that which is now more than half finished, on Penmark Point, Department of Finisterre, and will probably be inaugurated at the end of next summer. The height of the tower is 63 metres (says a contemporary), which will enable it to be seen during the day from a distance of 30 kilometres in fine weather. During the night its light will be visible for 100 kilometres. The great illuminating power of the light will be realised by means of the apparatus, inaugurated in France in 1892 at the Hève Lighthouse, with its lightning flashes. The principle on which these lightning flashes are based is that a flash of lightning lasting no more than one-tenth of a second suffices to produce on the retina its complete effect. Starting from that principle, the new light-house will send flashes of concentrated light over the ocean every five seconds, though they will last but one-tenth of a second. The Penmark Light will have cost, when completed, 24,000*l.*, half of which is provided by the State, and half by a legacy from the Marchioness de Blocqueville, a daughter of Prince D'Eckmuhl.

Acetylene Poisoning.—At a time when great efforts are being made to advance the industry of lighting by acetylene, says a correspondent of the *English Mechanic*, it is interesting to have some data as to the hygienic properties of this gas. Some investigations have just been made on the subject by M. Gréhant, Professor of Physiology in the Natural History Museum, and their results should be known to the public. M. Gréhant has first studied the subject from its poisonous point of view, and, contrary to former assertions, has found that acetylene is poisonous when taken in any quantity whatever, but in the same way as carbonic acid gas, *i.e.*, an unbreathable gas, and not as carbonic oxide, or a poison properly so called. In other words, to be suffocated, one must take a mixture of 30 to 40 parts of acetylene to 60 or 70 of air; but, after a partial poisoning, the blood very rapidly gets rid of the unbreathable gas. In the second place, M. Gréhant has found that, when combustion is complete and perfect, the products of combustion do not contain the least trace of carbonic oxide—a fact which is very favourable to the use of the new gas. But one must always bear in mind that acetylene, when burnt badly, liberates a quantity of carbonic oxide, such a formidable poison, and care should therefore always be taken not to employ defective apparatus. An important fact in connexion with the employment of this gas in public and private buildings is that mixtures of acetylene and air give much more violent explosions than mixtures of ordinary coal gas and air. These mixtures are explosive from 1 part of acetylene to 3 of air, to 1 of acetylene to 19 of air, while mixtures of coal gas and air are explosive only between the ratios of 1 to 3 and 1 to 11. A mixture of 1 part of acetylene to 9 of air gives the most violent explosion. The light given by acetylene is such that, if one stares at an ordinary bat's-wing burner for one or two minutes, a very bright image is left on the retina, which lasts for an unpleasant length of time. Care must be taken, therefore, in lighting schoolrooms or offices by acetylene, not to use a light which is too strong for the eyes, and inventors should devise some satisfactory means of modifying the light.

Patent News.

The following applications for Patents were made between August 31 and September 5, 1896:—

Viewing Zoetropic Pictures.—No. 19,181. "An Apparatus for Viewing Chrono-photographic or Zoetropic Pictures in an Ordinary Optical Magic Lantern." C. Wray.

Stereoscope.—No. 19,373. "An Improved Form of Stereoscope, Convertible into Spectacles, Spectacle Stereoscope, Hand Magnifier." J. Wilkinson.

Animated Photographs.—No. 19,146. "Apparatus for Taking and Projecting Animated Photographs." Complete specification. L. Korsten, G. Melies, and L. Reulos.

NEGATIVE HOLDER.—No. 19,588. "Improved Holder for Photographic Negatives and Films." C. E. FEW.

DRYING RACK.—No. 19,676. "An Improved Drying Rack for Photographic Plates and the like." D. ALLAN.

PRINTING FRAME.—No. 19,679. "An Improved Printing Frame for Photographic and other Purposes." D. ALLAN.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK

September.	Name of Society.	Subject.
21	Bradford	*Figure Studies and Pictorial Portraiture.* P. R. Salmon.
21	North Middlesex	*Platinotype.* J. W. Marchant, F.R.P.S.
22	Birmingham Photo. Society	Exhibition of Apparatus.
22	Dulwich	Demonstration of Lantern-slide Making. S. J. Withers.
22	Hackney	*Travels in Sicily.* A. L. Henderson.
23, 24	Ashton-under-Lyne	Exhibition of Prints by the Members.
23	Leeds Camera Club	*Toning of Platinotype Prints.* Rev. J. Beanland.
23	Photographic Club	Halation, its Cause and Cure.
24	West Surrey	Annual General Meeting.
26	Birmingham Photo. Society	Excursion: Lesmington and Offchurch. Leader, E. C. Middleton.
26	Borough Polytechnic	Excursion: Northwood and Moor Park
26	Darwen	Exc.: Turton and Jumbles. Leader, John Broome.
26	Leytonstone	Exc.: Valley of the Roding. Leader, Dr. W. P. Turner.
26	South London	Excursion: Battersea Park. Leader, F. W. Grigg.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

SEPTEMBER 10,—Mr. T. Bedding in the chair.

Mr. HODDLE read a paper on—

ACETYLENE GAS. [See page 602.]

During the reading of his paper, Mr. Hoddle showed the operation of converting the calcium carbide into gas by immersing a piece in a vessel of water, when, on the application of a light, it burst into flame. The outside cylinder of the apparatus was filled with water up to a line marked inside, and the carbide receptacle, which is pierced at the bottom so as to give the water access to its contents, was charged with a quantity of the carbide and securely fastened when it was inserted in the apparatus, and the gas began to form. It took five or six minutes to get a perfect flame owing to the presence of an excess of air in the machine which had to be got rid of. It had been said that a mixture of air with acetylene was very explosive, but he had failed to produce any such thing under any conditions. The lecturer showed the difference in the heat of the flame that exists between pure acetylene and when mixed with air, the heat of the former being noticeably less. He also showed a lantern jet fitted for the use of this gas, in which the burners were so disposed that the flame of one was flat with the condenser and the other at right angles, which arrangement was claimed to be more advantageous. A special fitting carrying twelve burners for photographic work was next shown at work, and specimens taken by its means. In taking these a space of about eight feet separated the sitter from the source of light, and this, with an exposure of four seconds at *f*-8, produced satisfactory results.

Mr. HENDERSON mentioned a case where the burners had been very quickly choked up, and asked the reason.

Mr. HODDLE could not understand it, unless the arrangement for cooling the gas was imperfect. He further replied that there was no gain in combining coal gas with acetylene. He showed the effect of running too many lights from a generator constructed to supply only a certain number, the light after a time getting jerky owing to the gas being consumed before quite cool.

Mr. HADDON suggested that the choking of the burner was due to overheating of the burner, which caused a change in the nature of the acetylene.

Mr. BANKS had compared the actinic power of acetylene with an oxy-hydrogen blow-through jet, and was understood to say its power was about two-thirds of the latter.

Mr. HODDLE said that Mr. Ives had stated it to be equal to the Welsbach light.

The CHAIRMAN had seen it pitted against an oil lamp and an incandescent light, but found it much whiter than either.

PHOTOGRAPHIC CLUB.

SEPTEMBER 9, Mr. Newell in the chair.

The HON. SECRETARY made several announcements with regard to the forthcoming session, the programme for which promises to be of a satisfactory nature.

Mr. W. D. Welford showed two panoramic views of Cumberland Fells. These consisted of two series of five pictures each. The negatives were made with a half-plate camera and a twelve-inch focus lens.

An interesting discussion upon the general principles underlying the production of panoramic photographs occupied the meeting. It was generally agreed that a series of pictures made on flat plates, and mounted so as apparently to join, would be unsatisfactory and untrue. The better method is to use a curved plate, as in the original panoramic camera, and to bend the resulting picture to a similar curve. It was suggested that, in cases in which it is desired to follow the easier method, more satisfactory results are obtained by allowing a space of about one-eighth of an inch to separate each photograph. This permits each picture to be looked at separately and from its proper point of view, that is to say, from a position opposite to it. At the same time, there is an appearance of panoramic continuity. Mounted in this way, panoramic views do not obtrude any technical discrepancies in tone or colour to so great an extent as they do if mounted in close juxtaposition.

MANCHESTER PHOTOGRAPHIC SOCIETY.

SEPTEMBER 10,—The President (Mr. H. M. Whitefield) in the chair.

Mr. WHITEFIELD opened a discussion on the

FIXING AND WASHING OF PRINTS,

including the various kinds of print-washers. He (Mr. Whitefield) in his opening remarks, stated that twenty-six years ago the time taken in washing prints was much longer than at present, as it has been demonstrated that quick but thorough washing is the best to ensure permanency in both albumen and gelatine prints; also, in the case of gelatine papers, there is a certain amount of alum in the emulsion, which, if subjected to prolonged washing, is driven out, and the film consequently becomes soft and awkward to handle. The Chairman stated that a few years ago Mr. Edwards showed at one of the meetings a washer with wooden trays with gutta-percha netting and syphon automatic changing. He now showed the members a washer on somewhat the same lines, but a more perfect changing apparatus, as Mr. Whitefield had tried most of the washers on the market, and had come to the conclusion that there was not a perfect automatic washer on the market, and that syphon washers were not good to use on account of the water running out and leaving the prints out of the water until filled up again.

Mr. BLAKELEY did not agree with Mr. Whitefield. He had had a syphon tank in use for twenty years, and never found it choked, or any of the disadvantages which the Chairman mentioned. An article describing Mr. Blakeley's washer was published in THE BRITISH JOURNAL OF PHOTOGRAPHY for January 2, 1880.

Mr. J. MORLEY BROOK uses two dishes, and transfers the prints from one to the other, changing the water each time.

Mr. S. L. COULTHURST adopts the same plan, also occasionally squeegeeing the prints on plate glass in order to force the moisture out as much as possible.

Mr. HARRY WADE stated that, when there is a large batch of gelatine prints to be fixed, it is better to use two baths, as the first becomes discoloured and contaminated. He also used the dish method of washing, giving twenty changes from dish to dish.

North Middlesex Photographic Society.—September 14, Mr. H. A. Rutt in the chair.—Mr. A. J. D. Forster, 102, Florence-road, Stroud Green, and Mr. H. Cronch, 30, Beaumont-road, N., were nominated for membership. Mr. C. M. Hamm was duly elected a member. The PRESIDENT (Mr. Mummery) announced that the annual Exhibition of members' work was fixed for November 30 and December 1 and 2, and the day for sending pictures in was Friday, November 20, up to nine o'clock. The report on the Greenford and Headstone Manor outings having been given, Mr. TAYLOR, of the Autocopyist Company, proceeded to give a demonstration on the Photo-autocopyist. He explained the process, and pulled off several prints, which were passed round. He also showed how the process could be used for copying line drawings and writing, instead of having special apparatus for both processes, the main difference being that the gelatine-coated film was simply wetted with water and wiped dry, and the paper, written with special ink, laid down for one minute, and the film inked up, and a copy was obtained by using a roller instead of a press.

Leeds Camera Club.—The opening of the session 1896-97 took place on Wednesday evening last at the Grand Restaurant, Boar-lane. There was a crowded and enthusiastic attendance. The chair was occupied by Major Norwood, and supported by the Rev. — Addison (President of the Wakefield Photographic Society). By the kindness of Mr. J. H. Rigg, an exhibition of the cinematograph was given, and gave unbounded satisfaction. A very successful smoking concert was held afterwards, when songs and recitations were given by Messrs. Smith, Swinden, Palliser, Gaunt, Rathmell, and Crawshaw. Professor Needham ably presided at the piano. A hearty vote of thanks was given to Mr. Rigg and the *artistes* for their entertainment. The new syllabus was distributed amongst the members, who were delighted to find such an interesting and instructive programme placed before them, and it argues well for the success of the Club. Meetings take place every Wednesday evening until the end of April next year. Next week a lecture and demonstration on the wet-collodion process for lantern slides will be given by Mr. J. W. Garbutt.

1896. FORTHCOMING EXHIBITIONS.

Sept. 24-Nov. 7	.....	Photographic Salon, Dudley Gallery, Piccadilly. Alfred Maskell, Dudley Gallery, Piccadilly.
,, 28, 29	.....	Lewisham Camera Club. H. M. C. Sprunt, 192, New Cross-road, London, S.E.
,, 28-Nov. 12	...	Royal Photographic Society. R. Child Bayley, 12, Hanover-square.
December 3, 4	.....	Aintree Photographic Society. E. P. Heron, 2 Tilney street, Orrell Park, Aintree, Liverpool.
Dec. 1896-Jan. 1897		Bristol Internationa'.

Correspondence.

☞ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

"WHO INVENTED THE KINESIGRAPH?"

To the EDITORS.

GENTLEMEN,—I do not like to trespass on your space in connexion with what may seem a purely personal matter; but my attention has been called to an article which appeared in THE BRITISH JOURNAL OF PHOTOGRAPHY, in which the question is asked, "Who invented the kinetoscope?"

The writer of the article (Mr. A. T. Story) says: "The newspapers have set their busy pens to work upon it, and Mr. Edison has again been deluged with eulogistic ink. But is Mr. Edison entitled to this praise?"

Perhaps you will allow me to state that, years before Edison took out a patent in connexion with "moving pictures"—before he had even got so far as to throw out his usual hints in the press as to what he was going to do in the matter—I had invented the kinesigraph, as I called it, patented it, made it, and worked it.

Close behind me came Mr. Friesee Greene; then came Mr. Edison with his kinetoscope toy; and finally M. Lumière, Mr. Paul, and Mr. Acres some few years later still.

Not only was I the first to *patent* the invention, which, so far as credit is concerned, is a secondary matter, but I was the first to invent it by more than a dozen years. As long ago as 1877 I had a model made, and the whole thing was described in *Nature* in almost the identical words in which Mr. Edison announced his "coming" marvel to an expectant world in 1892.—I am, yours, &c., WORDSWORTH DONISTHORPE.

Somerlea, Reigate, September 12, 1896.

PHOTO-CHEMISTS—PHARMACEUTICAL CHEMISTS.

To the EDITORS.

GENTLEMEN,—I do not think Mr. Hampson's two letters improve matters; he has not travelled much amongst them, or he would have seen a great lack of chemical knowledge if questioned on any article out of their special lines. Travelling amongst them for over thirty years, I have often been amused by their replies to amateurs, and, with all our photographic literature, it is necessary for a successful dealer to help them over many difficulties.

In one of Mr. Hampson's, or some other pharmaceutical chemist's earlier letters he spoke of these chemists being the pioneers of photography. Now, I happen to have all the ALMANACS of the BRITISH JOURNAL from the first issue, bound up with the advertisements, and, looking over one of those small numbers when they were the size of Letts' waistcoat pocket diary of over thirty years ago, I find they were far from the pioneers; in fact, in running over the names of twenty-six advertisers, there were only three of them chemists, and they were something more than the ordinary chemist, because they were also dealers in scientific apparatus, and therefore justly included photographic apparatus.

Who have we to thank for the cutting prices now ruining the photographic trade but the chemists? Only lately an amateur had bought a Frena of a cutting chemist, who could neither give him directions nor show him how to get inside, and the amateur had to take it to a dealer to get him to open it. In a town of 60,000 a pharmaceutical chemist was not content with selling gold chloride (best) at 1*s.* 9*d.* per 15-grain tube, but, to get the custom from a dealer, gave in with it an ounce of either soda acetate or phosphate. The dealer, instead of retaliating, sent all his customers to the chemist, and told them they could get an ounce of any salt given in; this went on for a time, the dealer did not lose much, as the chemist soon shut up.

Now, in the name of goodness, why should a dealer sell gold for less profit than a grocer gets on sugar, for the quantity sold 1*s.* 10*d.* is quite little enough?

Dealers, if they wish to use the term, need not be afraid to style themselves photographic chemists, the Society cannot prevent them. It is only in connexion with selling poisons that they can step in; and surely poisons are so few, that no one need care; either do as they do in France or send it by post, or, if a good customer, make them a present of it. As sulphocyanide is not a scheduled poison, there is only the mercury bichloride to trouble them, and by putting up the uranium intensifier it will not be needed.

From all sides this year has not been a very good one for photographic dealers, and my advice is not to cut down prices to the same level as the chemists but to make themselves thorough masters of their business, try everything thoroughly, be able to answer every question, and he need not fear the poison law or any other monopoly.—I am, yours, &c.,

MEDICO.

TAKING PHOTOGRAPHS FOR NOTHING.

To the EDITORS.

GENTLEMEN,—It is more than probable that the firm of diarists will have changed their opinions before this respecting the views of "the leading photographers of the kingdom," judging by the correspondence that has appeared in the pages of our (professional) JOURNAL, aided too by the influence of our Editor, who, in answer to a correspondent a few issues back (August 14), plainly told him that competitions had no place in his JOURNAL. Thus, much good, I hope, will unwittingly accrue from the firm's action, and that these unhealthy schemes will receive a "scotch" which may eventually evolute to their death. To this end, for some time past, I have placed my orders only with such firms as hold aloof from free coupons and "prizes" to users of our material schemes. So, consonant therewith, I declined the firm's offer with an indignation felt, if not expressed, and shall still practise and endeavour, as of yore, to disseminate the leaven of my views, and so another name is engraved within "the book and volume of my brain."—I am, yours, &c., W. BARRY,

President National Association of Professional Photographers.

September 14, 1896.

AN ANTI-HALATION SECRET.

To the EDITORS.

GENTLEMEN,—Place two thickly coated plates together in single slide, both with their films facing the lens, so that the back film may receive the superfluous light its front neighbour can well spare. This is a secret worth —— at least.—I am, yours, &c., ANTIHUMBUG.

ABOLISH THE PATENT LAWS.

To the EDITORS.

GENTLEMEN,—There is a beautiful simplicity about your correspondent's letter under the above heading in your last issue, his reference "to the existence of a higher intelligence" being an excellent argument in favour of permitting every one to avail himself of—or, in plain Anglo-Saxon, steal—the fruits of another man's labour. Your correspondent might go a little further and apply the same argument to literature and painting—why should not any one be allowed to copy any work that he has a mind to? There is, however, a great difference between the laws of this country, as relating to literature and painting (including photographs), and those relating to inventions. The law of copyright, although not perfect, is comparatively simple; whereas, after an inventor has obtained an English patent, he finds that he has published his ideas to the world through the Patent Office, and all he has gained is the privilege to enter an expensive law suit against infringers. Your correspondent, however, may take heart, for, "owing to the existence of a higher intelligence," there are thousands of harpies and thieves dodging around to see how much of other people's ideas they can appropriate and yet keep outside the law's grasp. You may, by sharp practices, steal another man's brains to any extent you like; but, if a starving beggar stole a piece of bread, the law in all its majesty would be down on him.

It might interest your correspondent, and some of your readers, to hear some of my experiences in connexion with "animated photography." I do not profess to be the original inventor of animated photographs, because it is exceedingly difficult to know what the other men have thought of; but I do know that, twenty-five years ago, I made wheel-of-life pictures *drawn* partly from photographs, and I tried to make them by photography purely; but, as I could only get twelve pictures at that time, the incident lasted only a second or two. I dropped the matter for a number of years, and then the work of Muybridge gave me a renewed interest in it. In 1893 you will find that I took out a patent for an apparatus for taking and showing pictures in rapid succession. I also successfully photographed the Oxford and Cambridge boat race in 1895, also the Derby of that year, and I think I am quite safe in the assertion that I was the first to successfully take such photographs. But to come to the object of my letter. In order to develop and print these long bands of photographs, special means had to be adopted. I had to find out how, and did so. I took into my employ men who knew no more about the subject than my boot knows, I taught them everything they knew, and, as business increased, I took on other assistants, having to teach them also. Business called me away for a week or two, and I learned afterwards that a youth had been a constant visitor in my absence, and, by a curious coincidence, on the discontinuance of these visits, others learned how to produce these pictures. The private address of one of my assistants was also discovered, and he was called upon, about eleven o'clock one night, and an offer of employment made to him. Comment is needless.

I might publish a great deal more in the same strain, but I feel I must not trespass on your valuable space further. I only wish to warn other inventors to be very careful to properly protect their inventions before allowing any one to see their models and drawings, and, if possible, to keep the various branches of their work apart. *Verb. sap.*

I am yours, &c., BIAT ACRES.

SUNDIALS.

To the EDITORS.

GENTLEMEN,—I should be very much obliged if any reader who has a photograph of a sundial—or a print in which a sundial forms any considerable portion of the picture, would favour me with a copy, in return for which I shall be pleased to exchange other prints. Thanking in advance any reader who may so oblige,—I am, yours, &c.

Stanmore-road, Birmingham. E. C. MIDDLETON.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & Co., 2, *York-street, Covent Garden, London.*

RECEIVED.—JAQUES; J. A. T.; and others. In our next.

ADDRESS WANTED.—A. GAUNT. The address is—Care of the Gem Dry Plate Company, Villiers-road, Willesden Green, London, N.W.

SPOTS ON PRINTS.—H. SHOEBRIDGE. You must give us fuller particulars as to the mountant employed, method of washing, &c., before we can hazard an opinion.

FREE-PORTRAIT SCHEMES.—R. W. HOWES. We have frequently referred in these pages to these free-portrait schemes, which could not live if the public were not so gullible.

PHOTOGRAPHING IN HYDE PARK.—C. STUART says: "Would you inform me how I can get permission to photograph in Hyde Park?"—In reply: Apply to the Secretary, Her Majesty's Office of Works, Whitehall, S.W., enclosing a stamped envelope.

EMPLOYER AND ASSISTANT.—PRINTER. No specified time, whether months or years, will entitle you to "compel" your late employer to give you a reference. Giving a character is quite optional on the part of an employer, though it is seldom refused.

WASHING TROUGH.—T. WILKINS. Metal vessels, unless they are enamelled or japanned, are not to be recommended for washing prints. Enamelled iron dishes are not good for silver solutions, because the enamel is seldom so perfect that the silver will not find its way to the baser metal.

GERMAN CUSTOMS HOUSE.—C. N. If the boxes are labelled photographic plates, and you explain that they will be spoilt if exposed to light, you will have no difficulty in getting them through the German Customs House—less, indeed, than you may perhaps experience in getting them through the English Customs on your return home.

PORTRAIT LENS FOR LANDSCAPES.—C. BENTON. You have made a mistake, the back lens of a portrait combination is of no use for landscape work. It is the front combination that must be used for that purpose. The function of the back lens of the Petzval form of instrument is to correct the errors of the front one, so that the combination can be worked with a large aperture.

TO PRESERVE GELATINE.—VERDES says: "Will you be so good as to inform me how to preserve gelatine for optical mounting? A recent preparation of mine became quite bad in ten days' time, and I am at a loss to know what to add to it that will not damage the print."—In reply: The addition of a little glycerine and methylated spirit to the gelatine when dissolved will probably answer.

ELECTROTYPING.—T. WARNER. The form of battery most in use by practical electrotypers for depositing copper when a dynamo is not available is the Smee form. It is found more economical in working, and more convenient to deal with than the Daniel battery. The Grove or Bunsen is better suited for steel facing than for depositing copper. For that purpose either is better than the Smee form.

MOUNTS.—T. WALTON says: "I have been told that prints mounted on chocolate mounts are sure to fade. Recently I heard that these mounts were the safest of all to use. Can you give me any idea which is right?"—Either may be right, or either may be wrong. "Chocolate mounts" are not always surfaced with the same pigment.

S. N. J.—We have carefully read your letter, and are sorry we may not print it, as it might have elicited a number of interesting opinions. We fear you have no legal remedy, although, under the circumstances, it is decidedly galling to have a slur cast on the quality of your work. We should advise you to take no notice of the matter. Please send us the name of the paper—if possible, a copy—as we should like to make a reference to the subject.

A RATING QUESTION.—IN DOUBT.—If the studio is a "converted caravan on wheels," standing in the garden, we should say it is not rateable—that is, if it is a *bonâ-fide* vehicle which can be taken from place to place. If, however, it is permanently placed in the garden, from which it cannot be moved without disturbing a fence or wall, and is used for business purposes as a photographic studio, the case may be different, and, as the parish authorities assert, subject to rate.

LEMANE'S PHOTO-ENGRAVING.—C. R. CHAPLIN says: "Kindly inform me where I can obtain the book mentioned by you in this week's issue, *Photo-engraving Made Easy*, by Lemane, and price of same."—In reply: As stated in our review of the book, it is published by Messrs. Harrington & Co., Sydney, New South Wales, price 1*s.* It is a long way to send, so you had better buy Verfasser's book, published by Messrs. Percy Lund & Co., Amen-corner, E.C.

STUDIO AND BLINDS.—S. B. The form of studio as shown in the sketch cannot be patented, neither can the blinds be, as both are old. The studio formed the subject of a patent by Mr. Van der Weyde many years ago, and the louvre form of blinds or screens is still older. It is true that you can patent the studio the same as one can anything else, but the patent would be invalid. There would be no legal obstacle to any one constructing a similar studio and fitting it with the same kind of blinds if they chose, but it is doubtful if any one would desire to do so.

NEGATIVES BROKEN IN TRANSIT.—A. W. & Co. We are afraid you will now get no compensation. As the enlargers say they were properly packed when they dispatched them, they will, of course, deny responsibility. As your reception-room attendant could hear broken glass in the package when it was delivered, she should not have accepted it or signed for it except as received damaged. As it is, the receipt implies that the parcel was received in good condition. As a fortnight has elapsed, and no complaint made, we expect the railway company will now entertain no application for compensation.

FORMALIN FOR HARDENING PRINTS.—J. L. CLARKE says: "Referring to your article of April 16, 1895, on formalin as applied to negatives, would you mind telling me, in your Answers to Correspondents, whether formol is a better substitute for alum for hardening prints—whether, after the final washing, the application of formol would produce any deleterious compounds likely to injure the conservation of the prints?"—In reply: We have no practical experience of formalin for the purpose named, but *theoretically* it is to be preferred to alum. You would require to employ it in a very dilute state. We do not think it would create any deleterious compounds likely to injuriously affect the prints.

AIR BUBBLES IN LENSES.—A. BLAIR writes: "A friend of mine, while in Germany a few weeks ago, bought a lens made with the new Jena glass, but it has several small bubbles in it. The makers assured him that the bubbles would make no difference in the working of the lens; but surely they must. Does this not show that the Germans do not mind what they sell so long as they get the money?"—The air bells will, as the makers said, make no practical difference in the performance of the lens. With some kinds of the Jena glass it is impossible to get it free from air bells; consequently lenses made with it, whether in England, France, or America, have them, but they do no harm. Can you, or your friend, find any ill effects from them?

UNMOUNTING GELATINE PRINTS.—M. P. says: "I should feel very greatly obliged if you would kindly advise me concerning the following matter: I have mounted a very highly glazed print. Whether gelatine surface (which I think it is) or some kind of printing-out paper I do not know, but in drying it has "rucked up," and therefore is useless for copying, for which purpose it was mounted. In mounting, ordinary starch was used, and was mounted dry, great care being exercised. I was afraid to rub it down between blotting-paper as in silver prints. It is a very valuable print, and cannot be replaced, and I want to know, first, How can it be removed from the mount with safety? secondly, how should it be remounted?"—In reply: I. So recently as August 14 (see the JOURNAL of that date, page 523) two methods of unmounting gelatine prints were given. We refer you to that number. 2. To mount, squeegee down to remove the cockling, and then proceed to mount in the ordinary way.

TELLING THE COLOUR OF AN ORIGINAL FROM THE NEGATIVE.—J. W. BENNETO says: "I notice in your reply to a correspondent last week, who aska 'if it is possible to tell the colours of an original from the examination of the negative only,' you state 'it is generally possible to do so.' This reply has caused me a considerable amount of surprise, for, after nearly twenty years' experience of photography, obtained in London studios and elsewhere, I am unable to do so. Now, as you say it is possible to do so, I have this day, in the presence of four gentlemen, taken a negative on an orthochromatic plate (Lumière's Series A) of twelve colours on a white card, each colour numbered, and which I herewith send you, and ask you if you will be good enough to name these colours from the examination of the negative only, and, should you do so, I will forward you one guinea for your trouble. The coloured card has been sealed up in the presence of the four gentlemen, and will not be seen or handled by any one until after your reply, which I should be pleased to see through your columns if this is agreeable to yourself. The negative was taken through a yellow screen."—In reply: We adhere to our opinion that, "*generally* speaking, it is possible" for a photographer to tell the colour of an original from an inspection of the negative. Whether we, or any individual, could do so in a *particular* instance is another matter. It is *possible* to take photographs in natural colours (*vide* Lippmann's process), but experience shows that it is enormously difficult to repeat his results—or devise another process. As to Mr. Bennetto's offer of 1*l.* 1*s.*, we should hardly have thought it necessary to remind him that neither our position nor our inclination would permit us to avail ourselves of it.

THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 1899. Vol. XLIII.—SEPTEMBER 25, 1896.

Contents.

OUR FORTHCOMING ALMANAC.

The time of year has arrived when it is necessary for us to take in hand the preparation of The British Journal Photographic Almanac for 1897. A feature of the volume for the past thirty years has been the co-operation of numerous friends and readers of the Journal, and the Editor takes the opportunity to express the hope that the support so kindly placed at the disposal of his predecessors may be continued to him.

We especially invite contributions on topics of practical interest, and should feel obliged if the articles and any accompanying sketches are sent to us at the earliest possible date.

Secretaries of Societies, and especially of those established since the appearance of the last Almanac, will oblige us by forwarding lists of officers and other details for inclusion in the Directory of Photographic Societies, in order that the list may be made as complete as possible.

The Publishers wish us to remind intending advertisers that the announcement pages of the Almanac are already filling rapidly, and that, to ensure insertion and good positions, orders and copy should reach them without delay.

EX CATHEDRÂ.

Mr. C. E. Corke, photographer, writes us in reference to some comments made on his work by a non-photographic contemporary: "I have a series of registered photographs, 12 × 10, of Knole, near Sevenoaks, and also the exclusive right, granted me by the owner, to take photographs of it. About three weeks ago a gentleman called on me to know if I would allow any to be published in the *Builder*. I told him my terms, &c. He then asked me to send a selection to the editor for him to choose from. I did so, and he retained two, and sent me postal orders for two guineas, the fee I asked, at the same time requesting me to sign a printed receipt, which he sent. I wrote him by return of post, acknowledging the receipt, but at the same time asking him for a letter agreeing to my conditions (which I had told to his agent), *i.e.* that the photographs were only to be used for the special purpose, and no other reproductions made, unless for reprints of the whole of the paper they were in. At the same time I stated that, if he refused my terms, and would return the photographs, I would return the two guineas.

* * *

"I received no answer to this letter, and after a week wrote again, asking for the same. Before an answer came a friend of mine brought me the paper in question, with the two views reproduced in process, and my name under them. But imagine my surprise when in the letterpress respecting them appeared the following: 'Unfortunately, even photography has been restricted to a local photographer, who exercises a monopoly, and whose photographs are very inferior to what we could have obtained if we had been at liberty to have our own photographs specially made.'"

* * *

We have before us silver prints of the negatives, and they strike us as being very good, and hardly deserving to be termed inferior, whatever the photographic abilities at the service of the *Builder* may be. Mr. Corke has all the more reason to complain of his work being condemned by our contemporary, inasmuch as he informs us that he did not submit it for reproduction, and, in fact, would have preferred not to have had his photographs utilised. We are confident that our professional readers will sympathise with Mr. Corke, whose admirable work has frequently earned commendation in these pages. Mr Corke makes the suggestion that in future, when photo

graphers are permitting their photographs to be reproduced by the illustrated press, there should be a stipulation protecting them from adverse criticism. But such a stipulation is, it may be hoped, unnecessary in the majority of cases.

* * *

The many friends of Mr. Alexander Cowan will be glad to hear that he is rapidly recovering from the accident he met with a few months ago. Mr. Cowan had the misfortune to have his leg broken through being knocked down by a hansom, and he was for some time prevented from attending to business. He is now able to get about, and in a short time expects to be completely well.

* * *

Acetylene for evening portraiture, or for use when lack of natural light in the studio obliges photographers to resort to artificial illumination, should be borne in mind by photographers as likely to prove extremely serviceable. At a recent meeting of a London photographic society photographs of good quality were shown that had been taken under very simple conditions. Twelve acetylene jets in the form of a ring, about a foot in diameter, the supply of gas coming from one generator, were utilised as the source of light, and placed within about seven or eight feet of the sitters. Fully exposed results of good quality were obtained in four seconds, using Ilford special rapid plates, and with a lens aperture of *f*-8. It would perhaps be preferable to split up this light, so as to make more than one source, and also to use some means of softening or diffusing it, as our experience shows that the bright flame given by acetylene is painful to the eyes. At any rate we commend the subject as well worth the attention of practical photographers.

* * *

We have been sent a copy of the *Western Mail*, which we observe makes an "extraordinary offer" to its readers. It undertakes to supply three-quarter life-size "crayon and Indian ink portraits" for six shillings and sixpence. A price-list of frames is also appended. The usual statement is made, that "these pictures, if ordered through artists in the ordinary way, would cost from two to three guineas." If that be so, we are sorry the *Western Mail* does not seize the opportunity of obtaining the market price for its enlargements.

* * *

We made allusion some months since to a London studio in which a system of foot lights was adopted for imparting to photographs of actresses the appearance of having been taken on the stage. Messrs. Langfier, of Glasgow, whose new and handsomely fitted studio was recently opened in that city, have extended this idea, and have provided a completely fitted stage, which is to be used for photographing theatrical subjects. It has a handsome proscenium, and sets of scenery, and is illuminated by incandescent lamps of an aggregate of 12,000 candle power. We congratulate Messrs. Langfier on their enterprise.

PANORAMIC PHOTOGRAPHS TAKEN IN SECTIONS.

Panoramic photography formed an interesting theme for discussion at a recent meeting of the Photographic Club, when one of the members showed some panoramas, each composed of four or five separate negatives. Now, nothing seems much simpler than to take a series, say, half-a-dozen negatives of a scene, print them, and then mount them in juxtaposition, to obtain a panorama including any desired angle. But, simple as it seems, as many know who have tried it in practice, it is by no means an easy matter to get half a dozen prints from as many different negatives of the same depth and tone, so that, when they are joined together, the junctions do not show more or less conspicuously—the former rather than the latter. Still the thing is possible, and many very satisfactory results have from time to time been produced in that way, and in very large sizes too.

One of the things which is, generally, very noticeable in joined panoramas, unless the negatives are taken with tolerably long-focus lenses for the size of plates used, is that the prints are darker at the margins than they are in the centres. Hence, when the prints are joined, there are alternate dark and light places throughout the length of the picture. The dark portions at the edges are due to the unequal illumination of the field of the lens, sometimes added to by inequality of the film at the edges of the plates. We shall not here discuss the question of panoramic and plane perspective, but give a few practical hints on the production of panoramas in sections.

One of the essentials to success is that the camera be planted perfectly level; another is that it can be freely rotated on its stand by loosening the screw, or by the turntable if it has one; and the centre of rotation should be as nearly as possible under the optical centre of the lens. On no account should the camera be otherwise moved between the exposures. The negatives should be taken quickly, one after the other, so as to secure equal lighting in all, and it is unnecessary to say that the same exposure must be given in each case. In arranging the camera for the different sections, a good margin should be allowed on each negative—that is, each should contain at either end a good amount of the subject of the next one. By this means the dark portions just alluded to may be discarded and only the best portions utilised. In this way the joins of half a dozen pictures can be more easily hidden than could four or five if nearly the whole of each were included. Before the camera is moved, after the negatives have been taken, it will be well to mark the spot, so that it can be replaced exactly where it was before in the event of any of the negatives turning out unsatisfactory. If it should happen that any have to be retaken, it is obvious that the same time of day must be chosen, otherwise the lights and shadows will not agree with those in the other pictures.

In the development of the negatives they must be made as nearly as possible of the same density and of the same character, *i.e.*, developed under the same conditions, or prints of similar tones will not be obtained. The prints may be made on any of the papers, but generally the most uniform results will be obtained on a printing-out paper, albumen by preference. The prints should be carefully printed to the same depth, and all toned in the same bath. The examination of the prints during the printing should be done in the dark room, and they should not be exposed to white light while toning, as even the slightest tint on the sky of one will prevent its matching the others when finished. It is very important that the paper for all the prints should be cut in the same direction from the sheets; otherwise, in mounting, when the prints are wetted with the mountant, they will be of different dimensions. The best way of trimming the prints, each of which contains some of the subject of its neighbours, is to accurately superimpose the duplicated portions, the one on

the other, and then cut through the two papers with a sharp knife. In this way perfect junctions are secured without further trouble. In some instances it is better to make the cut other than straight through the subject; but, as a rule, a straight cut through the sky itself is preferable.

The junctures in the sky are always more difficult to hide than they are in other portions of the picture, particularly if it happens to contain natural clouds, or the negatives print through in the sky. For this reason the sky is often blocked out entirely in all the negatives, so that it prints perfectly white. It may, however, be toned in afterwards, though it is obvious that it cannot be done with each print separately. The way to do it is to arrange all the prints on a flat board, and then cover them with a piece of glass to keep them in position. The sky can then be tinted in shading it as desired. In this way a uniform tinting will be obtained on all the prints alike.

Building up a panoramic picture in sections, by mounting the prints in juxtaposition by "butting" the edges, is very troublesome, and is rarely entirely satisfactory, owing to the joins not being perfectly hidden, arising from a difference of the depth or tone of the various prints. It was pointed out at the Club meeting, however, while this matter was being discussed, that a satisfactory and easy method of producing panoramas was, instead of actually joining the prints in mounting, to leave a small space between them according to the size of the pictures. In this way any slight discrepancy in depth or tone passes unnoticed, and, when the panorama is viewed from a distance, it appears as a continuous picture; and, when looked at closely, each section can be seen as a separate picture.

There are other ways of producing panoramas in sections, by which the joins may be more completely hidden than is possible in joining the finished prints, but space will not permit of a description of them in the present article.

The Recent Eclipse.—It is evident that we shall not be, as was at first thought would be the case, without good photographs of the recent eclipse, for the Russian observations, according to M. Tissorand, whose authority was M. Buckland, the Director of the Pulkowa Observatory, have met with a fair share of success, a number of successful photographs of the corona having been taken. Up to a very short time before the eclipse the sky was covered with clouds, but they cleared up sufficiently to enable good results to be obtained.

The Blue Sun.—So much doubt has been thrown on the existence of this phenomenon that it is a pity some hand-camera worker should not endeavour to secure a snap-shot on the occasions when it is observed, for, though, of course, the colour would not be seen, some of the attendant phenomena would be recorded, which would tend to confirm the actual existence of the effect, and possibly to throw light upon its cause. We are led to making these remarks through noticing the account, by Professor H. Mohn, of a recent observation of the phenomenon by Captain Salveson, of the Royal Norwegian Navy, who states that he recently saw the "blue sun" off the west coast of Norway at sunset. The sun at the time was quite clear. "It is curious," says *Nature*, "that this beautiful sight is so rarely looked for."

Gold Decoration.—Although the plan of printing of photographic mounts in bronze (or, as it is called, "gold") ink is fortunately far less adopted than once was the case, we are sorry to find it is not entirely banished from the studios of some photographers. It is true that special pains are taken, now the danger of the bronze is known to ensure the absence of any trace of powder from the surfaces of the mount, but it is not possible to entirely free the card from the deleterious substance, the mere packing and handling is sufficient to detach portions of the bronze, when, as every one ought to know, the print entirely loses its colour at each spot where a particle of the bronze touches. The best way to prove the existence of this danger is to mount a print on the back of a mount printed in gold and leave it in a damp place. In a week or two the name or design so printed will make its appearance in white, the metal having acted right through the paper on to the printed photograph.

Still, a little gold bronze for decorative purposes on photograph frames and otherwise is permissible, and some notes on the plans usually adopted for utilising the bronzes or gold powder, as they are so often termed, will be useful. This bronze can be had of a large variety of shades—gold colour from the palest yellow to the deepest gold tint, green bronze of various tints, and bronze of silver colour. Where no weathering is likely, a water vehicle is used; a mixture of dextrine and water of suitable consistency, to which has been added twenty-five per cent. of bichromate of potassium, is employed; about five times as much dextrine as bronze is needed. Dilute solution of water glass is also made use of where more permanent work is needed. Solution of shellac with borax is also used, an addition of one-half its bulk of spirit being found advantageous. We read, too, the following instructions, which, however, we think neither logical nor likely to be useful: Dissolve dammar in benzole, and neutralise with solution of potash by shaking together, and allowing to "separate." But, of all the gold paints ever brought forward and sold, the most popular is the "permanent gold paint," that has been an article of commerce for some time past. We have seen no formulæ published as to its mode of manufacture, but a close examination suggests to us that it is composed of gold bronze of a real gold shade, mixed with a solution of celluloid in amyl-acetate. Our readers may thus find a new use for the support in old-film negatives.

Are Röntgen Rays Material Particles? — Physicists are observing great caution in making any pronouncement as to what the Röntgen rays really are. For example, Professor Thompson, President of the Physical Section of the British Association, in his inaugural address, says: "We are not acquainted with any crucial experiment which shows unmistakably that these rays are waves of transverse vibration in the ether, or that they are waves of normal vibration, or, indeed, that they are vibrations at all. The two ways in which Röntgen rays differ from light is the absence of refraction, and perhaps of polarisation." But M. Tesla, whose coil is well known, and who is an authority of high value, gives his opinion without reserve. He thinks they are not vibrations, but are actual particles emitted in a somewhat similar manner to that predicated by the Newtonian theory of light. He witnesses that he can actually feel the effects of these material particles striking against his eye, and has noted the sensation he experiences when they come in contact with his brain. "There is little doubt now," he says, "that a cathodic stream within a bulb is composed of small particles of matter thrown off at great velocity from the electrode. . . . . But surely matter proceeding with such great velocity must penetrate great thicknesses of the obstruction in its path, if the laws of mechanical impact are at all applicable to a cathodic stream. . . . . I would not doubt that some matter is projected through the thin wall of the vacuum tube. The exit from the latter is, however, the more likely to occur, as the lumps of matter must be shattered into still smaller particles by the impact. From my experiments it appears that the lumps or molecules are indeed shattered into fragments, or constituents so small as to make them lose entirely some physical properties possessed before the impact."

THE TREATMENT OF OVER-EXPOSED PRINTS.

One of the greatest troubles in these days of rapid printing paper is the avoidance of over-printing when only a moderate number of printing frames have to be watched. In the old days of collodion

negatives, especially with pyro development, the general density was so great that, even in strong sunshine, an oversight of several minutes made very little difference, comparatively speaking, in the quality of the finished print; but now, with thinner negatives and vastly more delicate gradations, as well as much more rapid paper, a few seconds will often make all the difference between a good print and an inferior one, and, unless the very greatest care is taken, the loss from over-exposed prints forms a very serious item in the modern photographer's calculations.

Many have been the remedies proposed; but, although it is a very easy matter to simply reduce the prints, it is almost invariably at the expense of the tone. Treatment of the proof before toning nearly always exerts an injurious influence on the subsequent action of the gold solution; while, on the other hand, if the remedy be applied after toning to the image, composed partly of gold and partly of silver, the colour is altered in consequence of the removal of the metals in unequal proportions. Thus, if the silver be dissolved in larger proportion than the gold, as is usually the case, a bluer tone results, and the reverse is the case when the superficial layer of gold is attacked. How extremely small a proportion of the toned image consists of gold is proved by the simple experiment of bleaching a toned print with mercuric chloride, by which means the silver it contains is converted into chloride, and thereby rendered invisible, while the gold remains as an extremely faint stain, barely sufficient, in many cases, to indicate an image at all. The experiment shows, in fact, how delicate a matter it is to interfere in any way with a finished image, whose tone depends entirely upon the due proportionment of its metallic constituents.

In cases of very or comparatively slight over-printing the simple device of treating the proofs with a moderately strong solution of salt will often have the desired effect so far as reduction is concerned; and, although this treatment to some extent interferes with the subsequent action of the toning bath, and probably renders it impossible to secure the highest quality of result, it can at least be said that the colour ultimately attained can be relied upon as permanent. But this method is only available in very slight cases. Where the over-printing has been considerable, the only methods of any use are those applied after toning, and these consist, to mention only one or two examples, in submitting the proofs to the action of a weak solution of cyanide of potassium for a short time, or until the desired reduction has taken place, or to a prolonged immersion in the ordinary hypo fixing bath. The former acts probably upon both the gold and silver composing the image, and the gold, being not only present in much smaller quantity than the silver, and forming, moreover, a merely superficial layer, is acted upon or dissolved in larger proportion than the latter, with the result that the colour of the print becomes much browner, and partakes more of the unpleasant tone of one containing no gold.

There is one other method which may be mentioned, and which is applicable only to prints after fixing, whether they be toned or not. Probably for a reason we shall mention, the omission of toning previous to treatment is an advantage in this case. This plan consists in bleaching the image or converting it into chloride of silver by any of the usual methods, and subsequently redeveloping it with hydroquinone, metol, amidol, or other of the developers not prone to stain the paper or film. This, although a somewhat troublesome plan, is the most scientifically correct in principle, as, without losing the minutest detail in the high lights, the shadows can be brought to any degree of depth desired. In other words, the excessive deposit produced by the over-action of direct light can be reduced by simply arresting development at the right point.

It will be observed that the formation of the redeveloped image does not depend upon the graduated action of light upon a layer of chloride of silver of uniform thickness, but upon the total or partial reduction of such a layer, varying in thickness according to the gradation of the picture. Consequently the high lights or finest gradations, instead of being the last to appear as in the development of an ordinary positive, commence to appear simultaneously with the deepest shadows; and, as the action of the developer penetrates gradually into the film, the whole or only a portion of the silver chloride present may be reduced as seems desirable, and the action can be stopped when the image has acquired the correct strength, any unreduced chloride being removed by a second fixation.

When this process is applied to a previously toned print, there is a curiously strong tendency for the redeveloped image to revert to the same tone as the original one. It might be supposed, when, say, amidol is employed, a developer which, under ordinary circumstances, gives pure black tones, that under any circumstances the redeveloped image would be black, whatever its original colour; and, though this may be sometimes the case, the reason is not very clear, and certainly in most instances it is as we have stated, the original tone is reproduced; as it is seldom or never possible to secure a good tone, or to judge what the colour would be when reduced in cases of over-printing, it seems therefore desirable to dispense with toning altogether before treatment, and to perform that operation afterwards, when a permanent and reliable result is possible of attainment.

This is more especially so since the introduction of the practice of development of partially exposed printing-out papers, for here, as is well known, the image can be developed to any depth, of a colour exactly, or at any rate closely, resembling that produced by direct printing, and, most important of all, capable of being toned in precisely the same manner as if printed out in the usual way. Similarly, if an over-exposed print be washed and fixed without toning, bleached, and redeveloped with a solution of hydroquinone containing a large proportion of bromide, the action can be stopped at any desired stage, and the image is then, after due washing, capable of being toned in the usual toning bath along with other prints produced in the ordinary way. W. B. Bolton.

(To be continued.)

THE PHOTOGRAPHIC SALON.

There was once a king who, having satiated himself with all the pleasures at his disposal, fell to sighing for a new one. The gratification of that pampered monarch's wish could not possibly have afforded him more delight than we have experienced at the opening of the Fourth Annual Exhibition of the Photographic Salon. Great, however, as is our pleasure, we feel it difficult to say whether that particular sensation is not eclipsed by one of simple amusement. "Each thinks," said a poetess who flourished earlier in the century, "his little set the world." At this moment there are a number of gentlemen who strike us as honestly believing that the radius of the circle of photographic art is drawn from a centre which is to be found at the Dudley Gallery, Piccadilly; but the dividing line between an honest belief and a delusion is notoriously difficult to determine, and we may therefore be pardoned if, in the present case, we also shirk a task that might baffle abler persons than we pretend to be—nay, even an art critic.

It is far easier for us to explain why we are both pleased and amused that the Salon is once more with us. We are pleased, because we know that in expecting to see some good photographs we shall not be disappointed; we are amused at the trumpet blowing that has preceded the opening of the Exhibition; we are amused, by anticipation, at the more or less harmonious orchestral performances that are certain to follow it. After the lapse of three years from the establishment of the Salon, there would appear to be in the minds of certain literary members of the Linked Ring so much doubt as to whether the photographic public has yet risen to appreciate the Salon as highly as they think it should be appreciated, that recently they very laboriously endeavoured to convince their readers that the Salon Exhibition *was* devoted to the exploitation of "pictorial" photographs. As nobody, so far as we know, has lately made any allegation to the contrary, we presume that these pronouncements were designed to be so many advertisements, which would not have been printed had they not have been badly needed. There is, in fact, great danger of the Salon being taken seriously now that the fever of novelty has abated, and it becomes more and more difficult to hang or to find photographic eccentricities, which in themselves constitute so many cheaply obtained inducements to a guileless public to disgorge its shillings and sixpences for the purpose of securing a hearty laugh.

As to the amusement which we are tolerably confident awaits us in the immediate future, it is perhaps needless to say that we shall derive it from the writings of the professional art critics who, as past experience tells us, usually treat a photographic exhibition with contempt, in-

tensified by ignorance and prejudice, unless paid or cajoled to do otherwise. These gentry differ among themselves with splendid independence when writing of the Salon or any other photographic exhibition, and it is safe to say that nobody gets any profit from the *mêlée* save plain persons like ourselves, who thereby learn how far to trust to the judgment of those whose qualifications to pass one may safely be said to exist almost altogether "on trust."

But for all that, this year's Salon Exhibition is one that no photographer can visit without gain as well as pleasure. It is a magnificent display of between three and four hundred beautiful products of the lens and the dry plate. It is true that, so far as originality is concerned, about eighty per cent. of the pictures hung should have justly joined the great army of the rejected, inasmuch as we saw them, or something very like them, last year and the year before; but, as there are four walls to be covered, it would be churlish to grudge the committee of the Salon whatever "padding" was found necessary in order to make the display "pan out" to the money's worth. Thus they temporarily serve a useful purpose, and, having done so, will, like their predecessors, pass into oblivion, as to the certainty of which there is no doubt at all.

There are, we think, two respects in which this Exhibition may be allowed to rank as the best of the series. The portraits are better than hitherto; and the "figure" studies, to use an intelligible if unsatisfactory term, are extraordinarily fine. What is here shown in these two branches of work would be difficult to surpass, and is well worth careful study. The landscapes, the river scapes, and the seascapes, the cattle pieces, &c., are pretty much what we have seen before; the nude is not conspicuous, and is consequently inoffensive; the frames are in good taste, and the effect on our minds, after a careful and lengthened study of the Exhibition, is, that collectively it is possibly the finest show of (pictorial) photographs so far got together. We probably said something like this last year, and now, as then, the admission is not made without a feeling of melancholy that, in two or three months' time, probably not a score of these photographs will be remembered by anybody but their producers. In previous years a feature of the Salon has been the inclusion of a number of works of which, as the popular phrase goes, you could not make head or tail; formless blurs, out-of-focus and foggy smudges, that provoked ridicule and pity. Well, ridicule has once more killed, and the Salon this year hardly contains a single exhibit of a pronouncedly "Salonic" character.

The prominence and the number of foreign exhibitors gives the Exhibition a quite international character, and it is with the work of one or two of these same foreigners that we ourselves are most pleased, and to which our note book contains proportionately more references than to that of native photographers. The unreadiness of the catalogue and the confusion of names, numbers, and titles at the time of our visit obliges us to give on this occasion a somewhat shorter notice to the pictures than hitherto, and it is therefore impossible for us to do more than take a brief glance at what struck us as the leading features of the display.

The little figure studies of Le Bègue that hang at the near left angle of the gallery as one enters are truly delightful in ease and grace of posing, and in delicacy of lighting. His *Etude du Nu*, a nude woman turned from the spectator, with outstretched hands against a screen, is almost faultless in modelling. *L'Attente* and *Etude Plein Air*, the one a fully draped female figure in the open, with her hand to her face in an attitude of expectation, the other a partly draped study, are good examples of this worker's felicity in choosing simple themes and successfully treating them.

Mr. Davison has enabled us this year to understand him somewhat at last. His *Rain, Steam, and Iron*, a glimpse of, if we mistake not, Hungerford Bridge in a rain storm, looking north, is, if very "impressionistic," realistic enough to be convincing and understandable. It is a "Whistlerian" effort, and will probably delight Mr. Davison's admirers. *O'er the Lea* shows Mr. Davison in another mood. It is a really beautiful study of cattle passing leisurely through an open gate, a lovely stretch of country upland forming the background. The effect is soft, unforced, and natural. *Decayed Staithe*, a bold waterside view, and *In an Osier Country*, in a somewhat similar style of work, and in a yellowish-brown tone, apparently on canvas, are examples of Mr. Davison's "scene-painting" like manner.

We note a little view called *A Telegraph Pole* by Mr. Lionel C. Bennett. The pole stands by the side of a reed-fringed river, and it does not appear to have moved during the exposure. Our Correspondence columns are open to Mr. Bennett if he cares to explain why he hath done this thing. *The Mall*, by Mr. Calland, is a pleasing example of this gentleman's skill in securing happy effects of light and shade in an ordinary London thoroughfare, as witness his last year's *Brompton Road*. Dr. Henneberg shows a beautiful view, the composition of which we very much admired It depicts a *Village in Pomerania*, a small group of old houses embosomed in trees. Brown carbon appears to be the printing medium. and the picture is one of the most pleasing, because the most natural, bits of landscape hung here.

There are several specimens of "bichromated gum" printing that do not flatter the process, the effects obtained being coarse, crude, and wanting in delicacy, and we pass on to remind Mr. L. Cohen that, when he next photographs a young person showing her teeth, it is ungallant to make them appear larger than their natural size. His *Study of a Head* sins in this respect. We note, for the first time, the name of Mr. W. A. Locks at the Salon. He shows a very clever piece of work, *Daughters of the Soil*, depicting two (? gipsy) women in a field seated by a kettle suspended from a tripod over a fire. It is a clever, glowing bit of work, the grouping and figures being lifelike, the landscape real-looking and harmonious. We hope Mr. Locks will give us more of this kind of work. Mr. W. Dawes shows a crisp and brightly rendered study of a thistle bank, but Mr. Dawes, who is far from a novice at pictorial photography, should endeavour to cultivate a little originality. This is one of Mr. Davison's cast-off subjects. Watzek's large and effective imitation crayon, *Baumstudie*, will probably please many who like this photographer's singularly delicate work. Of Mr. Maskell's three portraits: Mr. Corbould, Mr. Davison (the best likeness of "G. D." that we have seen, the expression and attitude being extremely lifelike) we prefer the *Dutch Girl*, which, with all its apparent simplicity of style, is really a powerful bit of work. We are sadly disappointed with Mr. Edgar Lee's *Marshy Moorland*, a red-toned bit of landscape which betrays no evidence of being anything but just a hap-hazard photograph of an ordinary view.

Mr. E. R. Ashton's Eastern studies show all his old care and skill, but a photographer of Mr. Ashton's undoubted powers should make up his mind to try his hand on subjects other than those ready to hand. Much the same remark may be applied to Mr. Bhedwar's series *The Renunciation*, which, despite its wonderful photographic excellence will probably excite little interest here. The series tells of the gradual progress of the aspirant after spiritual perfection, and the *dramatis personæ* are drawn from the ranks of those Indian religious with whom Mr. Bhedwar has already several times made us acquainted.

The Village Choir is the name given by Mr. John E. Dumont to a photograph of two women and two men singing, with diversified expressions. It is an interesting and comedy-like study, and only narrowly misses being a very great success.

Of Mr. H. P. Robinson's contributions we much prefer *Returning to the Fold*. In the glow of darkening evening a flock of sheep is receding towards the distance. To our mind the effect of motion in the flock is well suggested, and, though the subject may not present as much difficulty as some of the others Mr. Robinson has taken in hand, we are more pleased with its sentiment and its effects. Have the Robinsonian female models all gone and got married, or struck for higher pay, that he thus entirely abandons them? Mr. Robinson's other pictures include some deftly executed seascapes, one, *A Breeze of Morning Moves*, being an attempt—and a very successful one—to depict a Scotch mist clearing off as a breeze approaches. But somehow we sigh as we look back to the vitality, the humanness, the *aplomb* of *Carolling*.

Mr. Horsley Hinton has accomplished the very difficult task of beating his last year's work. It is of the same style, but Mr. Hinton has thrown off the fetters that bound his selective powers, and this year gives them greater scope. Sameness of subject and style, that we noted in Mr. Hinton's work for years, no longer characterises it. Take, for instance, his *Requiem*—an old boat by a lonely river bank. It is a simple—you might almost say a commonplace—theme, and yet Mr. Hinton has imparted to his view an almost appreciable atmosphere of quiet and melancholy. *Sunshine and Rain*, another of his works, is a wonderfully effective rendering of rain beating down on a partly sunlit landscape. We should be surprised if this is not voted Mr. Hinton's best. *Tide-bereft*, a characteristic study of a dried-up waterway, is another admirable piece of work. Mr. Hinton has acquired a mastery of the platinum process, and one of his pictures has been cleverly toned so as resemble brown carbon.

We must compliment Mr. C. L. Emmanuel on the admirable transparency and light and shade of his little view, *The Terrace at Richmond*. Mr. J. Craig Annan, as usual, plays a strong hand. His *Sisters* (portraits of two ladies) is really a triumph of that art which conceals art, the poses being graceful, free, lifelike, and uncommon. A bit of work of this quality and power tells a photographer more in ten minutes' contemplation than libraries of art writings or any number of debates. But then Mr. Annan is a master craftsman to his finger tips, and, besides thinking

out his subjects, knows how to print and frame them. *The Church or the World* is his most ambitious attempt. The flower-decked girl on the pale steed, that is led by the black-cloaked dimly seen nuns, looks out to us, and asks, as it were, in her own mind that most momentous question, Which shall it be? She yearns perhaps for a life of piety and contemplation, but—oh, the price to be paid, and the sacrifice to be made! Mr. Annan's other subjects include an interior, *The Marble-cutter*, and a charming Venetian scene. His versatility is very great.

To our taste, and in our opinion, the work of M. Ch. Puyo is not far short of being the soundest and the cleverest in the Exhibition. Note the fine, the true effect of lamp light in the sleeping room, *Le Coucheur;* the astonishing force and naturalness of the laughing expression on the faces of the two women in *Gaieté!* Not merely is M. Puyo a master of delineating expression by means of photography, but his power of posing and grouping figures is assuredly the greatest we have met; his pictures are always faultlessly illuminated, his accessorial details correct to the minutest degree. Then what exquisite prints he gives us by the much-discussed Artigue process! To any photographer who desires to inspect some of the finest figure studies in ordinary rooms, M. Puyo's exhibits here, of which we have only mentioned two, should be invaluable as object-lessons.

M. Demachy sends some refined and thoughtful head studies on bichromated gum paper. We have only space to compliment Mr. Craigie, Mr. Hollyer, Mr. Van der Weyde, and Mr. W. Crooke on some very fine portrait work, differing in style and treatment, but all worth studying.

This short notice, the brevity and incompleteness of which is our misfortune and not our fault, by no means does justice to the Salon Exhibition. We may—and indeed we should like to—return it; but in the mean while we can honestly recommend our readers to go and inspect it. After all said and done, the Exhibition, like the play, is "the thing;" and, however much our friends of the Linked Ring may amuse or confuse us with their art writings and theories, they deserve the amplest recognition of the beauty and the variety of the collection of photographs they have just thrown open to the public.

EXHIBITIONS AND JUDGES.

Every year, as surely as September itself comes round, we begin to see in the press expressions of dissatisfaction with the awards made by the Judges at the Exhibition, and comments on the unsuitability of the gentleman elected to the office. A.D. 1896 appears to be an exception to the rule however, as the criticism on this occasion has been made first, leaving the Judges to act up to it or not afterwards, as they may feel disposed. That this is the case can be seen by reference to the last issue of The British Journal of Photography, in which "Cosmos" deprecates the employment of "artists" and Mr. Maskell that of "painters" as Judges, the two terms being used as if they were synonymous by the two writers.

It is just in this fact that the gist of the whole matter is to be found, and the use of the term "artist" as applying chiefly if not exclusively to painters, might be made the text of an instructive, if humiliating, lesson to photographers. To "Cosmos's" criticism no possible exception can be taken. His objection is based on the experimental ground that they have been tried before and found wanting, and on the experience of past years he is not in favour of their employment at the same task again. This is, of course, a matter of opinion, but still of opinion formed by observation. Another writer, however, is opposed to the judgment of painters on what would be more correctly described as theoretical grounds, and gives at some length what may, I suppose, be regarded, bearing in mind that it proceeds from a high official of the body, the Linked Ring's aspect towards the question.

Like that of many theorisers, Mr. Maskell's position is hopelessly at variance with his published views on a kindred subject. When his object is to decry the sharply focussed, glossy-surfaced, technically perfect print, and to exalt the class of photograph which he appears to admire, we find him persistingly claiming that the technical details of photography should be entirely ignored and left out of consideration altogether. Over and over again, with every conceivable method of expression, the pages of the photographic press have given publicity to the demand of Mr. Maskell, and of those who for one reason or another act with him, that a photograph should be regarded simply as a work of art. That the ability to produce a photograph pleasing to some extent as a work of art may exist side by side with a complete incapacity to master the comparatively easy technical details, we have annual opportunities of seeing in more places than one, and this fact may be taken as supporting their contention. But it is amusing, to say the least, to find that, when it becomes advisable to denounce the employment of painters as Judges, the same writers labour to show the extreme importance of a knowledge of technical photography in a Judge, and that Mr. Maskell has occupied a column and a half of the Journal in advocating the importance of technique. If a knowledge of photographic manipulation is so important in a Judge, how much more so must it be to those who produce the works judged; and, on the strength of his complete conversion to the views held by ninety-nine hundredths of the better class of photographers, I cannot refrain from offering him my heartiest congratulations.

The difficulty under which photographers who are anxious to have their pictures judged as works of art have always laboured has been caused by the absence from their ranks of men who have undergone anything which may be compared with the training of the painter. With exceptions which can be counted on the fingers of one's hand, the photographer's training in this respect has been confined within limits which the man whose life work is painting passed while in the teens. Judged even by the South Kensington standard, I have great doubt whether the ranks of those who use photography as a graphic art could produce a couple of dozen men whose training would admit of the authorities granting an elementary art teacher's certificate. The reason for this is not very far to seek, and does not lie in the absence of artistic ability in those who take up photography, but is rather to be found in the limitations of photography itself. These limitations soon drive the artist to the pencil and the brush, leaving to photography those to whom the lack of time, opportunity, or ability, compel to be satisfied with the camera and printing frame.

It is with no desire to depreciate photography and photographers that I write as I do, and I should be the first to acknowledge Mr. Maskell's boldness in claiming the high ground he does for photography as an art; but the very extravagance of the claim can only damage the cause by exciting the feeling that, where the main claim is disallowed, the minor claims must go also, and no good can come from articles in which the "pictorial photographer" is encouraged to think still more lightly of himself than he does already. Photography may be regarded by some as a short cut to the studio, doing away with the necessity for anything more than the possession of a certain amount of uncultivated taste; but painters, the general public, and nearly all photographers (including "Cosmos"), give an unmistakable verdict by using the word "artist" without qualification as implying painter.

One of the most remarkable features in connexion with photography is the extreme rapidity with which the necessary ability can be picked up; and by turning over the pictorial supplements to the *Amateur Photographer*, which used to appear some years ago, it can be seen that the art training of some of those who pose as authorities is of the most recent and sudden nature. It is to the fact that, with two or three exceptions, the loudest "professors of the system," to use Mr. Maskell's phrase, are the production of the last five or six years, that the poor opinion of the work of ten and twenty years is due. Thus, I notice a writer in a contemporary states that till three or four years ago all exhibitions were little else than exhibitions of technical skill, ignorant apparently that before this time there had been exhibitors named Robinson, Blanchard, Rejlander, Salomon, and many others whose work displayed at the very least as much artistic ability as any now shown in this country. Of course, the prints of ten and twenty years ago look crude and "technical" now, the fashion has changed. But to suggest that these workers and many others exhibited their work simply as technical or topographical photographs, and that their aims were not as high as those of the best present-day workers, is to indicate blindness of a very aggravated type. Photography as an art dates back, as Mr. Maskell has pointed out, to 1845 at the least; and to conclude that because *Bringing Home the May*, for example, is not in keeping with modern ideas, its producer aimed simply at a good technical result, is as erroneous as to imagine that our grandmothers did not dress for effect because they wore crinolines and coalscuttle bonnets. Photographers have always been divided in interest, some inclining towards the manipulatory details, others towards the artistic side. Just as we see now, on one hand, Mr. Robinson complaining that the Photographic Society is too exclusively technical, while Mr. Horsley Hinton, on the other, denounces it for paying too much attention to artistic work, we find in the past similar workers endeavouring to monopolise the attention of the Society to one or other side of photography. The times change, but human nature is human nature still, and a photographic exhibition in 1886 was not so unlike a photographic exhibition in 1896 as many people seem to imagine.

R. Child Bayley.

JUDGING PHOTOGRAPHS.

The very interesting and opportune communication by Mr. Maskell on the subject of *Painters as Judges at Photographic Exhibitions* (see The British Journal of Photography, September 18, 1896, p. 597) is worthy of careful consideration. The subject in question is one of far-reaching importance to all photographers who aim at producing pictorial work, be they disciples of the sharp-all-over, the fuzzy, or any other method of expression. As Mr. Maskell very properly points out, photography "has had time to acquire a status of its own," and he also instances the unfitness of seeking an engineer's opinion in electric matters. But something further may be said upon this topic. The same conclusion may be reached by a somewhat different though partly parallel course.

In the first place, it may be taken for granted as admitted generally, almost universally, among present-day artists, be they architects, sculptors, engravers, etchers, &c., that no thinker or writer has so accurately formulated the great *art principles* as Mr. Ruskin. Not only is his *teaching* very generally accepted—with perhaps here and there allowance made for strong personal predilection—but its effect is being constantly seen in the best *work* of our foremost workers, and in no department more than in that of modern painting.

Now, Mr. Ruskin has laid it down again and again that, while there are certain underlying principles common to all forms of art, yet each has its own special excellences and limitations; that, when work by one art method resembles work by another method, it is a symptom of weakness, showing that the virtues of the material are not known or appreciated, or properly used. The rule of art is "I can, therefore I ought." Furthermore, he says that an art is bare if it does not properly employ the special and distinctive qualities of its materials and methods. For example, methods and results which in drawing are good and highly commendable may be bad and to be condemned in painting. In the same way the water-colour drawing which aims to imitate oil-colour painting is based on wrong principles. In a work the best art is that which has the greatest knowledge of and command over its own peculiar excellences, possibilities, and limitations.

If, now, photographers seek the opinion and decision of any other art workers, *e.g.* architects, sculptors, painters, etchers, &c., who have not practical knowledge of photographic possibilities, methods, and limitation, it would seem *primâ facie* probable, to a degree practically amounting to certainty, that such opinion would be quite unreliable. The opinion would not necessarily be wrong, but it would only be right by chance, and not by knowledge. For how can a man judge of things concerning which he is ignorant?

Practical knowledge is of the essence of adjudication. The real critic is he who makes a *κρίσις*, *i.e.*, a separation or discrimination, and not, as is too commonly supposed, one whose business it is to pronounce *κατάκρισις*, a condemnation. Without knowledge, it is not judgment, but opinion, which very probably springs from guesswork and prejudice. In this connexion it may be well to recall the well-known words of Quilter: "I have given some years of my life to the study of pictures and to the technical processes of art, for experience has convinced me that without practical power of drawing and painting no real knowledge of pictures is possible."

Again, if a man who is a painter only (*i.e.*, without practical knowledge of photographic methods) is duly qualified to judge photographs, it should follow that a photographer who knows nothing of the practical painter should be a competent judge of painting. It would be interesting to know the painter's views upon this aspect of the question.

To return, however, to our starting point, viz., that every method has certain properties, virtues, and limitations, which are essential parts of its existence. For example, the sculptor deals with things on the round, in relief and form is of the essence of his method. Colour would degrade, confuse, and detract from this. Hence attempts at coloured sculpture have always been shunned as base and false methods. Painting, on the other hand, deals with things in the flat by an admittedly obvious optical illusion, but here colour is of its essence, and all else must contribute and not rival the nobility of colour. Similarly the etcher, working with a point giving a line, sacrifices everything to grace and expression in his lines. He stands or falls, as the vitality of his line is or is not.

Coming now to photography, it is not easy to find any *one* word which compresses its unique and unrivalled power of recording the existent, but every practical photographer feels he has a power of presenting what is before him much or little, sharp or soft, which no other at present known method possesses.

As Mr. Maskell says, "It has had time to acquire a status of its own." But we may go farther, and say that the best work of the more advanced pictorial photographers has already shown—examples may now be seen on our Exhibition walls—that not only has it acquired a status of its own, but, further, these results show that modern triumphs have placed in the photographer's hands possibilities which are quite out of the reach of any form of draughtsmanship. Thus photography has its own canons of art, range, and practice.

Photographers generally have in the past made a very serious mistake in endeavouring to make their work always accord with the painter's and etcher's dicta. To a considerable extent this has delayed the exploitation of photography in the pictorial direction. Not only is there no inherent necessity why photographers should, as heretofore, limit themselves to feeble imitations of engravings or drawings, but such a self-imposed limitation is contrary to any logical sequence.

We English folk are essentially, and as a majority, characteristically conservative. What hitherto has been the standard or limit is not easy to displace. This attitude may be safe, and often is commendable, but, when carried to excess, is very apt to strangle originality, and discourage the growth of that most desirable quality, viz., expression of personal feeling. Not that any oddity or extravagance should be admitted as original merely because it is something different from previous practice or results, but what seems especially called for at this present juncture is a more liberal attitude of mind, such as leaves one absolutely free to accept or reject a result entirely on its own merits, without staying to inquire how it was or was not produced, or how it agrees with previous standards of photography. In a word, what we need is that photographs should be examined as photography, and not as the best imitation we can make of something else.

Etchers, sketchers in black and white, and others, have scoffingly pointed to certain examples as palpable imitations of methods other than photographic. But, in reply, two things may be said: Firstly, if the photographic worker *only* aimed at producing an imitation, he is debasing his art method; but, secondly, that a platinotype worker should produce something very like an engraving, or a pigment gelatine print should resemble a wash drawing, does not *primâ facie* prove that the photographic workers were aiming at imitation, and nothing more. The fact that any worker was the first to produce a certain result does not debar every one else from producing a similar result in that or in any other way, provided the result be satisfactory when done.

The early Assyrian who scraped grooves on wet clay, or the prehistoric gentleman who scratched on a bit of horn an impressionistic sketch of the mammoth, do not debar the wood or metal engraver from cutting their lines. The silversmith, using a brush to polish his goods, does not proclaim against the bootblack producing a polish in a similar way, nor is there any reason in the painter objecting to others using a brush, or producing results similar, and not always pictorially inferior, to his own. Any stick will serve with which to beat a dog, and this dog-in-the-manger cry of "You are trying to imitate us!" is unhappily one which does not leave the photographer entirely free from blame. He has unfortunately thought that the painter's opinions, subjects, and methods were final, and that the nearer he could approach them the better were his chances of securing a comfortable corner in the artistic Walhalla. But the numerous recent successful examples of our foremost workers—English and foreign—have abundantly shown that we need no condescending patronage at the hands of painters, etchers, or others. We have a position and an art of our own, and it is giving ourselves away when we call in others, who know nothing of our practices and possibilities, to tell us what is good or bad.

We are, of course, always glad to know what others think of our results, of the impressions our work gives them; but their opinion, as non-photographers, is only an opinion, and not a judgment. It is exactly of the same intrinsic value to us that our opinion, as photographers only, of their painting is to them.

Every true artist works, first, for himself, as an expression of his own likes and dislikes, feelings, fancies, and ideals; secondly, for those who follow methods the same or very closely allied to his own; thirdly, to all who have artistic knowledge and culture apart from their method of expression; and, consciously or unconsciously, he feels within himself the sentiment which in Yorkshire we express aptly, if not elegantly, in the phrase, "Let every tub stand on its own bottom." F. C. Lambert.

ENAMELLING GELATINO-CHLORIDE PRINTS.

In the general practice of photography the best average of good results in the different processes is obtained by adhering as faithfully as possible to the instructions supplied by the manufacturers. After conscientiously practising these, then individual departures can be indulged in, perhaps more suitable to the worker's special requirements.

It often happens, however, that the maker's directions are of a meagre description, too much being taken for granted. This is apparent in most of the detailed hints issued by manufacturers in reference to the enamelling of gelatine prints. The subject is variously summed up to the effect that a highly glazed surface can be obtained in the usual way by squeegeeing the print on glass, &c. The many little points necessary to success are not entered into, and, as a rule, an amount of unnecessary waste is encountered before the worker settles down into a regular groove. There are many modes, but one will be sufficient for the present.

The absolute certainty of prints, in large quantities, being made to strip from off their polished surfaces, free from specks or blemishes, is required before orders to any extent can be undertaken. A glance at numerous photographers' show-cases and windows reveals at times the erratic nature of some of the modes adopted. Enamelling has everywhere to some extent been attempted, but not always with regularly brilliant results. A tell-tale large print here and there left displayed on the glass support betrays the nervous reluctance to strip it off, lest it should stick like its unfortunate predecessors. This unreliability has in a measure compelled many to abandon enamelling altogether. The whole process has become so distasteful that they completely discard, and then abuse it roundly, as not artistic. The easily worked matt surface is glorified and pushed upon the customer. Personally I infinitely prefer matt surface to enamelled, but a section of the public demand the latter and should be more liberally catered for. The following hints will be found in practice to work well: Attend to the manufacturer's formulæ in washing, toning, and fixing. After the preliminary washings it is advisable to use a stronger alum solution than usually recommended, and also to leave the prints in it a longer time—say double. This will better ensure the hardening of the gelatine, which simplifies matters afterwards. After a thorough washing, make up the toning bath fairly strong, bearing in mind that, should the toning drag, the evil of softening the gelatine commences by a prolonged action of the sulphocyanide of ammonium.

When toning and fixing are finished, the prints should be washed as well and as quickly as possible, certainly not longer than two hours. A prolonged washing softens the gelatine and completely ruins it for enamelling. After washing, drain and spread the prints face outwards to dry on sheets of paper or linen in a room free from dust. A good plan is to leave them all night, and by the morning they ought to be ready. The prints can, of course, be squeegeed straight from the washing water with excellent results; but, if there be any tendency to over-softening of the gelatine, with subsequent sticking to the glass, the plan recommended of drying hard will be beneficial. Various substances have been suggested and manufactured for squeegeeing upon, but the best, undoubtedly, is glass. It must be absolutely free from scratches or blemishes, have a highly polished surface, and be scrupulously clean.

The glass used by makers of dry plates is now of a more superior kind than formerly, consequently waste negatives may be utilised for this purpose.

A most effective mode of removing the film and cleaning is as follows:—

Put into a dish a pound of ordinary washing soda, and dissolve it in two or three pints of boiling water. Place the glasses in one by one, the films all one way, say downwards. If the films are face to face, they will stick and become troublesome. Leave in the warm solution for an hour or so; the films will then be found quite soft and readily removed. Wash well and then place the glasses into a fresh dish of water, say a quart or two, with the addition of an ounce of strong ammonia. Leave steeping a while, and finally rinse well under the tap. After they are thoroughly dried make a soft flannel pad, dab it into powdered French chalk, and well rub both sides of the glasses. At this stage carefully reject any blemished glasses. After a sufficient quantity is piled, get an old silk handkerchief, or other soft material, and carefully clean off all the chalk. It is imperative that every particle be removed, for, if any is allowed to remain, an ugly smear will appear in the finished print. It is advisable to chalk and clean both sides; there is then no fear of an assistant using the wrong side.

A good plan is to have a distinctive mark, say with black varnish, which would save the double labour.

Carefully select the best polished surface, and stack ready for squeegeeing. For this, place the prints, one by one, into a dish of clean water; in two or three minutes they will be sufficiently moist to proceed. Rinse the glass under the tap, or in the dish; take the wet print and place it on, face downwards; slightly drain, and gently use a piece of soft thin indiarubber cloth or flannel to the back of print, rubbing out the excess of water, and dispersing air bells. Then spread out to dry. This should proceed evenly, and not too quickly. Bear in mind the moistened gelatine will run and adhere to the glass if at this stage it is placed too near a fire.

Use the same judgment in drying as with a gelatine negative, and all will go right. When dry, pile them up ready for mounting the backing papers.

It is important to procure a good sample of backing, for with the right kind the prints will strip off regularly and with certainty. It should be stronger than ordinary note paper. Several dealers make a speciality of it in cut sizes under the name of ivory backing. This will be found convenient to use.

For mounting, use freshly made starch. Pile up the backing papers, and, with a broad brush, paste them well, being as careful to avoid lumps as in ordinary mounting. Place the papers on backs of prints on glasses, and rub well down.

Spread out to dry, and, if in a moderately warm room or in the outside air, they will soon be ready for stripping. They dry very well in the open when a good current of air is about. A little experience will enable you to judge with certainty when they are safely ready, and, with the aid of a knife at edge of prints to start the stripping, the whole batch can be rapidly and successfully taken off. As a matter of every-day work, there should be less waste with enamelling than with burnishing. When a print is spoiled by the burnisher it is irretrievably ruined at the final stage, which means the loss of mount as well; whereas, with enamelling, a spoilt print can be, as a rule, restored by reimmersing in water, removing the blemish, and re-squeegeeing.

The trimming is easily effected, but the mounting has proved a pitfall to many. Unless a proper mode is adopted, the superior enamelled surface is dulled, and the result rendered most objectionable.

The backing is used to prevent the mountant from permeating the print and dulling its surface, and the mountant itself is prepared with the same purpose in view.

Melt some ordinary glue with as little water as possible, the less the better. When fully melted, and while hot, add methylated spirit until the mixture is of the right consistency for use, which will be found about as thin as golden syrup. The addition of glycerine is an improvement—about half an ounce to a quarter of a pound of glue. Do not use the mountant too hot, and there will be no fear of its penetrating the backing.

In mounting take the backed print in left hand, and with a thin hog's-hair brush glue round the edges to the extent of a quarter of an inch. Brush it on lightly and in such a manner that none will be squeezed out when the picture is under pressure. Place the glued print on mount, cover with piece of tissue paper, and pile face downwards one on the other, using a flat iron or other convenient weight.

THOMAS M. LAWS.

OBTAINING PHOTOGRAPHS IN RELIEF IN GOLD, SILVER, AND OTHER MATERIALS.

MESSRS. HILL & BARRATT are the patentees of this invention which relates to the making of photographs in true relief, either in plaster or other plastic material, or in metal by electro-depositing.

The process in the first stage depends on the well-known action of light on bichromated gelatine, in rendering it insoluble and incapable of absorbing water, and is to obtain a simple method of obtaining higher relief, and also, in the case of portraiture, to correct the false modelling which in most cases is present.

In the case of side-lit portraits with black backgrounds no preparation of the negative is necessary, nor from copies of wash drawings where the background is the darkest part.

In the case of an ordinary portrait false modelling may occur, as light in this process takes more note of colour than form, for instance, a portrait in which the hair is dark; the modelling of the face would be rendered correctly, but the hair would appear in the relief to sink into the head, and the background, if light in colour, would not recede sufficiently to throw the head into high relief.

To overcome this difficulty the background is painted on a print from the negative, with black pigment, and the lights on the hair accentuated with a white pigment. An alternative is to make a thin negative, intensify with uranium, and reduce where necessary with strong ammonia.

The method we prefer to work is to coat a piece of plate glass (which has been well rubbed with talc,) with gelatine, to which may be added proportions of sugar and citric acid to render the gelatine flexible; this is dried gradually to prevent reticulation. The mixture when dry is stripped from the glass, and is then sensitised in a solution of bichromate of potash (preferably two per cent.).

It is then exposed to the action of light under the negative, the gelatine being flexible can be readily examined to watch the progress of printing.

When sufficiently printed it is firmly cemented to glass, with an adhesive which swells in the same proportion as the gelatine. We prefer the use of isinglass dissolved in weak acetic acid, to which is added a small proportion of celluloid dissolved in amyl-acetate.

The plate thus formed is soaked in water, and the gelatine will swell where not acted on by light, and a photograph in very low relief in gelatine is obtained.

When all the bichromate is soaked out, the gelatine relief is plunged into weak acid, preferably citric acid, in the proportion of one part of citric acid to six of water by weight, or citric acid may be well rubbed into the surface, and is then transferred to cold water.

The gelatine not being able to swell laterally, owing to its being cemented to glass, expands vertically, but only when still absorbent to water; when the gelatine has been acted on by the light, the acid will

not penetrate. The increase by this treatment is from two to four times the relief originally gained.

From the swollen gelatine thus obtained, plaster casts may be taken, or copper may be deposited direct if the surface is rendered conductive by the use of any of the well-known agents, such as bisulphide of carbon and phosphorus followed by nitrate of silver solution.

The patentees claim:—

I. The correction of the print or negative as hereinbefore described, or by retouching on the negative.

II. The vertical expansion of a gelatine relief, by means of an acid, preferably citric.

III. Photographs in metal, or plastic material from gelatine reliefs.

THE SOLARISATION PROBLEM.

[Translated from the *Photographisches Archiv.*]

Mr. F. Krohn* doubts if a membrane of metallic silver prevents, in a measure, the penetration of the developer to the back of the film, as I have supposed. Further, he does not believe that the whiteness visible between the silver and the glass is bromide of silver. The first of these phenomena, unfortunately, cannot be so easily proved by drip experiments (see *Photographisches Archiv*, 1896, page 228; *Naturw. Wochenschr.*, 1896, page 353), like the properties of other membranous deposits. For, in the first place, we are not dealing with a jelly, but with a dry gelatine film, when the plate is immersed in the developer. The diffusion processes in such are quite different from those when the film is saturated. Consequently, I am unable at present to do more than draw conclusions from what happens in developing a dry plate as to the truth or untruth of my hypothesis.

In the following I will describe a further observation concerning the appearance of the back of a negative.

A bromide dry plate, prepared for photo-mechanical purposes, with a somewhat thick coating of a slightly ripened emulsion, was exposed in the camera through the glass. Upon development with a normal hydroquinone developer, the picture appeared quickly in full strength on the glass side. The front of the film, on the contrary, did not blacken, even with more prolonged development. In this case the image was of no great depth, because the bromide of silver was reduced only on the surface next the glass. The light had not sufficiently penetrated the film.

A second plate was given a rather longer, and therefore normal, exposure, and then treated with the same developer. The light having penetrated sufficiently, the image appeared on the front as well as on the back. By transmitted light the image was exceptionally vigorous.

In over-exposure an image appears first on the surface. It is comparatively hard. After further development it passes through the film. From the glass side it has a flat to veiled appearance.

With still more exposure, and especially if treated with a strong developer, the negative does not penetrate the film to the back. It may appear there in the nature of a positive.

Further, *the penetration of light* through a coating of emulsion also plays an important part. Transparent chloride plates are traversed by it more quickly than well-ripened gelatino-bromide plates. The opacity has already been used to avoid reflection from the glass (halation). An addition of iodide of silver, for instance, has been utilised. Eder arrived at the conclusion "that the thinner image due to iodide of silver on a gelatine-bromide plate is partly ascribable to the non-actinic colour of the former, which hinders the penetration of light." Or the penetration of light may be counteracted, for the above purpose, by the addition of dyes to the emulsion, as recommended by Eder and Vidal. The former preferred chinoline yellow, the latter picric acid and the picric salts. But it would be going too far to ascribe to this circumstance alone the greater density given by gelatino-chloride and unripe gelatino-bromide, as compared with ripened gelatino-bromide equally rich in silver. The depth to which light can penetrate is to be considered in explaining the effect of Sandell plates. Moreover, as I have shown above, all thickly coated emulsions are capable of yielding, on the one hand, flat, and on the other hand vigorous, images.

But all the phenomena cannot be attributed to the penetration of rays of light. *For the present I have no other explanation to offer for them than the protection of the deeper layers from the developer by a membrane of metallic silver.*

Whether this silver membrane also hinders fixation, or, in other words, whether the whiteness lying between the metallic silver and the glass is unreduced bromide of silver, is another question. The second objection made by Krohn is opposed to this, and I must admit that I was unable to remove the whiteness when *subsequently* stripping the film from its support. I will, however, investigate this matter further.

What can this whiteness be? Gaedicke wrote to me recently, that he had often examined this whiteness and formerly had attributed it to a modification of the metallic silver. Krohn appears to be of the same opinion. This theory would consequently read as follows, that after too much exposure another form of metallic silver is produced in development.

But why is this always formed only between the black, ordinary silver and the glass? Why not, for example, on the surface of the film if the plate is exposed through the back?

Perhaps future investigation may lead to a totally different explanation. But for the present I do not know of any other, although different facts cannot be brought into harmony with it.

That, besides these diffusion processes, purely chemical may also cause the veiling and ultimately solarisation, I will not dispute. Solarisation of printing-out chloride papers can, probably, be caused by the latter only. I only wished to draw attention to the fact, that the phenomena of diffusion should be borne in mind in photographic processes, more than has hitherto been the case.

Physics, in the apparently pure chemical processes of photography, must receive as much attention as in the processes going forward in living beings. Only because the problems were considered too exclusively from the chemical standpoint was it impossible to arrive at a solution sooner.

If my physical theory of solarisation was rather too one-sided in the opposite direction, this was principally to shew, for once, how great a part may be ascribed to purely physical processes. R. Ed. Liesegang.

* See The British Journal of Photography, August 28, 1896, page 554.

BYROM'S IMPROVEMENTS IN GRAINED SCREEN PLATES FOR PHOTO-MECHANICAL PROCESS WORK.

Mr. John Byrom states that his improvements consist in making a screen or grating which shall be indestructible, and, at the same time, have a clear plane glass surface at a lower level than the opaque lines or dots.

In making a screen under one modification, a glass plate is first coated with varnish or with printers' ink, or other suitable substance, and afterwards dusted with enamel colour, or such colour may be mixed with the varnish or ink, or other suitable substance when applied.

The plate is then ruled, and afterwards fired in a kiln to fix the colour in the lines or dots.

"If desired, the plate, after being coated with enamel colour, may be fired before being ruled, and in this case, in order to form the lines or dots, I coat the fired plate with a suitable resist, then rule through the said resist to the enamel colour, and afterwards etch through the enamel colour to the plane glass. By this means a plate is produced of which the grained surface is not liable to be damaged by rough or careless usage.

"I do not confine myself to ruling the plate as above described, as various methods of producing the screening or graining may be employed as found convenient, as, for instance, an impression may be taken from a ruled or etched metal plate, or from a reticulated gelatine film or collotype tissue, and such impression applied to the plate, which is then dusted with enamel colour and fired as above described; or I may transfer direct from the gelatine film or collotype tissue, or I may apply the resist above the fired enamel colour in the form of a powder, and preferably in a resin dusting box, so as to obtain a grain, afterwards heating the plate to melt the dust, and fix it, and then etch through to the clear glass.

"Or the enamel colour may be dusted on to the varnished plate so lightly as to form a grain, and thus dispense with ruling or transferring."

Mr. Byrom claims: A screen plate or grating, the screening or graining of which is formed of enamel colour fixed and burned into the glass by firing in a kiln.

RETOUCHING MEDIA.

To the portrait photographer the question of a reliable retouching medium is an important one. For, in spite of all the denunciations of artists and scientific photographers, retouching is more necessary than ever, and as long as human nature is human nature retouching will remain an essential part of every portrait photographer's daily work. Therefore, it is desirable that each should find for himself a medium upon which he can depend. As I make a medium which is put upon the market by a London dealer, I cannot give a formula as desired by your correspondent, but I can point out some differences in various kinds offered for sale. One make which I used for several years, and which appears typical of many, consists apparently of a hard gum dissolved in oil of lavender and turpentine, with the addition of some slow drying substance, which keeps the surface of the negative in a sticky condition for a day or two. My experience of such a medium was, that when the bottle was first opened the medium was too thin, and it was difficult to get sufficient work upon the negative. When about a week old the medium seemed at its best and then soon deteriorated, becoming what painters call "fat," giving a greasy film difficult to work upon, and in a week or two the remainder of the medium was useless. Another disadvantage it possessed was that the negative had to stand at least an hour after the application of the medium before work could be commenced, and it seemed to be in its best condition if applied to the negative overnight.

Still another disadvantage was that it dried so hard that no more work could be put upon it, if left for a day or two. This was very inconvenient if very large heads were being retouched, as the condition of the medium changed entirely before the negative was finished, and, if from any

cause the work had to be put aside for a day, it was necessary to begin again.

My retouchers complained so much, and so much medium seemed wasted, that I made several attempts to concoct some of my own. At first I succeeded in making a small quantity, but when I attempted to make more I failed. At last I started on a new plan, and, instead of using a hard resin and a slow or non-drying substance to make such a combination of hard and soft resins as would give a film capable of taking the lead. After several experiments, I succeeded in finding the proper proportions of various gums dissolved in a simple solvent, with no addition of slow-drying substance, and which gave a film capable of receiving the lead in a similar manner to working upon paper. Instead of working the lead *into* a more or less sticky film, I now had a film I could work *upon*, for which I claim several advantages. It is ready to work upon as soon as the solvent has evaporated; the film, when once spread, does not alter, as it is quite dry before work is commenced, and at the end of a week will take the pencil as well as at first; and, lastly, the medium will keep in good condition to the last drop in the bottle. This, I admit, is a distinct disadvantage from the maker's and dealer's point of view.

With regard to spreading, I prefer the finger. I cannot get the film even or thin enough if I use rag.

A favourite medium with some workers is the fat oil which is a residuum of turpentine. I tried it once, but only once. It was to me a filthy mess. Others recommended castor oil thinned with turpentine, but I could never do anything with it. I have also tried roughening the film with cuttlefish and resin, and resin alone, but I am like Mr. W. S. Gilbert, who, when an actor introduced some "gag," told him it was very funny, but he added, "I like my own best." HAROLD BAKER.

THE LATE MR. WILLIAM ENGLAND.

THE gentleman whose name is at the head of this notice, and whose loss old photographers must deplore, was one of its earliest workers, having been a most successful Daguerreotypist. Some of his instantaneous examples in that branch would surprise many in the present day. He was the first to take photographic views in America and Ireland. Those of the Exhibition of 1862 were taken solely by himself.

His reputation was not confined to this country, he having been nominated as Juror at the Paris International Exhibitions of 1878 and 1889. In the latter he was chosen foreman of the British Photographic Section, on which occasion he received the thanks of H.R.H. the Prince of Wales, and, although the recipient of many medals, this was his most prized recognition. At the same time he received the French decoration of Officier de l'Académie. He was connected with the Royal Photographic Society for over thirty years, more than half of which he sat at the Council board. Although a man of very retired manners, his vast knowledge of the art he loved was always at the disposal of any one seeking it.—*Communicated.*

THE LATE DR. JOHANN PAUL EDWARD LIESEGANG.

THE following particulars of the life of Dr. Liesegang are given in the *Photographisches Archiv*.

He was born on June 26, 1838 at Elberfeld, and began his studies at the intermediate school there in the year 1843. After studying natural science, chemistry in particular, at the universities of Berlin, Giessen, and Jena, he received the degree of doctor in 1859.

His first impulse to photography came in his fourteenth year, when the photographer, Emden, whom he helped for amusement, erected a studio in the large garden belonging to his father. The outcome of this was, that he published in his sixteenth year a "Guide to Photography," which afterwards by degrees grew into his large "Handbook."

After leaving the university, he founded in Elberfeld a manufactory for albumenised paper and a photographic apparatus factory. These were transferred to Düsseldorf in 1873.

The manufacture of albumenised paper was subsequently superseded by gelatino-chloride paper (aristo paper) which he was the first to place upon the market.

He was the first to introduce into Germany the collodio-chloride process invented by Simpson. From his mechanical workshops the most divers apparatus were sent out, amongst which may be mentioned his own special panoramic camera, and his apparatus for enlarging and optical projection.

At the same time his activity as a journalist and publisher became more extended. In 1860, he founded at Elberfeld the *Photographisches Archiv*. Shortly after followed the *Moniteur de la Photographie*, the editing of which he shared with Ernest Lacan. His *Amateur Photograph* was started in 1887. The quarterly publication, *Lanterna Magica*, was devoted especially to optical projection. The Italian paper, *L'Archivio Fotografico*, was also produced for some years under his direction.

The Inquirer.

*** *In this column we from time to time print questions that may be addressed to individual contributors to our pages, or such as are sent to us with the view of eliciting information from a variety of sources. We invite the co-operation of our readers in rendering this feature of the* JOURNAL *useful and instructive.*

CHROMATE OF POTASH.—J. H. F. asks: "How can I make neutral chromate of potash from the bichromate? I have plenty of the latter, but cannot get the former here. I have tried adding caustic potash, but the result, so far, has not been much to speak of, certainly not to boast about. I shall be thankful for any help."

"PERISHED" INDIARUBBER.—COLLODION says: "I have a pneumatic holder that is some years old, and the ball as well as the disc have both gone wrong. The disc is all cracked and hard, and the ball stiff and inflexible, although it does not show any cracks. Can I do anything to soften them? I am told I can get a new disc, but I suppose the ball will prove a different matter.

DEVELOPING KINEMATOGRAPH FILMS.—CINEMATO says: "I would be glad if you can inform me, through THE BRITISH JOURNAL OF PHOTOGRAPHY, as to the best way of developing the long kinematograph films. I have two or three ways of my own, but, as it requires the assistance of two more besides myself, it is not so satisfactory as I could wish. By starting a discussion in THE BRITISH JOURNAL OF PHOTOGRAPHY on this matter, I feel sure many others besides myself would be interested."

INVERTED ALBUMEN.—F. HAROLD writes: "I have read the correspondence on this subject, and I think E. Freeman's failure with the formula he mentions arises from the use of diluted albumen and too weak soda solution. The formula I have always used—I think I got it originally from Watts's Dictionary—consists of albumen pure and simple and caustic potash dissolved in as small a quantity of water as convenient. With this I don't think E. Freeman will find any danger of the product *dissolving*, but it may be difficult to wash."

SPOTTING PRINTS AND NEGATIVES.—BEATEN says: "Will any one tell me how negatives and prints are 'spotted'—whether the 'art,' if any, lies in manipulative skill simply, or in the use of some special spotting material? I use the best and finest sable pencils, and water colour mixed with a little gum water. With prints I can get on fairly well, as the extra colour does not show much; but with negatives, when I operate on a pinhole, I get enough stuff on to cover a dozen, and, if it is a bigger hole, the colour will not stick at all. I do not know that my sight is defective, but I find great difficulty in getting out the right spot, especially in negatives. Some of your readers may be able to throw out a hint or two, for which I shall be deeply thankful."

PURE WATER.—W. FINLAY writes: "I am greatly troubled with bad water, which comes from a well which is not itself foul, but which is supplied from surface water, and now and then, after heavy wet, we get the benefit of all the filth in the neighbourhood. Of course, for domestic purposes, we have to boil and filter all we use, but this is beyond my power for washing prints, &c.—at least, up to the present. I write now to ask if any reader can recommend me a *cheap* method of filtering large quantities quickly—in fact, a cheap home-made filter. I do not need for this purpose perfectly pure water, as for drinking, but sufficiently so to stand the silver test, and, above all, free from grit."

SULPHOCYANIDE AND THE DOUBLE FIXING OF PRINTS.—J. H. HEMSLEY writes: "I notice that a week or two two ago a correspondent in this column mentioned the use of sulphocyanide as a second fixing bath for prints. I should say to him, Don't use it. With albumen or collodio-chloride it may be no worse than useless, but with gelatine it would prove utter ruin if sufficiently strong to do any fixing at all. Besides fixing the prints it would make them fix themselves to anything they came in contact with. In fact, to be of any use in fixing, the sulphocyanide must be very strong, and then its softening action on the gelatine makes the prints as adhesive as a 'fly-catcher.' They are bad enough when only fifteen grains to the ounce are used in the toning bath."

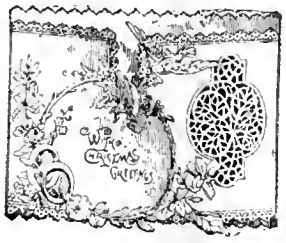
A Retouching Surface for Negatives.—A Country Professional says in reply to J. C. in last week's column: "I some time ago made a number of experiments on the lines suggested in an article I saw in your columns, with the result that I succeeded fairly well in getting a matt surface on the gelatine film, though sometimes it is accompanied by a slight grain, not sufficient to interfere with printing, but rather awkward in delicate retouching. I need not recapitulate all my experiments with different substances, for fortunately I succeeded best with materials at hand in every studio or dark room. The following is the plan I adopt: Let the negative dry after fixing and washing, then lay it for five minutes in a rather weak solution of alum. I cannot give a very definite strength, as plates vary so, but I use five grains to the ounce with some, and as much as ten grains with others. Take it out, and, if the solution does not drain evenly away without leaving drops, blot it off with a clean cambric handkerchief, and allow it to stand until the film has become even and glossy. Then dip it into a dish of dilute ammonia 1 : 10, and leave it for a few minutes, then wash well and allow to dry. It will then have a delicate matt surface, perhaps a faint opalescence, like fine ground glass, and a beautiful tooth for the pencil."

Our Editorial Table.

Houghton's Christmas and New-year's Mounts.

G. Houghton & Son, 89, High Holborn.

Some specimens of mounts suitable for bearing Christmas cards have reached us from Messrs. G. Houghton & Sons. They comprise the folding slip, the plain embossed folding, the plain embossed, plain gold bevelled, fancy gold bevelled, the "frame" slip, and

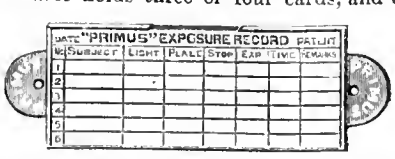


other distinctive varieties. The designs are singularly elegant and refined, and we are sure that photographers and the public will very highly appreciate them. The cuts show three varieties that struck us as being not the least charming of the many submitted to us.

"Primus" Novelties.

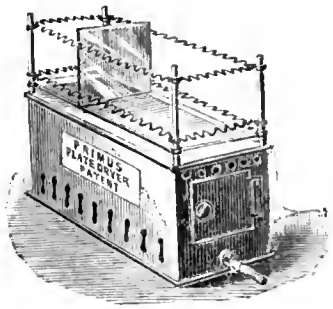
W. Butcher & Son, Blackheath.

"Primus" Exposure Record.—This consists of a neat metal frame provided with screw holes, by which it is attached to the camera. This frame holds three or four cards, and upon these the



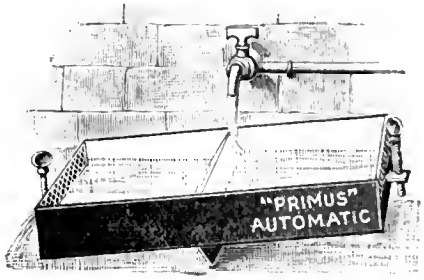
details of the exposures may be recorded. The card is printed front and back, and will accommodate the particulars of one dozen exposures. Fifty cards are supplied with each frame. It is a convenient way of recording exposures.

"Primus" Plate-dryer.—As indicated by the illustration, the plates are supported in wire grooves on the top of the heating plate. Underneath the plate is a box, which forms the heating chamber, through which an atmospheric gas burner runs, and is connected



with the house gas by a piece of indiarubber tubing. It is claimed that plates may be dried by this method in ten minutes, and, intelligently used, it is one that should be found very acceptable when an amateur desires to quickly dry a negative.

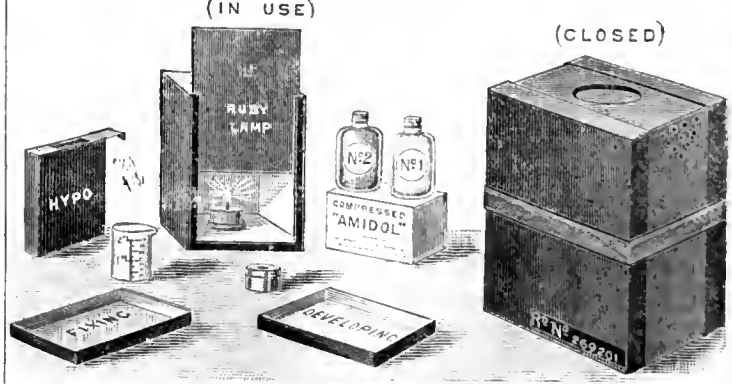
"Primus" Washing Tray.—This is automatic in action, and may be used for either negatives or prints. The tray is placed



under a stream of water, so that it falls *on* the pyramidal division, and into the half of the tray which is off the ground. This half, when full, tilts up the other half, and so causes the stream to fall into the other half. The rise and fall—in other words, the rocking—is adjusted by means of the screws at each end. We can speak from practical experience of this tray as a very useful little bit of apparatus.

The "Traveller" Developing Set.

R. & J. Beck, Cornhill, E.C.



This is a handy little set, that packs up into an extremely small compass, which should be found very useful to those who, when travelling, have little space to spare for their photographic impedimenta. It consists of a ruby lantern, the protecting covers of which serve as developing trays. A partitioned case carries a measure, night-light, and granulated hypo. Concentrated developers in dry powder are given. The trays are coated with a tough enamel, which is

proof against acids and alkalies. The measure is of a convenient form for dissolving the developer. The developer is contained in two small bottles with screw caps, which serve as measures when mixing a solution for use, no weighing being required. The hypo-sulphite occupies the minimum of space.

It is a compact little set, and capable of being very useful to the traveller. The size of the closed packet is about $5 \times 4 \times 3$ inches.

News and Notes.

MESSRS. ELKINGTON & Co. have removed from Church-street to 115½, Abbey-street, Nuneaton.

MR. ALEXANDER FISHER has had the honour of submitting his enamels for Her Majesty the Queen's inspection, who has been graciously pleased to give him a commission to execute one for her.

As already announced, the Annual Meeting of the National Association of Professional Photographers will be held on Monday next, September 28, at Anderton's Hotel, Fleet-street. The President will take the chair at four o'clock. The dinner will take place at seven o'clock the same day at the same hotel.

THE LANTERN-SLIDE EXCHANGE CLUB (ESTABLISHED 1889).—Mr. A. J. Richardson, of Summerville Dore, near Sheffield, who has, for the last four years, been the Hon. Secretary to the above Club having resigned, the vacancy has been filled by the appointment of Mr. J. S. Hawker, of Mutley House, Plymouth. Mr. Hawker will be glad to hear from any gentleman desirous of joining the Club. The subscription is nominal.

THE PHOTOGRAPHIC CLUB.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock on Wednesday evening, September 30. First Travellers' Night, and Mr. H. Snowden Ward will deliver a lecture, with lantern illustrations, and entitled *Shakespeare at Home*. Visitors are welcomed upon the personal introduction of a member, or an invitation card can be obtained from the Hon. Secretary, Mr. F. A. Bridge, 55, Dalston-lane, London.

A GIRL who can see the Röntgen rays has been found by Dr. Brandes, of Halle, who discovered her. Starting from the fact that the rays do not penetrate lenses, he hunted for some one the lens of whose eyes had been removed, an operation performed not rarely for extreme short-sightedness or for cataract. The girl, who had had the lens of her left eye removed, was able to see the light with it, though the right eye, which retained its lens, could see nothing. Dr. Brandes asserts that the rays affect the retina of the eye, and, if any one's head is enclosed in an opaque vessel near the source of the rays, the light can be seen even with closed eyes.

KITE PHOTOGRAPHS OF BOSTON.—Mr. William A. Eddy, of Bayonne, N. J., has succeeded in making several distinct photographic views of Boston from a great height by means of a camera supported from kites. The kites were of the tailless type used at the Blue Hill Observatory, where an altitude of 7441 feet was obtained, and were six and seven feet in diameter. Four to eight of these kites were required to support the camera, depending upon the strength of the wind. Distinct views were obtained of the Common, Beacon-street, Commonwealth-avenue, Charles River, and the outlying suburbs, and Mr. Eddy estimates that in one of the views the camera was, at the moment of xposure, 1500 feet above the pavement.

LEWISHAM CAMERA CLUB.—An Exhibition of Members' Work will be held on Monday and Tuesday, September 28 and 29, 1896, in the Lecture Hall of the Lewisham High-road Congregational Church. Numerous examples of work in the various processes of photography will be shown, including a unique exhibit by Mr. A. L. Henderson of early and present photographic work, including a splendid collection of ceramic enamels. On each evening there will be a demonstration of *Platinotype Printing and Development*, by Professor Carlton J. Lambert, M.A., F.R.A.S.; *Printing and Enlarging on Bromide Paper*, by Mr. H. L. Davis. A choice collection of lantern slides will be shown on the screen. Selections of instrumental music. The Exhibition will be opened on the first day by the President, Mr. B. Davidson; on the second day by Mr. A. Horsley Hinton. Doors open on Monday at seven p.m., and on Tuesday at three p.m. Admission by ticket, price 6*d*. each.

THE PHOTOGRAPH OF TYNAN AND HOW IT LED TO HIS IDENTIFICATION AND ARREST.—Mr. Hemery, of Hanover-street, Peckham writes: "Shortly before the assassination of Lord Frederick Cavendish and Mr. Burke, Tynan was a frequent visitor to my studio, he living only three or four minutes distant, remaining in conversation often for an hour or more to talk about distressed Ireland. Close to him lived another irreconcilable, Frank Byrne, and the police from Scotland Yard, taking advantage one day of his absence from home, made a raid upon the house, and, finding there a photograph of a gentleman in the uniform of the Queen's Westminster Volunteers, brought it to me, asking if I knew who it was. I replied, 'Certainly I do. I hope there is nothing wrong with him.' After some conversation, I began to think—recalling other circumstances, and knowing that Tynan was in Dublin on the fatal 6th of May—that it might, perhaps, be none other than the mysterious 'No. 1,' about whom there was so much mystery. Having hazarded that opinion, I lost no time in seeing Mr. Williamson (Head of the Criminal Investigation Department), and, after a private interview, at which I gave my reasons for the suspicion, the photograph was sent to Dublin Castle, where it was at once identified by Carey and others as the man, 'No 1,' who controlled and directed their movements. 'And a very good portrait too,' said Carey. After that there was no difficulty, as my book supplied the name and address of the unknown, and, the warrant filled up, 250 copies were printed and distributed at every seaport in the Kingdom within twenty-four hours. But the bird had flown. The portraits were taken about ten days previous to the dreadful event in Phœnix Park, and it seems evident that the man desired that his family should possess a memento of him in case he was caught and condemned for the crime so soon to be committed."

Patent News.

THE following applications for Patents were made between September 7 and September 12, 1896:—

SCREEN KINETOSCOPY.—No. 19,716. "Improved Apparatus for Enabling Photographic Images to be Taken, Projected, or Viewed in Rapid Succession." F. W. TAYLOR and A. LOMAX.

DEVELOPING APPARATUS.—No. 19,726. "A New or Improved Apparatus for Developing, Fixing, and Toning Photographs." Complete specification. W. GRUNOW.

CERAMIC PHOTOGRAPHY.—No. 19,917. "Improvements in and connected with Ceramic Photography as applied to Watches and Time-piece Dials having a Ceramic Base for the Figures." H. NICHOLLS and R. CROWE.

FILM-HOLDER.—No. 19,923. "An Improved Mechanical Appliance for easily Attaching and securely Holding Photographic Films Flat to Rigid Supports." W. KIDSTON.

FILMS.—No. 20,080. "Improvements in Means or Apparatus Employed in the Manufacture of Photographic Films." Complete specification. A. C. EDWARDS.

DRAINING RACKS.—No. 20,179. "Improvements in Photographic Washing and Draining Racks." O. F. LEHMANN.

CAMERA STANDS.—No. 20,251. "Improvements in Attachments for connecting Photographic Cameras, Surveying Instruments, and the like to their Stands or Tripods." Complete specification. D. H. T. PEPLOE.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

September.	Name of Society.	Subject.
28.....	Bradford.....	Smoking Concert.
28, 29	Lewisham	Exhibition of Members' Work.
28.....	National Association of Professional Photographers ...	Annual Meeting at Anderton's Hotel, Fleet-street. 4 p.m. Dinner at 7.
28.....	North Middlesex	*Lantern Slides and their Production.* E. Dockree.
29.....	Hackney.....	*The Half-tone Process.* W. Gamble.
30.....	Birmingham Photo. Society ...	Last Day for sending in Competition Pictures, August Excursions, Lill es-hall and Worcester.
30.....	Borough Polytechnic	Annual General Meeting.
30.....	Croydon Camera Club	Excursion: Chaldon. Leader, J. Smith.
30.....	Leeds Camera Club	Beginners' Lecture.—I. *Choice of Apparatus.* C. C Vevers.
30.....	Photographic Club	*Shakespeare at Home.* H. Snowden Ward.
October.		
1.....	Liverpool Amateur.....	Smoking Concert.
1.....	Woodford	*Intensification and Reduction of Negatives.* Mr. Malby.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

SEPTEMBER 17,—Mr. A. Haddon in the chair.

Mr. W. F. Slater brought up and subsequently presented to the Association a couple of mechanical prints, and a discussion ensued as to the method of their production. Mr. Slater remarked that they could be printed off as quickly as letterpress, while their cost was very low, and he thought they might be a serious competitor with photogravures, to which process they bore a marked resemblance.

Mr. MACKIE said there was a photogravure process in which there was a grain of a network character in addition to the ordinary powder grain, and he thought the prints shown might be by that process. On examination there was a distinct appearance of cross lines.

MOUNTING P.O.P.

Mr. BAYSTON opened a discussion on the best way to mount gelatine papers. From their first introduction he had found it a very different thing to albumenised paper, but he had adopted the following plan, which, however, he did not assert was necessarily the best, but it was still very good. The prints, after being trimmed, are soaked for a short time in water and drained, and then placed face downwards, one upon another, to any number, upon a piece of glass. The surface moisture is then dabbed off the top one, and starch paste or Higgins mounter, which answered as well, applied with a brush. It is then transferred to the mount, if possible avoiding handling the corners, and is rubbed down with a wet cloth or sponge. He did not use alum with the prints.

Mr. MACKIE said the whole secret of mounting P.O.P. prints consisted in rubbing them well down.

Mr. HENDERSON had saved much trouble by rolling the prints with a rubber roller, with a piece of waxed paper between it and the print. Cloth or paper would stick to the surface.

Mr. MACKIE had mounted a large number with the aid of a cloth and roller, and did not find the cloth stick, and any impression left by it would dry out.

Mr. HENDERSON showed a print toned with the combined lead and gold bath, originally mounted in the year 1859 with starch, and which he had occasion recently to remount. He experienced great difficulty in removing it from the mount, and then only with the aid of such hot water that the whites were yellowed.

PHOTOGRAPHIC CLUB.

SEPTEMBER 16,—Mr. H. P. Smith in the chair.

Various objects of interest were shown. Mr. Charles Wallis showed some of the photographs he had made whilst upon his holiday tour at Fécamp. He promised to give the Club an evening, entitled *My Holiday Trip*, on December 9, illustrated with lantern slides.

The subject of the evening was—

FIXING PRINTS.

A member stated that he had recently experienced a liability with certain samples of hyposulphite to reduction of the image. This was most noticeable with a freshly made fixing bath, and the reducing effect apparently wore off after the bath had been used a little. He had subjected the salt to examination, and found it to be a reasonably pure commercial article, and without trace of free acid. He added that a bromide print placed in the bath made with the hypo to which he referred would turn to a brown colour after about thirty minutes' immersion.

Mr. BRIDGE said he had once left a print for four days and nights in an old hypo bath; it had turned to a beautiful purple, and he thought he had accidentally discovered a new process, but he could not repeat the experiment with success.

Mr. MACKIE said that twelve or thirteen years ago Mr. Garrett had shown some beautiful lantern slides at the Club. He said he (Mr. Garrett) had toned them by leaving them in the hypo all night. This effect was probably due to the silver dissolved in the bath rather than to any direct action of the hypo itself. He added that he (Mr. Mackie) thought it probable that the liability to fade in silver prints may often be attributed in part to this cause.

Mr. BRIDGE raised the question as to whether Professor Haddon's experiments were on all fours with ordinary practice.

Mr. MACKIE thought they were. He believed that Professor Haddon's original experiments had been made with pieces of paper cut from the white skies of landscape prints. Professor Haddon demonstrated that there was always silver left in the whites of a print, and possibly this was due to the cause he (Mr. Mackie) had already referred to, viz., the presence of a salt of silver in the hypo bath.

Mr. WILLIAMS asked if any member could tell him how to prepare a print so that it would certainly fade. Some time since he had been very anxious to produce a print which would not last, and he had purposely left much of the hypo in the print; to his surprise, this picture had not faded twelve months after it was made.

THE ANNUAL OUTING.

Members and friends of the Photographic Club, to the number of thirty persons, proceeded, on Saturday, the 19th, to the Bull and Bush, at Hampstead, to enjoy what has been for some time regarded as an Annual Tea. Some of the members met earlier in the afternoon and rambled over the Heath and surrounding country. At six o'clock Mr. Frank Haes took the presidential chair, supported by Mr. A. Cowan, in the vice-chair, and a substantial tea was done full justice to.

Gospel Oak Photographic Society.—On September 15, Mr. Ramsay gave a demonstration of

SOLIO PAPER.

He commenced by a reference to combined baths, which he condemned, on th ground that the prints toned in this manner were not permanent. The bath he was going to use was in two solutions, one a solution of sulphocyanide, and the other a solution containing acetate of soda and gold chloride. Treating of the defects in prints, he said that a pink or green tinge in the half-tones and high lights was due either to heat or to an excess of sulphocyanide. He then proceeded to tone some prints which he had brought to the meeting, and said that, on putting them into the bath, they became covered with a sort of bloom which appeared on the surface, and which would make them appear, by reflected light, over-toned, before the actual toning had commenced. The proper way to judge the progress of toning was to examine the prints by transmitted light; and, for warm tones, they should be removed from the bath whilst there were still some traces of warmth in the shadows; but for cold tones, inclining to purple, they were not to be removed until all traces of warmth had disappeared. He also said that, the longer a print was to be toned, the further the printing must be carried; and, further, that the temperature of the bath should not exceed 65° to 70° F. The prints should be handled as little as possible, since perspiration produces a red stain, particularly with matt Solio.

Hackney Photographic Society.—September 15, Mr. E. Puttock in the chair.—In reply to a question raised as to the darkening of a solution of potassium chloro-platinite, opinion was expressed as to the effect that such darkening did not practically interfere with the toning power of the solution providing that the metal was not precipitated. Mr. HENSLER advised the addition of a few drops of nitric acid to the solution when first made up; it would then keep clear. Mr. WESTCOTT said that, if precipitation took place, an addition of a little nitric acid would redissolve the precipitate. A question was asked as to the best method of reducing over-printed prints. In reply, it was said that both Farmer's and Belitzki's reducers respectively could be used, but that, unless the original negative were not in existence, it were better to make a fresh print.

North Middlesex Photographic Society.—September 21, Mr. H. Smith in the chair.—Mr. J. W. MARCHANT gave a demonstration on—

THE PLATINOTYPE PROCESS,

especially intended for beginners. He dwelt on the simplicity of the process, and said the main thing to guard against was damp. He developed a number of prints, some from negatives supplied by a few of the younger workers, and they included a few very fine prints, supplied by Mr. Humphries, of the Platinotype Company. He showed what could be done in the way of getting out detail and keeping back too dark shadows by means of glycerine and local development with different strengths of developer. A very able demonstration was brought to a close by a few words from the PRESIDENT (Mr. Mummery), in which he said he hoped to see some result from this on the walls of the annual Exhibition, by members who have not used this process taking to it in place of silver printing.

Ashton-under-Lyne Photographic Society.—Aquarius emptied all his watering pots upon the unfortunate photographers who went to Bolton Wood on Saturday, September 12, under the leadership of Dr. Hamilton. Other excursionists can make a tolerable shift whatever the weather may be. They can take their ease at an inn, and, if mere sightseers, they can even plod along in spite of the pelting of the rain, and enjoy themselves to a moderate extent. But photography is always associated with a fair amount of daylight and not a small allowance even of sunshine. The annual trip of the Ashton Photographic Society, under the guidance of the President, is looked upon as an occasion for establishing a new record in the number of plates usually exposed. On such a day as Saturday was, with all the usual essentials at a minimum, there was little to be gained by attempting to get pictures,—

> "From mid noon the rain
> Had fallen in torrents, all the mountain tops
> Were hidden, and black vapours coursed their sides."

Everything wore a dismal and bedraggled look. Mist and darkness accompanied the heaviest downpours. If the day had been alike all through, it would have been about as bad as it possibly could be; but then there were intervals of comparative illumination, which rendered photographic work not altogether impossible. The noble old Abbey looked almost dark and frowning, if such lovely places ever can wear a forbidding aspect. One cannot help deploring that the Reformation should have been accompanied by the dismantling of so many of these ancient structures, necessitating the erection of a great many inferior religious houses. It was thought the rookeries must come down to disperse the crows, but one now sees that no such necessity really existed. We see at Bolton Abbey, side by side, the preservation of one part as all might have been preserved, and the ruin of the rest, which, at no great expense, might also have been preserved for religious or scholastic uses. Some of the men of that old destructive time have left on record similar sentiments; but, in great national movements, the most violent course is commonly adopted and afterwards repented. However, the very hand of the destroyer has only made these old places more revered and admired than they would have been had they come down to us intact. A stately ruin comes almost to be worshipped by the poet and the painter, who would have seen nothing in the original building to inspire raptures such as Sir Walter Scott's over Melrose seen by moonlight. A ruin, in like manner, attracts the photographers with a subtle magnetism. Why should it be so? Various people have their interpretations. "Age, like distance, lends a double charm," says one; but a building quite as old that is entire excites no such feeling. Some absurd conclusions, we think, have been drawn, such as this :—

> "Thinkest thou the thousand eyes that shine with rapture on a ruin
> Would have looked with half their wonder on the perfect pile?
> And wherefore not—but that light hints, suggesting unseen beauties,
> Fill the complacent gazer with self-grown conceits?"

This is a very imperfect analysis of one's feelings. The sentiment of pity is stirred in the breast, as it would be by the spectacle of an "archangel ruined," or, for the matter of that, by some poor man who has ruined himself and become a miserable wreck. The mind is carried back direct by the ruin of to-day to the far-off time when the building was in use. It is not now associated with any modern purpose, and is looked upon as a sort of miraculous survival, wonderfully preserved from a lost antiquity. It looks desolate, forlorn, and neglected, and one's sympathy naturally flows out to it. Nature does its part to beautify the old pile by methods which are carefully battled against in modern structures; and Nature, having her own sweet way, clothes the rude stones with a more delicate vesture than ever covered the "perfect pile" in all its glory. It is a true sentiment, which resents anything like "restoration" applied to a ruin. No ruin can be restored. The only thing that can be done is to protect it from too rapid decay, and this duty is now better discharged than it used to be in England and elsewhere.

1896. FORTHCOMING EXHIBITIONS.

Sept. 25-Nov. 7	Photographic Salon, Dudley Gallery, Piccadilly. Alfred Maskell, Dudley Gallery, Piccadilly.
,, 28, 29	Lewisham Camera Club. H. M. C. Spruut, 192, New Cross-road, London, S.E.
,, 28-Nov. 12 ...	Royal Photographic Society. R. Child Bayley, 12, Hanover-square.
December 3, 4.....	Aintree Photographic Society. E. P. Heron, 2 Tilney street, Orrell Park, Aintree, Liverpool.
Dec. 1896-Jan. 1897	Bristol International.

Correspondence.

MR. CHILD BAYLEY (AND OTHER AUTHORITIES) ON ART.

To the EDITORS.

SIR,—I think very few recognise what an extremely clever joke was that paper of Mr. Child Bayley's on *Photographic Societies and Photographic Art*. That our dear old friend Robinson should have gone into hysterics over it is hardly evidence of the fact, for a baby might deceive him, but that such wary birds as Davison, Maskell, and Horsley Hinton should have allowed their tails to be salted in such a simple manner I am surprised at.

Mr. Bayley knows nothing about art, they one and all tell us. Perhaps not, but he has, undoubtedly, a considerable knowledge of human nature, and he has used his knowledge with the most admirable judgment of the weakness of his victims.

Blood and thunder! is this upstart minion of an institution which has dared to succeed, when we have pronounced its extinction, to question our self-constituted authority to decree the fashions in art? No! Let us go for him.

And they go, which was just what he wanted.

The "veteran photographer," let us give him the title he loves, leads the attack, if attack it can be called, for his playful fancy disarms his pen. His heavy artillery are but firework bombs, which, with a loud explosion, burst into a radiant display, then fade into nothingness. His small arms are as dangerous as the confetti of the carnival. Life, to him is one long carnival. He takes nothing seriously, and no one takes him seriously.

The saturnine Maskell treats the matter in an entirely different manner. He evidently recognises the difficulty of the position, and, finding it unassailable, and to make a demonstration, fires bullets into the air, and they fall amongst his allies.

Davison endeavours to make us think he despises his enemy, and, assuming calmness, apostrophises the clouds, but he betrays his agitation. What a childish evasion of the point that was to suggest that Mr. Bayley should produce a work of art as an example. Mr. Bayley was not discussing art as Mr. Davison and they all pretend to infer. He was denouncing the tommy-rot that is inflicted upon us as art-teaching.

Perhaps the most amusing record is that of Horsley Hinton. He flings himself about something after the fashion of a Drury-lane termagant, who, after a night of excess, is being conducted to the police station. There is no beating the bush about him. The matter is a too serious one to him to stand upon punctilios, as he carefully misquotes the paper and the discussion which followed it, and then demolishes the phantoms he has raised.

In congratulating Mr. Child Bayley on his successful production, we ought not to omit to thank the four gentlemen who have played as comedians in the piece. We have enjoyed a hearty laugh at their expense, for which I am sure we all hope they will forgive us.

Secondly, they have all done more than a little towards the advancement of photography in its artistic application, and we appreciate their services in this direction. We may smile at their vanity, but none the less we recognise that in many ways they are worthy of admiration.

In order to give the dear old boy an opportunity of slaying me with his quill, may I sign myself ANOTHER OLD MEMBER.

PHARMACEUTICAL EDUCATION.

To the EDITORS.

GENTLEMEN,—The following conversation between a young Pharmaceutical Chemist and a customer shows the extent of their English.

"A customer asked the chemist if he had any good vinegar, as where he got it last it was poor, although called 40's. The chemist assured him his was very good, being elevens. The customer, knowing a little about specific gravity, could not understand how a vinegar of specific gravity 1·015 could be better than 1·052, but took it and found it very good; next time he asked the chemist if he was sure it was elevens, and he said yes, quite sure, he would show him the invoice, and, lo and behold! on seeing the invoice it was by Hill Evans, the well-known makers—a good specimen of silent H." *Chemist and Druggist*, please quote.

MEDICO.

THE POISONS ACT.

To the EDITORS.

GENTLEMEN,—Will you allow me to point out one or two inaccuracies in your leader in this week's JOURNAL?

1. There is no law "compelling the vendor (of poisons) to be a pharmaceutical chemist." I am not one, and yet am legally qualified to sell any poison on the schedule.

2. No one can sell, as you seem to suggest, methylated spirit in *any* quantity, or of *any quality*, either "old" or "new," unless he be an authorised methylator or licensed retailer.

3. The Pharmaceutical Society does not allow widows of chemists, as such, to carry on the business of their deceased husbands, nor is the widow legally entitled to carry on the business in partnership with a qualified chemist. My mother was a chemist's widow, so I can speak from personal experience.

4. You sneer at the idea of the "safety of the public" being the *raison-d'être* of the Poisons Act. Might I call your attention to the fact that the number of deaths, accidental and otherwise, from unscheduled poisons is on the increase, while those from scheduled poisons are decreasing every year? Take carbolic acid for instance. This article is sold indiscriminately by grocers and oilmen, and the number of deaths caused by it alone averages at present one per day. Is it too much to suppose there is some connexion between the unrestricted sale of this poison and the number of agonising deaths produced by it? Incidentally I may remark that the Pharmaceutical Society have done their best for many years past to get carbolic acid put on the schedule; but you, in the interests of free trading, will be glad to know, without avail. And so victim after victim (some innocently, some with fixed intention) go to their doom, and undergo one of the most horribly cruel deaths it is possible for poor humanity to endure, and all in the name of liberty.—I am, yours, &c., A TRADES UNIONIST.

THE POISONS EXCITEMENT.

To the EDITORS.

GENTLEMEN, — The numerous paragraphs and communications appearing in your last number upon the subject of poison-vending, are calculated to provide considerable amusement for a section of your readers.

Chemists *are* frequently prosecuted by the Medical Defence Association for prescribing, even as photographic dealers are prosecuted by the Pharmaceutical Council, for selling poisons. But I never yet heard of a chemist so legally prosecuted and fined, writing to his trade periodical and kicking up such a ridiculous hullabaloo because the law would not allow him to do just as he pleased.

A chemist on the Continent has a higher status and greater privileges than a chemist in England, but even in England he has a status, a charter, and a title, so that no photographic dealer, not being a legally qualified chemist, may assume the title of "chemist;" neither may the chemist assume the title, not having earned it, of "doctor," without rendering himself liable to prosecution and fine.

But what *is* a "Photographic Dealer?" We find tinkers, tailors, ironmongers, haberdashers, furniture brokers, Jacks-of-all-trades, limited liability riggers, *et hoc genus omne*, cheerfully innocent of chemistry, optics, mechanics, and other collateral sciences, and with a smattering of photography, "going into" the photographic trade on the celebrated "sell-the-goods" principle, as exemplified in the Law Courts, announcing themselves as photographic dealers, and clamouring for the privileges of the chemist without paying the fees, passing the examination, or proving their efficiency in any way whatever. These gentlemen modestly suggest that it may be necessary for such an inferior person as a chemist to be placed under legal restrictions in the vending of poisons, but that such a genius as a photographic dealer ought not to be subjected to the same laws. A photographic dealer is so entirely satisfied as to his own immense personal superiority that to request him to pass an examination would be an outrageous insult.

Your correspondent "Medico" relates an interesting anecdote of a "cutting" chemist who sold a Frena camera at a disconnt to a customer, but could not show him how to open it. If your correspondent would be kind enough to write and relate the incident to Messrs. Beck & Co., of Cornhill, the proprietors of the Frena camera, they will have a little matter of business to adjust with the "cutting" chemist, who will find that this time he has been so sharp that he has "cut" himself.—I am, yours, &c., PHARMACIAN.

TAKING PHOTOGRAPHS FOR NOTHING.

To the EDITORS.

GENTLEMEN,— What's all the pother about? A firm sending out circulars? Some who choose to accept are forthwith to be held up to scorn, black-listed, or hung right off. By whom, pray? First, your noble selves say they deserve the reprobation of their fellows. For what, Mr. Editor? Why, conducting their own business according to their own lights. Now, what in the world, Mr. Editor, have you got to do with me or my business, I would like to know? Then follows friend "Cosmos," inventor-patentee of the black-list. I rather like "Cosmos," you know; so leave him and his bunkum severely alone. Another growler is the son of the member of a firm who make a practice of placing show-frames in surrounding towns, filled in with a very few choice specimens, which are well worth 21*s.* cabinets and 10*s.* 6*d.* *cartes*, and then how well the party in the town obtains that price for similar work, but they place a very small frame, and very large cabinets 12*s*, *cartes* 5*s.* per dozen. Looks very like throwing stones and

living in glass houses, don't it? Then, a short time ago, friend Robinson was at us, poor d——s, for not joining the Convention or some such gushing so-called outing, for we must be doing poor business, not able to afford a spree once a year; but whisper says, Some of those might have paid their stock-dealers' account, ay, and some of the mashers with snaps in hand paid the tailors. Now, I try to "Mind my own business," "Never find fault with amateurs," but oblige them by turns; pay my way and have an outing when I require one on the quiet.—I am, dear Mr. Editor, ONE OF THE POOR SLAUGHTERED ONES.

P.S.—For your information and the publishers, who have caused the commotion, if the coupon-holder or they expect to get a cabinet for what I charge and get 4*s.* 6*d.* for, why then I take them for——

ABOLISH THE PATENT LAWS.

To the EDITORS.

GENTLEMEN,—Having always considered the technical press an educational force, I feel that those who use that medium to ventilate their ideas should restrain themselves within an educational limit. "Personalities," or "Whose the first foot?" are not instructive, and should have no place in the pages of our technical journals.

Your correspondent, in replying to my cry, *Abolish the Patent Laws*, in last week's issue, has propagated a conundrum I cannot solve. He admits the Patent Law is a fraud—a device to catch inventors and land them into serious law expenses!—and then he charges me with the nefarious opinion that I advocate stealing other people's brains! and with a barefaced inconsistency advises all inventors to be careful to secure their inventions by patent; for what?—that they may become a prey to the lawyers.

The absurdity of stealing brains! why, one cannot steal brains unless you cut off the head and run away with it; and, as for ideas, they are not a commercial article of property, and, therefore, they are *pro bono publico*—not patentable.

If your correspondent will refer to the opposite page of the JOURNAL, same issue, *re* "*Who Invented Kinetoscope?*" he may learn, practically and personally, a confirmation of what I advanced, urging the removal of all restrictions on progress. I again reassert that the time has come when we must blot out of our dictionaries the word *inventor*. There is, in the present day, no such person possible as an inventor who can truly claim that he arrived at his discovery through the exercise of his individual thought, or that he had not been coached to it by what he had read, or had seen or been told, probably conveniently forgetting all about it. Where, may I ask, does the "stealing" come in? Most certainly with the patentee.

Your correspondent admits logically that the publication of the specification of a patent affords the opportunity to thousands of thieves dodging around to see how much of other peoples' ideas they can appropriate, without getting *run in;* yet, after all, he advises the inventor to have his specification published.

Oh, innocent student of the higher intelligence, you must indeed be very much so, to descry against what we all know to our cost (and some to their profit) is rampant at every hand's-turn; why, the whole population of the entire world are copying or stealing, if you will, from one another whatever they can appropriate profitably.

If we had not our Shakespeare to fall back on, most of our orators would prove very shallow brained indeed, and if it were not for the wide-spread existence of a public press, which has produced this higher intelligence of which my friend complains, there would be fewer patentees of the mushroom hot-bed sort.—I am, yours, &c.,

Dublin. JOSEPH LEWIS (a plural patentee).

COLE'S RISING AND FALLING FRONT.

To the EDITORS.

GENTLEMEN,—After considerable trouble and expense to me in bringing out and perfecting the patent (both English and American) of my flexible rising and falling front for cameras, and after the eulogistic opinions of the same by the whole of the photographic press, I need hardly tell you how astonished I was at reading the statements contained in your issue of January 17 last (which apparently was attributable to Mr. Foxlee, when he showed the model of a camera front which had been made by Mr. Hare), 'that it included all the salient features of a new patent camera which had been recently exhibited at the Club;' and, again, in your issue of February 7 last, that this same model, which Mr. Hare then presented to the Club, 'contained the principle of a newly patented camera which had been recently shown to the members, and for which claims of originality had been made and contested by certain members.' These remarks applied to my patent, and I felt at the time that they were most unjust, as the model referred to does not, in any way, contain any of the principles of my camera, but I took no further notice of it until it was drawn most clearly to my attention that the statements made were doing me irrreparable injury, as I found than certain manufacturers before whom I placed the camera for sale had stated that "the idea had been played out for a number of years," and refused to entertain my application to them, giving as their authority and reasons the statements before mentioned, *which they believed to be true*, and *that Mr. Hare's model was identical with my flexible front.*

This being so, I then took steps to bring the matter before Mr. Foxlee, and also wrote to the Hon. Secretary of the Photographic Club on the subject, who read my letter to the members of the Club at a meeting held on August 5 last, with the result that the members (including Mr. Foxlee himself) unanimously came to the conclusion that Mr. Hare's model *was not* the same as my invention, and the Hon. Secretary of the Club wrote me a letter in these words: "I was instructed to write you that it was the unanimous opinion of the members present that the rising and falling front model presented to the Club by Mr. Hare is *not* the same as your invention."

This, to an extent, was satisfactory to me, as showing that a mistake had been made, although it has not, up to the present, removed the damage done me, as any statements emanating from such a Club (bearing the highest reputation, as the Photographic Club does) are naturally taken for granted by the rest of the world (who have not an opportunity to judge for themselves) to be correct and well founded; but I hope, by the publicity that has been given to the contradiction, that I may have the benefit due to me for the *originality of my patent* and the labour bestowed upon it. I was very pleased to note in your issue of August 24 last that Mr. H. C. Rapson had called attention to this subject, for which I thank him.

I may mention that the Judges at the Stanley Show of 1895 recognised its value and awarded it the silver medal.

Thanking you for having allowed me to take up so much of your valuable space, I am, yours, &c., JAMES COLE.

FREE LANTERN LECTURES FOR SCHOOLS, &c.

To the EDITORS.

GENTLEMEN,—Last year, through your courtesy, we were able to draw the attention of your readers to an effort we were making to provide Board and National schools, evening classes, temperance and religious societies, Y.M.C.A.'s, Colleges, &c., with lantern lectures. As a result, we had many applications from teachers and others anxious to use these lectures and slides. Knowing the difficulty which many teachers experience in finding subjects likely to be of interest to their pupils, &c., we have been encouraged by last year's experience to once more make the same offer. This season we are sending out two new lectures, respectively entitled *Behind the Scenes of Popular Journalism* and *Popular Authors and their Work*, each of which, we think, will provide a pleasant evening's entertainment. Both subjects have a distinctly educational value, and, whilst being amusing, the lectures have in them nothing that could offend the most fastidious taste.

Will you permit us to say that we shall be happy to loan these lectures and slides to any of your readers who may like them during the coming season. We shall be delighted to send conditions and full particulars on receipt of a stamped, addressed envelope.—We are, yours, &c.,

GEORGE NEWNES, LIMITED.

9, 10, *and* 11, *Southampton-street, Strand, W.C., September* 16, 1896.

A CORRECTION.

To the EDITORS.

GENTLEMEN,—I find that, when criticising R. E. Liesegang's article on *The Solarisation of Dry Plates* in your issue of August 28, 1896, p. 554, I did not quite grasp the correct meaning of one of his statements, and regret that, in consequence, I misquoted him, and made one or two unnecessarily sharp remarks.

In the translation which I was using (THE BRITISH JOURNAL OF PHOTOGRAPHY, June 12, 1896), the sentence in question is rendered: "It is impossible to prove or to controvert this theory of solarisation, in the development of dry plates, by experiment, either by exposure through the back or by stripping the gelatine film from the glass before development." On comparison with the original, I find that a rather clearer rendering of the meaning would be as follows: "The experiment of exposing the plate from the back or of stripping the gelatine film from the glass before development will not prove or disprove the correctness of this theory of solarisation."

My misquotation does not affect the line of argument I was using.—I am, yours, &c., F. KROHN.

Wealdstom, R.S.O., September 21, 1896.

A WARNING.

To the EDITORS.

GENTLEMEN,—A man, described as about five feet ten inches high, with brown hair and sandy whiskers, wearing a black coat and waistcoat, and brown trowsers, carrying a flat case, covered with oilcloth, similar to an ordinary club-picture canvasser, has been going around Aberdare and suburbs, from house to house, inquiring if any one had any photo-

graphs they would like to have copied. The price to be 1*s.*, and the work would be brought in one week.

He would ask for prepayment, and, on being asked his name and address, he said he was agent to Lendon Berry, & Co., of Commercial-street, Aberdare, but did not give his own name and address. He obtained 6*d.* each from two different persons, who have applied to us for the work, as the man hae not brought it to them according to his promise, and they were very much put out on finding that we had no such person in our employ.

As it is likely this swindler is still pursuing his nefarious occupation in this or neighbouring districts, we have no doubt, if you will kindly insert this letter in your paper, it may stop his little game by drawing the eyes of professionals to any one answering the above description, and, if we can get on his track, we will most certainly prosecute him for using our name for such a purpose.—We are, yours, &c.,

LENDON BERRY & Co.

The Globe Studio, 47, Commercial-street, Aberdare, South Wales.
September 15, 1896.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & Co., 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:—

Albert George Lewis, 62, Shaw Heath, Stockport.—*Photograph of Stockport Rugby Football Club mounted on advertisement sheet.*

Charles Henry Evans, 12, St. Helens-road, Swansea.—*Six photographs of children.*

Thomas A. Moryson, Montague-place, Dumfries.—*Photograph of Robert Burns's tomb, called mausoleum, at Dumfries, Scotland.*

RECEIVED.—PHARMACIAN; J. LEWIS (Dublin); H. WRAGG; and others.

STUDIO BLINDS.—R. STOCKER. The lighter material of the two sent will be the more suitable for blinds during the winter months. For the summer the darker would be the better.

ROYAL ARMS.—S. E. G. The photographs being accepted, and a note of approval and thanks received in return, does not entitle you to the use of the Royal Arms, even on your circulars.

PORTRAITS AT NIGHT.—S. STEPHENS. If the current is laid on in your street, by all means adopt the arc light in preference to a number of incandescent gas lights. It will cost more to instal, but that will be amply repaid by the extra convenience and utility in working.

BLOOD ALBUMEN.—W. COX. Blood albumen is largely used by calico printers, and it is usually supplied by the makers in large quantities only. It is, however, to be had of many drysalters in London. Skilbeck Brothers, Upper Thames-street, will probably supply you with a few pounds at a time.

PRINTING BY ARTIFICIAL LIGHT.—T. MICHELL. Printing-out papers can be printed by the electric light, but the exposure will be very long, which will, of course, make the work very costly. Still, it is possible. If the work must be done by artificial light, will not one or other of the development methods answer?

LENSES.—PIE RAPRONE TE. All the lenses named are good. That numbered 2 is slower in action than the others when they are worked with their full aperture. The maker whose lens you have returned also has a good name. It is against our rule to recommend any particular maker's goods in preference to any others.

PROCESS WORK.—EXPERIMENT. Although wire gauze, muslin, crape, netting, &c., were used by the early workers, or rather experimentalists, they have now all been discarded for the ruled screen. You had better obtain a properly ruled screen for your experiments. A small one—say the half-plate size—is not a costly affair.

PROCESS NEGATIVES.—S. WARMAN. The sale of collodion is not prohibited, and there is no difficulty in getting it, for negatives, for process work. Indeed, few negatives are taken, for that process, that are not on collodion. Apply to Mawson & Swan; they will supply you with any quantity. There are some restrictions as to its carriage by railway, but they are not great.

WETTED NEGATIVE.—C. WHITE. If the wet negative, with the paper in contact with it, was allowed to remain for several days, and become dry, there is little doubt the negative is utterly ruined. The paper may be got off by soaking in water, and then carefully rubbing it off; but the stains on the negative, we fear, are not to be got rid of. A solution of cyanide of potassium may be tried, however.

SHUTTER. T. TODD sends us a drawing of an instantaneous shutter, and asks us if it is sufficiently novel for him to secure a patent for it. He can certainly obtain a patent for it, supposing no one opposes the sealing of it; but we should be sorry to express any opinion as to the validity of the patent in face of the hundreds of shutters that have from time to time been described or patented.

PROCESS WORK.—EXPERIMENT. If the example sent is the sharpest negative the lens will take with *f*-48, it is no use for process work. The screen is only sharp for a few square inches in the centre of the negative. You might try with a still smaller stop, and focus more towards the margin of the plate; but, any way, you cannot make it cover the size of plate you desire. You must get one with longer focus and a flatter field for process work.

CARBON PRINTING.—CARBON NOVICE. We cannot understand the tissue being insoluble immediately it is dry, when it was dried "within the space of seven hours in a perfectly pure atmosphere." It certainly should not be so. The only thing we can suggest is that there was something wrong with the bichromate—perhaps unduly acid. Try the addition of a drachm or two of liquor ammoniæ to each pint of the solution, and do not let the temperature of the drying room exceed 70° Fahr.

ENLARGED NEGATIVE.—J. A. T. asks: "Can you inform me how to make a large negative from a small one?"—Make a transparency from the small negative, either by contact printing on a dry plate or on carbon tissue, and from that make the negative the size desired in the enlarging camera. Any elementary work on photography will give the working details. We should have thought the firm on whose memo paper you put the paper would have given you the desired information.

STAINED NEGATIVES.—J. C. DUNK. The occurrence is by no means uncommon with much-under-exposed plates when they are much forced in the development and a large quantity of ammonia is used, as in your case. The stain is exaggerated if the dark-room light is not perfectly safe, and the negative is frequently examined by it. So it is if, between the development and fixing, it is exposed to white light. Nothing can be done to improve the negatives now except by reproducing them; then, if all the detail is there, quicker printing ones may be obtained.

INSTANTANEOUS WORK IN WINTER.—THOS. WADE. The quickest lenses for winter would be the portrait combination, of which there are different grades of rapidity. The quickest series is that known as "baby lenses," and have an aperture of nearly *f*-2. The next is the *carte* series, with an aperture a little less than *f*-3. The ordinary portrait lens comes next, with an aperture of about *f*-4. All these lenses are bulky for the size of plate they cover, and have little "depth of focus" when worked with the full aperture. Still, they are useful tools when rapidity is the main thing to be considered.

PHOTOGRAPHING BY ARTIFICIAL LIGHT.—B. & Co. write: "We have the opportunity of taking photographs of a very important meeting to be held in the Town Hall here. The Hall is lighted by half a dozen arc lights, and, from experiments we have made, we anticipate no very great difficulty, except in one corner, which the light does not fairly reach, and it is here that some of the most notable people will be. Can you give us a hint or two?"—If it is impossible to add temporarily another arc light to illuminate that portion of the building, the only thing we can suggest is to use a flashlight at the end of the exposure, directing it by a reflector in the direction required. If you adopt this plan, take care to intimate to the meeting what is going to be done, or the flash might create a panic in the building, with serious result.

YELLOW STAIN.—E. J. W. says: "During the last fortnight I have toned three times, and each time about a quarter of the prints have had a yellow tinge on them; the treatment has been exactly the same as previously using Ilford formulæ. Can you suggest a remedy? Would the damp weather be the cause? I enclose photo showing the defect?"—It is difficult to say the cause without seeing the work carried out. As a fourth of the prints only are stained, it is clear that it is not the fault of the paper; hence, it must be due to the manipulation, but in what way it is impossible to say. Possibly it may be the use of too weak a solution of hyposulphite or too little of it; or the prints, not being kept in motion while in the fixing bath, may account for the trouble. We do not suppose the damp weather has anything to do with the trouble.

SPOTS ON ALBUMEN PAPER.—PERPLEXED writes: "Will you please tell me what you imagine to be the cause of black (apparently metallic) spots on enclosed sensitised paper. I have been greatly troubled with them lately. They do not appear on the paper at all till after it is sensitised and before it is printed. The sensitising room is kept as free from dust as possible. Do you think it is caused in any way by the blotting-paper used after paper has been floated? By giving your valuable opinion on the matter you will very greatly oblige."—The spots are due to reduced silver. Metallic particles in the paper itself would produce similar spots, but these are not due to that cause, as they do not show strongly enough on the back. They appear to be rather due to a particle of some pernicious matter coming in contact with the albumen surface after it is sensitised and while wet. Dust from sulphate of iron, pyrogallic acid, or similar reducing agents, would produce similar spots, so would metallic particles in the paper with which the albumen surface is blotted. We should advise a change in the blotting-paper. Get a sample of chemically pure paper from some of the operating chemists. Commercial blotting-paper is rarely suitable for photographic purposes. Marion & Co. supply an excellent blotting-paper.

EX CATHEDRÂ.

The Research Fund of the Photographic Convention of the United Kingdom has so far not been availed of, and the scheme seems virtually a dead letter. There is a feeling that this is due to the fact of the rules governing the administration of the Fund being unsuitable. At present, application for a grant in aid has to be made by the person proposing to take up a certain line of work, and, though in theory this arrangement seems a good one, there are cases in which a natural reluctance to make application will render the rule unworkable. We believe the Convention executive is to be invited to amend the rules relating to the Research Fund so as to place in the hands of the Council the power of making bestowals of grants, instead of waiting for applications. By giving the Council a free hand in this matter, it is felt that the scheme will work more satisfactorily than hitherto.

* * *

As already announced, the Annual General Meeting of the Photographic Copyright Union will be held on Thursday, October 8, at eight p.m., at St. James's Hall (French Salon). The entrance is in Piccadilly. We hope that a large number of members will attend and demonstrate by their presence their interest in so useful a Society as the Copyright Union.

* * *

A pleasant reminder of the Leeds Convention reaches us from Messrs. Wellington & Ward, of Elstree, who send us a number of photographs of Bolton Abbey and York Minster. These were taken by Mr. Wellington himself. The prints, which are excellent, are on the firm's matt bromide paper. The chief point of interest, however, lies in the fact that all the negatives (which, with so able a worker as Mr. Wellington, are, it is needless to say, of exceptionally good quality) were taken on negative bromide paper. Critically examined, the definition appears to be exceedingly crisp, which is a strong point in favour of the paper; indeed, but for the knowledge that negative paper had been employed, it would be difficult to tell that the beautiful views of York and its fine old Minster were not made on glass plates.

* * *

Our daily correspondence indicates the existence of so much interest in the alleged discovery of photography in natural colours by Mr. J. W. Bennetto of Newquay, that we here give an account of the present position of the controversy. It may be remembered that a fortnight ago the subject was extensively referred to in our columns. We criticised the test to which Mr. Bennetto had been subjected, and not only termed it unscientific, but doubted the qualifications of the Committee appointed to conduct that test and to judge of the results. The last number of our Newquay contemporary, while making other extracts from our columns, overlooks this criticism, and takes occasion to "regret" that we did not accept a strange challenge that was made to us, and that has absolutely no bearing on the question whether Mr. Bennetto has, or has not, discovered photography in natural colours.

* * *

An old contributor to these pages, Mr. G. R. Baker, writes to our contemporary in a favourable strain of the quality of Mr. Bennetto's projected transparencies, and characterises the results as beautiful. We obtain no clue, however, as to the details of the process. The mere inspection of coloured lantern slides projected on to a screen is not sufficient to validate the remarkable claims that have been made by and on behalf of Mr. Bennetto. The very latest development of matters is to

be found in the letter, a copy of which we append, that was addressed to us personally.

* * *

The writer, Mr. A. Bluett, of 3, Dereham-terrace, Truro, says: "Mr. Bullmore tells me that you have shown some interest in Mr. Wallace Bennetto's alleged discovery of colour photography. As representative of the *Western Daily Mercury*, I have made an appointment with Mr. Bennetto to see his productions on Monday evening. Perhaps you will consider it worth your while to ask one of your representatives to meet me in Newquay on Monday with the idea of our making a joint *investigation*."

* * *

To this courteous letter the following reply was sent: "If you are to have an opportunity of examining the photographs in natural colours, and of witnessing and having explained to you the actual process by which Mr. Bennetto produces his results, I have no doubt that either Mr. G. G. Bullmore, of Newquay, or Mr. F. Waren, photographer, of the same town, would be pleased to join you on my behalf. Will you, if necessary, present this letter to one of those gentlemen? If, on the other hand, you are simply to witness a series of projected transparencies, no useful purpose can be served by my being represented."

* * *

We continue to receive copies of West of England newspapers, and communications from other sources, containing descriptive accounts of the beauty of Mr. Bennetto's transparencies in "natural colours;" but we look in vain for any information bearing upon the details of the process by which these results are said to be obtained. Until that information is forthcoming we shall maintain an attitude of what Mr. Bennetto himself has termed "reasonable scepticism" towards claims which, however persistently urged and reiterated, are at present lacking in the not unimportant essentials of independent verification and substantiation.

* * *

Mr. E. Cecil Hertslet, a well-known member of the Royal Photographic Society, upon the Council of which he was elected some few months ago, has received the appointment of Consul General of Her Britannic Majesty at Havre, France. While we congratulate Mr. Hertslet upon his appointment, we shall be sorry to miss his presence at the Society meetings, at which he was a regular attendant. He will leave this country in the course of the next few weeks.

THE CARRIAGE OF PHOTOGRAPHIC GOODS.

A letter which we recently published from a correspondent who had, he believed, a cause of complaint against a railway company for damage to a parcel of plates has led us to make some inquiries to enable us to put before those of our readers who have not much experience of the commercial aspect of photography, some useful information on the subject. Many of the railway charges seem exorbitant and often unjust, which, upon explanation, may prove to be both just and reasonable.

We will take, at the outset, the particular case in question. There is first to be considered which is the aggrieved party when damage is done? It is generally understood that, if a claim lie at all, it is by the person who makes the contract, and that is assumed to be the one who pays, or is to pay, the carriage. The next point is, When a claim can be made. This depends upon the way the goods were delivered to the company. The carriers have two classes of charges for most goods—goods carried at owner's, and those carried at sender's risk—the latter being considerably cheaper than the former. The essence of this understanding is that, when the carrying is at owner's risk, no claim can be entertained unless there is clear proof of improper treatment by the carriers; and there is rarely any clear enough case of the kind, unless the package bears external marks of violence, in which case there is little doubt that the company interested would make good any injury to a package or its contents, if it could be shown that they left the sender in good condition.

When the carrying is at company's risk, any damage that the goods receive may be claimed for, if it can be shown, without reasonable doubt, that the goods left the sender in good condition and properly packed.

There is an important point to bear in mind. There are about seven different classes into which goods are divided by the railway authorities (and it may be noted that all have the same rules and the same classification), and it is most desirable that, when the contents of a case or other package are of a fragile character, the fact should be notified, for in the case of a breakage all redress would be refused, and justly, if the goods are of a more risky character than they are declared to be. We believe it is a common practice with many, when sending single glass pictures, or a few negatives, by passenger train, to omit marking the wrapper with the word "glass." This involves an increased charge of twenty-five or fifty per cent., so the risk is taken; but, if there be damage, and there be no indication of the nature of the contents, no claim for damages will lie, because the carriers were not warned, and so took no extra precautions to ensure safe carriage.

We have spoken of sending by "passenger train;" there is, however, another mode, namely, by "goods train," and many people are puzzled as to what the difference is. It consists mainly in the facts, firstly, that there is usually only one goods dispatch in the day, while passenger-train parcels go by almost every passenger train during the day; and, secondly, goods dispatch is usually cheaper. It is, indeed, considerably cheaper for large parcels; but there is a fixed minimum charge, which may exceed the passenger-train rate for parcels of few pounds' weight only, and it is in such circumstances that complaint of over-charge is often made. Further, a consignment may often take twice as long to deliver by goods dispatch as by passenger.

Some of the differences in practice may here be noted. The railway companies require an invoice delivered to them for goods, but not for passenger parcels; and, so long as a recognisable distinctive mark is placed on the cases, it is immaterial whether they are addressed or not, so long as the invoice contains the address for "goods." Again, when several packages of a kind are sent at one time to one consignee, their united weight only is charged by goods dispatch, while with passenger parcels each parcel or packet is charged separately.

It may have been noted that, when questions of claim for damage arise, both services are alike in the fact that no claim is allowable without insurance if the consignment exceed 10*l.* in value, unless under certain exceptional conditions.

Insurance varies from sixpence to half-a crown for 25*l.*, value according to the nature of the articles. From them we may

extract negatives which come under Class II.; pictures and paintings, and "glass of all kinds," except certain special articles, Class III.

There is, finally, the question of "empties" to be considered, and a subject that is frequently the cause of much heartburning and annoyance. Primarily, the sender of an empty has to pay the company, but sometimes, to regular customers, they will consent to claim the carriage from the consignee. If, however, he is unwilling to pay, he should simply decline to do so, and refer the carrier to sender. Carriers have a lien upon goods for the value of the carriage charge, but, as empties are often of little value, they prefer the system of requiring the sender to pay. It may be noted, as a very vexatious system, that for empty crates, so often used by photographers for parcels of frames, &c., the companies make besides a minimum charge of one shilling, whether the distance be small or great.

We think we have now exhausted all ordinary questions, and we trust our readers may find our compilation of some practical benefit.

The National Gallery.—From last Sunday, it is announced, the National Gallery and the National Portrait Gallery will be closed on Sundays during the winter months. A special meeting of the Sunday Society was held on Saturday to memorialise the Trustees on the subject. The reason assigned for the Sunday closing for the winter is the absence of artificial light in the buildings. Although the attendance at both Galleries has been good since the Sunday openings, we doubt if the Trustees will consider that it has been sufficient to warrant them in installing artificial light simply for Sunday visitors during the winter months, the more especially as they did not take altogether kindly to the project in the first instance.

Shutter Patents.—We have been asked several times during the past few weeks to express, in the Answers column, opinions as to the originality of shutters, descriptions of which accompanied the queries. Of course we have declined, as we always do, to give opinions on such points. If we did so, it would involve an immense amount of research at the Patent Office. It may, however, be interesting to our readers, especially to those who have written on the subject, to know that reference to the "subject-matter" index at the Patent Office shows that, during the period 1885-91 inclusive, no less than one hundred and thirty-seven patents in connexion with photographic shutters were taken out. This is exclusive of the provisional protections which were granted and the patents not completed, or the descriptions of others in the journals, and for which no patents were sought. In the seven years named, the number of patents mentioned above were actually sealed.

Process Block Illustrations.—Our facetious contemporary, *Punch*, has always been noted for the excellence of its illustrations, as well as the artistic merit connected with them. The drawing of the current artists—Tenniel, Du Maurier, and others, as well as J. Leach and others in the past, are evidence of that. A few weeks back *Punch* made a new departure, and introduced two or three half-tone process blocks from wash drawings, amongst its other, and old-style, illustrations. The contrast was striking. How they were appreciated by the readers, it is, of course, impossible for us to say; but, as this style of work has not appeared since, we conclude that it was only introduced as an experiment. If our contemporary intends, successfully, to adopt half-tone process blocks in place of its well-known sketchy line illustrations, it will have to adapt its printing department—machines, paper, ink, &c.—specially to suit that class of work, to say nothing about the artists' original drawings.

Exhibition of Miniatures. — The Society of Miniature Painters, to which we referred a few weeks back, has opened its inaugural Exhibition at 175 New Bond-street. Photographic portraitists will do well to pay it a visit to see what is yet possible with miniature painting. There are some two hundred and fifty exhibits, some of which are of exceptional merit. Although there are not any Cosways, Shellys, Collinses, &c., there is sufficient good work, including that of some by R. A.'s, to prove that miniature work is by no means the lost art that some have imagined. Photography, and the high-class coloured photographs once obtainable, no doubt, killed miniature painting or, at least, that of the "Miss La Creevy" type; but what, it may be asked, caused the practical demise of the high-class coloured photographs which have now become as rare as miniature paintings?

The British Association. — The 1896 meeting of the British Association is now a thing of the past. At Liverpool nothing relating especially to photography took place, nor has photography, except as an adjunct to other matters, figured at any of the meetings for some years past. We were somewhat surprised that the metric system of weights and measures did not find the support we should have expected it would from a scientific body. We expect that not much of real value is to be accomplished at the meetings of this Association. It is practically a fashionable pleasure outing, and "science and learning" are an excuse for holding them. It is true that papers are read, and others are taken as read, but, in a sense, the meetings are very much like those of the Photographic Convention — excursions are generally better attended than the meetings. The next meeting of the Association is to be held at Toronto, under the presidency of Sir John Evans.

Processes at the Exhibition.—The annual Exhibitions of the Royal Photographic Society are generally looked upon as indicating by the pictures shown, and the printing processes by which they are produced, the direction in which photographic taste and ideas are running year by year. With regard to the processes, they must by no means be taken as indicating what is being done commercially in photography. This year there are 346 frames shown, as against 459 last year, roughly a hundred less—practically one-fourth less. This year there are, according to the catalogue, when the process by which the pictures were made is mentioned, 146 platinotypes, as against 176 last year, practically the same proportion; in carbon, 92, as against 110, a slight increase; bromides, 27—last year there were but 26, hence there is a material increase in them. Last year there were 41 gelatino-chlorides, but this year only 8. Of "silver," which are supposed to include albumen, "platinum-toned," and other silver methods, not including gelatino-chloride and bromide, there are 13 as against about double that number last year. There is a very marked falling off in photogravure exhibits. Last year there were 22, while this year the number can be counted on the fingers of one hand, and yet have some to spare.

As mentioned above, the proportions of processes one to the other, as represented at the Exhibition, must not be taken as at all showing what is done commercially in every-day work. In the Exhibition the largest proportion of the work is in platinum, and next comes carbon, while gelatino-chlorides and "silver" are but feebly represented; yet we know that each of these methods is far more largely worked than are the other two put together, and the makers of these different papers tell us that the sale of them was never greater than it is now. Collodio-chloride is not even mentioned in the catalogue, but every one knows that that is now commanding a large and increasing sale. Bromide, again, figures less prominently than platinum in the Exhibition, but the quantity of the former paper used, as against the latter, is immeasurably greater, so, also, in the case of carbon, where the difference is still greater. We mention this as, from the catalogue, foreign photographers and those in out-of-the-way places in this country might imagine that the ordinary methods of silver had almost become extinct in this country.

DIGRESSIONS.

X.—From a Window at Broadstairs.

At this delightful little watering-place, between Margate and Ramsgate—yet not of them—are three objects, beloved by photographers as subjects. One is an arch, in a narrow street going down to the harbour; the next, not far off, is the jetty and the boats; and the third, the little curved bay, with its fringe of tents under the cliffs, its bathing machines, niggers, the photographer who, by the courteous manner of his touting, makes the lower rank of the profession honourable, and the holiday crowd, always there in the season, from early morn till dewy eve, no matter the state of the tide. This foreground is backed by the picturesque part of the town, the jetty, and the harbour, surmounted by Bleak House, which was once the home of Charles Dickens. This charming view is seen from the terrace on the edge of the cliffs, which does duty as a promenade. On this terrace is a handsome band stand, in which plays, much too often, a by no means proficient town band. This, I hear, is to be remedied. In the intervals of exhaustion of the band, the musical riot is continued by barrel-organ fiends. My window is near the stand, and, as I write, I confess to wishing that, when "Music, heavenly maid, was young," she had gone for a bathe, and got out of her depth.

But everything has its compensations, good or bad, and my window looks out upon the standpoint, on the terrace, from which the grand view of the place is to be had, and affords me much to cogitate upon. It shows me these curious and gratifying facts, among other things: That the new boom in cycling has not quite extinguished amateur photography; that hand cameras do not yet equal stand cameras in number, at which I am surprised; that 10 by 8 and whole-plate cameras are still used, but sparingly; that the half-plate is not so popular as it was; and that the average number of those who take this particular view, at this time of the year, is about a daily dozen. One day I counted twenty-three, and there must have been some who escaped my notice.

The methods of working vary as curiously as did Garrick's face when he sat to Gainsborough, but there are few exceptions in the practice of the photographers in one important particular, nearly all show that excessive care and fidgetiness which come from doubt and want of knowledge.

Our view is an obvious picture; there is very little to choose about it. It is difficult to make a mistake in selection. Yet few are able to "see" it at once; and none appear to have that assured confidence which enables a man to "come, see, and conquer." Many put up their cameras on their stands as if they enjoyed dallying with their apparatus, look at the focussing screen, shift a foot or two (or perhaps a few yards), are very careful to get the right amount of foreground, still more careful to see that the camera is level (by instrument), consult a friend, adjust the shutter and the stops, and then give it up and go away. All this trouble is part of the holiday, but confidence does not run to the price of a plate. They come again another day, and go through the same performance. I have seen one man do it four times. The last time he did venture to expose, then out came the note book, and the whole history of the case was written down.

Now, I like a photographer to think over his work, but I do not care to see him puzzled, fuddled in thought, for want of knowing how to think, or apparently wanting in knowledge of how to use his material for thought. The artist will see his picture without any reference to his camera, until he wants it for use, and only looks at the ground glass to make the necessary adjustments.

I mentioned the note book. This taking of notes is very praiseworthy, if it is not carried too far and made to interfere with essentials, but it is the second barrel that often brings down the bird, and this opportunity is sometimes lost in writing down the true and particular history of how the first shot was missed. A photographer once showed me a large volume in which the whole history of every plate he ever exposed was carefully entered on business principles. This was the ledger into which the day book was posted. It was as particular and minute as Pepys' *Diary*. (How that learned F.R.S. would have revelled in photography! He would surely have spent another annual guinea, and become F.R.P.S. as well!) My friend was more proud of this book of his than of anything else he had ever done, and rightly. It was a monument of patient, if useless, industry; it was the best of its kind. His photographs were never known to exceed the "usual thing."

Before leaving our bay as seen from the terrace, I should like to mention that one of the most lovely sights I know is this view as seen in the gloaming on a suitable evening. It is a fine example of what is meant by the word "tone;" of the variety and harmony there can be in greys. The jetty is the dominant note; it is a picturesque mass, jutting out into the sea, tarred, and therefore black, but put up your hat before it, and you will find that distance and the fading light have etherealised the black into a lovely dark, rich purple colour, surrounded by the varying yellow greys of the sea, in which are streaks and masses of cold blue; the sky has been of a cool grey tone, but is now turning to a misty warm grey over the horizon. The powerful dark of the jetty is repeated, but of a greener tint, in the trees mingled with the warm brick houses of the town, the lighter cool grey of the chalk cliffs gives value and breadth; Bleak House, an ordinary brick building in daylight, seems in the fading light like a grand mediæval tower protecting the harbour, and the fine breadth of life-deserted sands, with their beautiful pattern of seaweed fringing the margin of the tide limit, repeats and echoes the numberless tones of the rest of the picture, and completes the harmony; and now, as the evening deepens, the half moon becomes visible in the south-west, and the jetty lights appear. The dying after-glow throws a mellow tone over the effect and gives a fairy-like aspect to the scene.

I don't know if this is photographic. I have not tried a plate upon it, because I have not quite mastered the two-years'-studied time arrangement of my camera, but if you will seek the causes which produce such effects, and try to appreciate them at their artistic worth, you will become a better photographer.

Others of those who entertain me unawares have their own peculiarities. Some are content with a view-meter, or a brilliant finder. Last week one seemed to be exposing a long time, and curiosity led me to run down from my observatory to see what he was doing. He was photographing a holiday crowd with a pinhole! I ran away for fear of being offensively hilarious. I know there are those who believe in the formula *f*·64, $\frac{1}{100}$ *s.* (I regret I have forgotten the H. & D. number), for snap-shots in a dark cathedral. How can you catch the fleeting smile of the marble angels if you are not quick? Perhaps it was Mr. Nicholson, whose brilliant imagination conceived *The Cricketer* last year, and whose skilful fingers executed it. He must have been working for the Salon. I could easily believe this to be his method. He looked like a humourist.

With the exception of this last, the prevailing characteristic of the holiday photographer is certainly "doubt." He dreads bowling wides and no balls, and will take no risks on the off chance of getting a wicket. He seldom seems to know when he has got a subject, still less does he know what to do with it when it dawns upon him, possibly because our view is not a church, a castle, or other bit of architecture. One of the other of our three subjects is much more patronised. This is the arch. This arch is neither picturesque nor particularly interesting, architecturally or historically, but it is an "object" of the familiar kind, and he is safe. It spans the street leading to the harbour, and I never go through it without getting in the way of a photographer.

One day I ventured to open a conversation with one of these "bold camera-wielders," as the scoffing Gleeson White, who "sins against knowledge," calls the much critic-enduring photographer. He had more workmanlike tools, and seemed more experienced, than the others; still, he appeared to have much difficulty in making up his mind. I was glad to find he had practised our art in the "wet" days, and had never severed the continuity. He seemed pleased to show that, though an old photographer, he was up to date. He told me that he still attended lectures on the science at a great institution. He gave me the names of his teachers; they were all scientists. He talked to me of things as connected with photography of which I knew nothing—eclipses and Röntgen rays, as well as of the brilliant defining power of the latest developer on which his Professor had lectured, and he seemed to know an unreasonable lot about

lenses, of which he carried a battery; but he had never thought picture-making worth a lesson, although picture-making was his object.

There ought to be a moral, and I think it is clear. This *doubt*, with which most photographers are troubled, comes of ignorance. They are full of knowledge up to the throat, but of a useless sort, very little indeed of the kind being required on the mission on which they are bent as they roam the country. Their object may not be to produce the highest class of work, but they certainly desire to make their photographs as like pictures as possible; yet they study almost everything systematically, except the one essential—picture-making—and cannot *see* a picture even when the materials are hitting them in the eye.

As I have hinted above, there is one part of my present camera that I don't understand, but which is a source of perpetual intellectual diversion to me. The study of it is as interesting, and about as useful, as endeavouring to learn art from photographs without any aid from books or other teaching, as recommended by a scientific lecturer connected with the Royal Photographic Society a few months ago—a method which was actually backed up by one or two other scientists, which possibly may let some light on to the quality of their results—when any.

Besides all the other ingenious contrivances in my camera is an arrangement for time exposures. Time exposures with a hand camera are not likely to be of very much use to me; but I am so far a scientist that I like to "know you know" to a moderate extent, and in leisure moments rejoice in a knotty problem, if it is not too absurdly useless, as many of them are. The proper working of this time exposure depends upon the exact position and relation to each other of two little knobs or balls, which in the printed directions are called H and O, as if they were two of the elements. They have to revolve round each other, while something else is looking the other way; the rest of the drama takes place inside the box, where you cannot see what goes on. It happens that mine is one of that remarkable kind of cameras which shake themselves together and are born again every January 1, and become the pattern for the next year—an ingenious business renaissance which makes cameras second-hand before their time. Now, it is unfortunate that my camera and the "book of the words" I possess were not born in the same year, so that when the "directions for use" call the tune the knobs won't dance, and, as I have said, I have here a source of continual enjoyment which was not charged for in the price of the camera, and will last me all the camera's life, which I am afraid won't be long, yet I have a sentimental objection to seeing it become second-hand.

If sound could be blended with printed words, there ought to be found the mingled harmony of the following noises running through these lines: the prevailing "music" from the band stand under my windows produced by a shrill piccolo and a badly played and intermittent ophicleide; the sweet melody of the "intermezzo" on the barrel organ, of which I have had three weeks on end; the sleepy swish of the waves as the calm tide comes in; the rustle and drowsy hum of the crowd as they pass my window; and all this not without a slight sensation of the whisper of horror that runs through the holiday promenaders as the remains of the man who fell over the cliff are rowed across the bay to the landing-place.

H. P. Robinson.

THE TREATMENT OF OVER-EXPOSED PRINTS.*

For the purposes of this method the over-printed proofs should be well washed and fixed in fresh hypo, and again thoroughly washed. For bleaching, a weak solution of bichromate of potash, to which a few drops of hydrochloric acid have been added, is preferable to either cupric, ferric, or mercuric chloride, though these may be used. In any case a very thorough washing should be given before redevelopment, and the prints should not be unnecessarily exposed to strong light. A certain amount of exposure is necessary in order to secure the tone on redevelopment, and it is on this account that the chromic salt and hydrochloric acid treatment is preferable to either of the others, since it forms an image in pure chloride of silver which is capable of rendering a faintly visible image on exposure to light. In the other cases the presence of other matters in conjunction with the silver chloride renders the formation of a visible image a matter of uncertainty, and in the case of mercuric chloride an impossibility, while the foreign matter also has a bad effect on the subsequent tones.

Let the proofs be exposed to diffused light until the picture is faintly seen in all its details, and then proceed to develop with the usual developer recommended for partially printed-out proofs. The one I have found to answer for all general purposes is that given by the Eastman Company for use with their printing-out paper, and consists of hydroquinone with a large dose of soluble bromide, but I omit the tannic acid as a useless complication. With this solution the picture is redeveloped in a very gradual manner, appearing, in all its details, very faintly at first, and slowly gaining strength; its progress can be stopped when the proper point is reached, and after a very thorough washing, an acid bath being used, the print can be toned and refixed along with others.

Of course, this is a somewhat troublesome and roundabout way of procedure that possibly only extraordinary circumstances would justify; but the next method I shall give, which is entirely new, possesses the advantages of extreme simplicity and of giving tones at least as good as, and in some cases superior to, those obtained in the ordinary manner. It is based upon the use of a bleaching or reducing solution that is also to some extent a toning solution, which reduces the over-printed image to the desired point without removing it altogether, and at the same time partially tones it, leaving the rest of the work to be done in the ordinary bath. The treatment, in fact, consists merely in immersing the print in the reducing solution until it reaches the required depth, and then, after washing, toning it in the usual way. The results, even from apparently hopelessly over-printed proofs, are in no way distinguishable from those obtained in the regular way.

The reducing solution consists of a platinic salt; I have used the chloride chloro-platinate and also a solution in which the platinic salt had been imperfectly reduced in making the chloro-platinite. It will be remembered that Mr. Lyonel Clark some years back, in describing his platinum toning process, pointed out and explained the reason of the reducing effect of platinic salts when employed for toning purposes. Every atom of platinum deposited on the prints from solutions of those salts displaces four atoms of silver, and consequently, unless a very strong silver image exists in the first place, it suffers almost complete removal during toning. When the platinous salts are used only two atoms of silver are replaced, hence the employment of the chloro-platinite of potassium.

Thirty or more years ago, bichloride of platinum was occasionally used, but, even in those days of dense, hard negatives and strongly silvered paper, its reducing power prevented its general use, but I do not recollect that it has ever been proposed to take advantage of that power, and it was only when employing a platinum bath in which the salt had been imperfectly reduced, and therefore containing a certain or *un*certain proportion of platinic salt, and, noticing that some over-printed proofs were the only ones that passed the ordeal with even moderate success, that the idea suggested itself of putting the reducing action to a practical use. Having done so, I can report upon its perfect, and, I may say, unqualified, success.

Briefly, the method I have adopted is as follows: I have selected the bichloride of platinum as being the most generally useful salt, and of this I add one grain to five ounces of a saturated solution of common salt to form the reducing solution. This may be kept as a stock solution, and, so far as I can see, does not undergo any change, except from the gradual exhaustion by use, as is the case with the gold toning bath. The prints to be treated are just washed along with the others to remove the free silver, and then immersed in the reducing solution until brought down to the proper stage. The same precautions require to be taken as in toning to secure uniformity of action, but the colour of the prints in the reducing bath forms no part of the calculation, and must be disregarded. With some kinds of paper, a decided toning action takes place before reduction occurs, especially when the degree of over-

* Concluded from page 612.

printing is considerable, but in others no change at all occurs unless it be a reddening.

The reduction must not be carried too far, for it must be borne in mind that the gold bath will still further bring the prints down; indeed, I think, to a greater extent than when the platinum bath has not acted, and this further action must always be allowed for; and that forms the only point in the process that requires the least care. The precise allowance varies with different makes of paper as well as with different degrees of over-printing; but these little points are soon mastered, and the whole process becomes one of the greatest simplicity and certainty. After the reducing bath, the prints require to be thoroughly washed, to removed acidity and also the excess of salt, and may then be toned along with the rest, though they will require special watching, as they tone much more quickly. The sulphocyanide and phosphate baths are those that have given the best results in my hands.

Those who are troubled with over-printed proofs will find this last method a great boon, as it requires no special preparation after the solution is made, and by its means prints that are so dark as to be barely distinguishable can be made to give as perfect results as if printed to exactly the correct depth. W. B. Bolton.

ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

As we predicted last year, the method of formally inaugurating the Exhibition by a private view in the daytime, as well as by a conversazione in the evening, was maintained on this occasion, and on Saturday last the gallery at Pall Mall was in a more or less crowded condition all day. The attendance at the private view, in spite of drizzling rain, showed no signs of falling off, while the *Soirée* attracted over a hundred more visitors than on any previous occasion, some five hundred and fifty members and friends being present in the evening.

In the unavoidable absence of the President (Captain Abney), who has called down into the country on urgent business, and of the Hon. Secretary, Mr. Chapman Jones, who is suffering with influenza, the Society's guests were received by Sir Henry Trueman Wood (Vice-President), Mr. G. Scamell (Hon. Treasurer), Mr. E. Clifton (Librarian), and by Messrs. Bolas, Bridge, Cadett, Cembrano, Debenham, Hertslet, Hollyer, Mackie, Marchant, Sinclair, Spiller, Wall, and Wilmer.

Among those present we noticed the following:—Mr. H. L. Ashton, Dr. and Mrs. Acworth, Mr. E. R. Ashton, Mr. and Mrs. W. E. Asquith, Mr. Smedley Aston, Mr. and Miss Avent, Messrs. Bernard Alfieri, H. W. Bennett, Agar Baugh, Frank Brown, L. M. Biden, F. W. Brook, Mr. and Miss Bickerton, Mr. E. E. Barrow, Mr. and Mrs. F. A. Bridge, Messrs. Bingemann, C. and A. Bayne, Braun, A. E. Brown, W. A. Bagley, W. Barry, F. O. Bynoe, Birt Acres, Grayatone Bird, T. Bolas, C. Beadle, Redmond Barrett, Algernon Brookes, Mr. and Mrs. Cembrano, Messrs. A. J. Campbell, J. Carpenter, F. B. Cattley, F. N. Clark, F. T. Carter, Edgar Clifton, C. Coleman, F. A. Crew, B. Cox, Page Croft, Mrs. Cole, Dr. McDonald, Mr. Sebastian Davis, Mr. Herbert Denison, Messrs. F., Charles, and W. E. Debenham, Mr. and Miss Drage, Messrs. H. E. Davis, P. Everitt, H. J. Ellis, H. C. Everson, E. H. Fitch, A. Fisher, A. H. Fisher, E. W. Foxlee, J. T. French, A. Fellows, C. H. Freeman, T. Fall, S. H. Fry, E. Fuchs, J. Fuerst, T. E. Freshwater, Mr. and Mrs. Gerard, Messrs. J. Guardia, A. J. Golding, Geard, G. Gosling, H. D. Gower, J. Gunston, J. H. Gear, Hirst, W. E. Henry, A. P. Hoole, A. S. Handford, A. L. Henderson, Mr. and Mrs. E. Cecil Hertslet, Messrs. Holt, Howard, A. S. Newman, W. Jones, G. H. James, F. E. Ives, F. W. Jackson, A. J. Jones, H. Jeula, A. J. Johnson, L. de Jonquieres, J. J. Vezey, Klosz, P. King, Rev. F. C. Lambert, Messrs. C. B. Lewis, R. B. Lodge, H. G. Moberley, Monnickendam, W. M. Ashman, H. A. Morrison, R. Y. Murphy, H. Maclean, E. Marriage, Mr. and Mrs. J. C. S. Mummery, Messrs. L. Matthews, Paul Martin, H. T. Malby, F. W. Muncey, Mr. and Mrs. Fred Marsh, Messrs. E. R. Mattocks, S. F. Morgan, W. Martin, A. Mackie, S. C. Mote, J. Nesbit, D. J. O'Neill, S. W. Owen, J. H. Oliver, C. H. Oakden, W. L. Opie, Major and Mrs. Prendergast, Messrs. R. B. Pyke, A. F. Penraven, W. A. Palmer, F. L. Pither, Mr. and Mrs. E. E. Pither, Mr. W. H. Prestwich, Colonel and Mrs. Palmer, Messrs. H. C. Rapson, Ray, A. J. Rayment, J. L. Russell, W. Rawlings, Mr. E. J. and Miss Richards, Messrs. F. W. Renant, H. Smart, E. Swingler, E. S. Shepherd, C. Stuart, O. Sichel, H. Stuart, J. Stein, T. A. Scotton, C. H. Smith, Claude Spiller, Mr. Arnold and Miss Spiller, Mr. and Mrs. E. Scamell, Messrs. Sanford, Illingworth, Swift, Slater, H. Smith, C. F. Townsend, John Spiller, A. F. Taylor, W. Taylor, G. Taylor, H. Taylor, R. F. Thompson, F. C. L. Wratten, Mr. and Mrs. S. E. Wall, Messrs. R. C. Williams, C. E. White, Mr. and Mrs. J. B. B. Wellington, Messrs. H. Walker, J. Webster, W. T. White, Charles White, Walford, Woolnough, Watmough Webster, J. R. Williams, T. R. Wright, Allenstein, Yardley, and Zachariasen.

The Judges.

The Judges at this Exhibition were Messrs. Cembrano, Gale, B. W. Leader, A.R.A., G. Storey, A.R.A., and W. L. Wyllie, A.R.A., in the Art Section; while, in the Technical Section, Captain Abney, Mr. A. Pringle, and Mr. Chapman Jones adjudicated. The awards of these gentlemen, if not exactly those which we should have made ourselves, are at any rate free from the eccentricities which we have occasionally found it necessary to denounce in bygone years, and seem, on the whole, to give satisfaction all round.

The Hanging.

On entering the gallery, we were struck by the altered appearance of the room, which, by the side of past exhibitions, with their huge frames piled from the floor to the ceiling, looks somewhat empty. The reason for this is twofold—the fashion of framing up close, which is fairly rampant this year both at Pall Mall and at the Dudley Gallery, and the fact that the selection has been much more rigorous. We were informed that over 1100 photographs had been submitted to the Selection Committee, of which 353 are upon the walls, or less than one-third of those sent in; and the thoroughness of the selection may be realised when we say that it would be difficult to point to a dozen frames which it would improve the Exhibition to omit; in fact, with hardly a single exception, meretricious work is conspicuously absent. Moreover, this year the walls have been to some extent split up into panels by means of drapery, and the groups of pictures so made selected so as to harmonise with one another. The extent to which this has been carried is so great that practically all the photographs on light-coloured mounts are to be found in two small groups, the appearance of the remaining divisions being vastly improved by the absence of the spottiness such frames create when mixed with darker work. The apparatus has been kept to what is generally regarded as the "technical" end of the room with advantage, and the general effect is to greatly increase the apparent size of the gallery. The hanging, as far as we could gather on Saturday, met with general approval, one visitor declaring it to be the best hung exhibition he had ever seen, but this assertion is perhaps too sweeping. Any how, a change for the better has been made, which we trust will be maintained, and the selection has been carried so far as to make the admission of a picture to the Exhibition an award in itself. The emptiness of the upper portion of the walls and the removal of the apparatus table has the effect of revealing the extreme shabbiness of both carpet and wall-covering, and, since the Society is mulct in the amount of some 170*l.* for rent alone for the Exhibition, it is high time their landlords recognised the necessity for putting both on a better footing.

The Pictures.

It is as well to say at once that the Exhibition contains no work which, by reason of its striking super-excellence, stands out head and shoulders above its surroundings. On the other hand, as we have said before, it is singularly free from rubbish, and hardly a picture is on the walls which will not repay careful attention. To start with the awards,

The Medalled Pictures.

No. 38, *A Study*, by Phillip von Schoeller, is one with which almost every one will agree. A portrait of a girl in a dark cloak and cap, with a white ruff round her neck, it is one of the most pleasing pictures in the Exhibition, and possesses a softness and delicacy which is well worthy of emulation. It is printed by the Artigue carbon process. The other portrait by the same exhibitor, No. 45, *A Tyrolese Peasant*, is hardly of such good quality, and is a little crude, but is still distinctly high-class work. Mr. J. Bushby takes a medal for No. 57, *Trau Cathedral, Dalmatia*, an interior of a singularly "pencil" like texture. Another of his exhibits (No. 82), *Gipsies, Herzegovina*, is an excellent example of grouping, but suffers severely by the method of printing adopted, red carbon on opal, which robs it of much of the vigour which would be well placed therein. *Oxen Ploughing* (No. 118) is a much more satisfactory print to our mind, but Mr. Bushby's No. 252, a heron or other long-legged bird in a pool, presents possibilities rather than their realisation. The bird's head is, unfortunately, lost to some extent in the distracting background, while its reflection in the water is aggressive in the extreme. Messrs. J. Bulbeck & Co. are represented by a large number of architectural photographs of a high order of merit; for No. 121 (*Norwich, North Choir Aisle*) they have received an award.

While on the subject of architecture, it is worth while remarking that the Exhibition this year is particularly strong in this direction. Messrs. Bulbeck & Co., Bolas & Co., Bedford Lemère, & Co., and Mr. H. W. Bennett all send work of a very high order of merit while Mr. Marriage's two "capitals" from Canterbury Cathedral (Nos. 329 and 335) compare favourably with his medalled work of last year. Mr. W. Thomas has scored a success this year with his *Ebb of a Winter's Day*, and we must congratulate him on having been there in time. Another two minutes and the day would have ebbed completely, but Mr. Thomas was there, and a figure is distinctly visible on the print. To our mind the *Corner of a Kentish Common* (No. 159), by the same exhibitor, is his finest production so far, and we are glad to see that he has gone in for work of more imposing dimensions. Hitherto many of his careful and delicate pictures have escaped examination by the public on account of their diminutive size; while we should be sorry to miss the charming hand-camera results which he exhibits, we are glad to see that he has adopted a course which will bring him under more general attention. The *Kentish Common* is one of the finest pictures in the Exhibition, the silver birches attract the eye at once, and the foreground, full of detail, but quiet and unobtrusive, leads one instinctively to the middle distance, in which the interest centers. The same exhibitor shows his versatility by *My Chum* (No. 158), in which a hairy terrier is well portrayed.

One medal this year goes to America, to Mr. Alfred Stieglitz, for *A Decorative Panel*. A tow path, on which is a group of goats, and puffing steamer tugging some barges up the steam, constitute the photograph which bears this name. In the sense that every beautiful framed photograph is essentially a decorative panel, the title is a good one, but its special applicability we are unable to detect. The atmospheric effect is well rendered, and the print is unexceptionable. In *Roses* (No. 245), by Dr. G. McDonald, which also takes a medal, we have as fine a photograph of the national flower as we have ever seen. The grouping is excellent, and the texture faithful to the extreme, but the print suffers from the frame, which is not suited to it, and distracts attention rather than concentrates it. The same remarks apply to No. 267, *The Potter*, by the same exhibitor, which narrowly misses being a highly successful result. Mr. C. F. Inston receives a medal for No. 291, *Waiting for the Wind*. In this a barge is seen silhouetted against a stormy sky, which suggests that the barge will not have to wait long; No. 284 is a very similar composition, and both possess a considerable degree of force, both are fine examples of the treatment of clouds. *A Modern Gallio* (No. 285), by Mr. Inston, represents a group of men on a street seat, and, as an example of natural grouping and of the artistic use of a hand camera, is as fine an example as the Exhibition contains.

Mr. Wilson Noble receives a medal for three X-ray photographs of the hand and forearm (No. 347), the heart and ribs (No. 348), and the foot (No. 349). Of these Nos. 347 and 348 are the most distinct of their size we have seen. No. 348 is good, but, being a much more difficult subject, is necessarily not so well defined.

Lantern slides have received one award, which goes to Mr. Paul Martin for a series of views of *London by Gas Light* (No. 360). They are exceedingly impressive on the screen, but, viewed in the hand, much of their charm is lost; the two enlargements of the same subjects on the walls (Nos. 101 and 119) hardly do them justice. Of the other exhibitors, some of the finest work is that by Mr. J. A. Sinclair, whose frames bear the inscription, "Not for competition." His *Dutch Peasant* (No. 8), an old woman crossing a market place, is of a kind with which he has made us familiar; while No. 16, *Sea, Sky, and Sand*, with its brilliant cloud effect repeating itself in a lower tone in the pools and wet sand, is the best of his work yet exhibited. One word to this exhibitor himself, and that is, that his prints suffer by being so frequently of exactly the same tone of carbon. Mr. E. Cecil Hertslet's *Wayside Shrine* is too regular in composition to be pleasing. *The Silent Mere* (No. 60), by the same exhibitor, is a soft, harmonious little picture, and much more satisfactory.

Colonel Gale, we must confess, disappoints us this year. Neat and pretty as ever, there is nothing about it that marks it out as being better than much of his former work, while more than one of his prints suffer by the heaviness with which the clouds are printed down. No. 229, *Mid-day Lunch*, is the most satisfactory, a group of horses in a ploughed field, the men, who are surely dining and not lunching, being seated at the hedgeside. The distant trees are suggested, while cumulus clouds betoken early spring. With Colonel Gale may fairly be bracketed Mr. B. Gay Wilkinson. The only criticism to be made on this gentleman's exhibits is, that they too closely resemble one another to be hung together as they are. Both Nos. 219 and 221 are striking groups of fishers round the boat in which they put to sea, and the black figures against the brighter sea and sky give a boldness and strength to the composition which is highly satisfactory. Mr. W. M. Warneuke is represented by a large portrait (No. 37) and by two landscapes. The portrait, which is the most imposing exhibit upon the walls, strongly suggests Whistler, and is a difficult subject cleverly treated; it narrowly misses being one of the finest photographs of the year. We say it narrowly misses being so, because there are one or two distracting elements which, once noticed, attract attention every time. A lady in a veil is seated, looking directly towards the spectator, on her right is a picture hanging on the wall, which is unhappily out of the horizontal, while the spots on the veil, one of which adorns the tip of the nose, while two others are symmetrically placed on the mouth, are aggressive. In other respects the portrait is a fine one, its dark tone and massive frame set it off to the best advantage. No. 63, *Evening*, by the same exhibitor, is successful as a picture, but unhappily it owes all its effect to a moon which is undoubtedly (complete with reflections to match), "made in Glasgow." *Our Village* (No. 100) is reminiscent of H. P. Robinson as far as the figure is concerned, and does not appeal to us as being up to Mr. Warneuke's usual standard.

We are glad to notice Mr. Alexander Keighley as an exhibitor once more. In No. 11, *An Alpine Cross*, a bold attempt is made in a figure subject, with the Matterhorn in the background. The idea is a good one, but the figures should be more prominent, or suppressed altogether. Mr. J. A. Hodges is another exhibitor whose work this year disappoints us, both here and at the Dudley Gallery, as also does Mr. T. M. Browrigg, whose prints suffer very greatly from the unsuitability of their frames. Under other circumstances, No. 137, *An Autumn Evening on the River Wey*, would be pleasant, but, in a brown frame, with a broad gilt matt, the delicate half-tones of the picture are quite lost.

Dr. Page May figures with no less than thirteen exhibits, of which some are relegated to the technical corner. The finest of these is a large and striking picture of the desert (No. 208), in which the vast waves of sand, with the varying play of light upon them, are seen stretched out beneath a cloud-filled sky. The sky and foreground are singularly harmonious, and an impressive result is obtained from most unpromising material. Some of his other frames are worthy of mention as excellent examples of what can be done with such hackneyed subjects as the pyramids and Sphinx, while a series of flashlight photographs taken in the desert, in the actual excavations themselves, of bas reliefs, &c., are of a high quality as regards technique, and of an interesting nature as far as their subjects are concerned, Queen Hatasu, the founder of the Egyptian navy, and her father Aahmes being sufficiently well depicted to show a marked family likeness.

Mr. G. Watmough Webster is represented this year by one portrait, *Mr. Gladstone in his Study* (No. 249), an excellent subject, well handled. The People's William is bending, in a characteristic attitude, over his table, littered with papers, and, doubtless, with postcards also, and, although little of his face is to be seen, the stooping figure and massive head are unmistakable at a glance. The Autotype Company send an enlargement from the well-known picture of Li Hung Chang and Mr. Gladstone, by Mr. Webster, which is hung in a conspicuous position, and will, no doubt, attract as much attention by reason of its subject as its execution, although both are worthy of praise. Mr. Tom Bright sends two pictures, *The Ever-busy River* (No. 19), and *In the Pool* (No. 21), of which the former is remarkably bright and sunny. Mr. Arthur E. Clementson's portraits (Nos. 33 and 39) are examples of good straightforward work, and are reminiscent of Valentine Blanchard at his best. No. 50, *Good Night*, by Walter Mawer, is a good subject badly treated, the lighting being as false as it could be; the candle is obviously impossible. This is strongly suggested in the little sketch in the catalogue, in which the artist has taken the liberty of showing how it should be done. A fine example of what can be done in the direction of the sacrifice of definition without offence is to be found in No. 43, *From Southern Climes*, by R. W. Craigie—the best work we have seen by this gentleman up to the present. The poses in the portraits by O. W. Huntington (No. 49) and R. H. Head (No. 51) are natural and unrestrained. Portraiture this year figures very strongly at Pall Mall, and is one of the features of the show. John Stuart sends portraits of *George Mason* (No. 200) and *E. J. Wall* (No. 215), the first-named being an excellent likeness of a well-known figure in the photographic world. Mr. Wall "wears a worried look"—the cares of journalism appear to sit heavily upon him; but, when we saw him on the occasion of the press view, he seemed better. The other examples by John Stuart (Nos. 31 and 47) are good, without calling for special remark.

Two groups of a vegetarian nature remind us that Mrs. Cadby is still to the fore, as indicating what may be done in the way of design by means of photography, but they bear no evidence of improvement on what has gone before by the same worker. Mr. W. A. Cadby sends us

the naked child in a fresh position (No. 210), (we are getting rather tired of that child, Mr. C.); he also exhibits No. 143, a distinct departure, in which a group of children are seen going down a slide. The picture is worth examination, the sense of motion and of instability is admirably conveyed by each figure, and the whole is most wintry in its suggestiveness. Mr. Pringle is at his best in a portrait of the late W. England (No. 146), another example of Artigue paper by the way. Mr. Mummery's two pictures (Nos. 150 and 166) are too similar to each other, and to some that he has exhibited before, to call for much comment, but as examples of carbon prints, on a paper the texture of which strongly suggests the painter's canvas, they are deserving of attention. Mr. Edgar G. Lee is disappointing, after his medalled picture last year; as also is Mr. Golding to some extent, who is represented by a single exhibit (No. 206). This is full of light and air, the clouds are suggestive of a slight breeze, and the river is well rendered, with its smoke and shipping in the distance, but all the same we have seen better work from his camera a year or two since; but the biliousness of his last year's work has fortunately passed off, so we have no complaint to make on that score. *La Haine* (No. 231), by Clarence B. Moore, conveys its meaning at a glance, but the expression after longer study is a little forced. It is, nevertheless, a powerful work, and he well shares with Stieglitz the burden of maintaining the reputation of American workers. Mr. G. Scamell sends a couple of pleasant landscapes at Chidingstone, and Messrs. Seymour Conway (No. 181) and Harry Tolley (No. 178) maintain their old won reputation with characteristic work.

Mr. J. H. Gear's exhibit is a remarkably fine one, and we are surprised that it has been passed over on this occasion by the Judges. *Silvery Morn* (No. 112) is the best we have seen of his, its only fault is a suspicion of uneven shading during printing in the distant trees. No. 205, *The Lowland Homestead*, by this exhibitor, is a charming evening landscape redolent of B. Gay Wilkinson. Mr. F. Hollyer sends a portrait of W. Watson in his usual style. We recognise in the book and the door, not to mention the table, Mr. Hollyer's simple and frequently used accessories. A fine work as regards technique is No. 274, a copy in platinum of *Prosperine*, by D. G. Rossetti, by the same exhibitor. Delicate and graceful, too, is *Winding the Skein* (No. 290), by Miss G. Stoddart. No. 293, by C. B. Keene—*Lath Kil Dale, Derbyshire*—is hardly up to last year's standard, and is a little spotty, but pleasant, nevertheless.

A most remarkable exhibit is that of Mr. Frank Haes, who sends three animal pictures—*Ruppell's Vulture* (No. 310), *An Ostrich* (No. 304), and *A Porcupine* (No. 303). These are each taken from half a stereoscopic wet-plate negative made in 1865, and will bear comparison with the finest modern work of the kind, in spite of the enhanced powers given to photographers by the dry plate. A careful study of this exhibit is most instructive. Henry Noth's plant pictures are good examples of a branch of applied photography of which more use might be made than is the case, and Fred Marsh's flashlight interiors are remarkable. No. 337 represents an underground kitchen in a "doss house," and was taken at 11.45 p.m. It seems to give a good idea of such a domicile, but we are unable to vouch as to its fidelity from actual experience. Mrs. C. W. Ward exhibits a good reproduction of the Davenant bust of Shakespeare (No. 341); while Mr. Lodge sends pictures of birds and nests, which could only have been obtained under great difficulties.

Captain Tottenham exhibits a couple of photographs taken during the Chitral campaign, and Mr. T. A. G. Strickland four views of a beetle from the Transvaal, known by the cheerful title of *Brachycerus apterus*. (No. 316).

The lantern slides call for little remark, and the stereoscope contains but two exhibits, by Mr. Fortescue Mann, and Mr. F. Dunsterville, respectively.

Apparatus is limited to the Incanto acetylene gas generator, and the Incanto lantern fitting by Thorn & Hoddle, the Memorandum and 5 × 4 Frena cameras by R. & J. Beck, Limited., the Scientific hand camera, Sanderson's camera and some printing frames by Houghton & Son, the brilliant view-finder and "Censabul" focussing chamber by Adama & Co., the Stigmatic lens, J. H. Dallmeyer, Limited, a large process camera and an instantaneous lens flange by W. Watson & Sons, the Xit and other cameras by J. F. Shew & Co., a lantern carrier and an arrangement for making photographic doubles. Most of these we have at one time or another described in our columns, and we cannot now do more than mention them.

In addition to those exhibits to which we have referred, there are on the walls at Pall Mall many others well worth the visitor's attention. As we said before, the Exhibition, as a whole, is of a very high quality, certainly the best both as regards quality and arrangement that the Society has ever held. We are glad to note that the Royal Photographic Society has not accepted the impertinent suggestions made to it from time to time to relinquish the care of the art side of photography to the self-appointed critics of the Linked Ring; and that, on the contrary, in spite of a spirited opposition, its forty-first Exhibition is its best within recollection. While the work is good in quality, much care has been given to its adequate display, even to such a comparatively trifling detail as the toning down of the number labels to a tint harmonising with the particular frame each is upon. The Exhibition improves on acquaintance, and we left it after our last visit with a higher opinion of its merits than at the commencement. No photographer who can by any means manage to visit it should omit to do so. To the charms of the pictures themselves are added demonstrations of X-ray photography every day at 3.30 p.m., and of the Birt Acres Kinematoscope every Monday, Wednesday, and Saturday evening at 8.45.

THE PHOTOGRAPHIC SALON.

(Second Notice.)

A second visit to the Exhibition at the Dudley Gallery gives us the opportunity of supplementing our last week's notes. We then made allusion to some examples of the bichromated gum process, which did not appeal to us as very satisfactory examples of photographic printing. Dr. Henneberg selects this method of printing for several of his exhibits, notably *Stormy Weather* (No. 9), in which the effect of wind is well conveyed in the swaying trees. There are two tones in the picture, black and blue-black, and the process suits the particular subject. But, with other examples, Dr. Henneberg, as well as Messrs. Watzek and Kuhn, who also send bichromated gum pictures, gets patchy effects, which we do not think likely to achieve any other success than that of curiosity. The head of the *Tyrolese Hunter* (No. 12), by A. Kuhn, in red pigment, is extremely good, being free and unconstrained in posing. M. Colard's idea of *A Fine Day in London* (No. 14) is not ours. It conveys to us the impression of fog and mist. But then we live in London and M. Colard does not, so that there is plenty of room for difference of opinion on the subject. Major J. Fortune Nott's excellent representation of a *Caravan in the Desert* (No. 24) would, in our opinion, have been improved by the elimination of some of the foreground. *Better be Merry than Wise* (No. 27) is the happily chosen title for a study of two laughing young women. It is so well done that we shall expect to see further work from Mr. McNay, who is a new exhibitor to us.

Some of the foreign exhibitors impress us by their powerful work, others puzzle us. Commonplaceness is what we think characterises the group of *Fishing Boats* (No. 29), by Paul Bourgeois, for it is pretty without being pictorial. Again, *Old Women* (No. 33), by Ach. Darnis, is just an ordinary group of three old dames that should have no place here, where everything is supposed to be so very pictorial. *A Portrait* (No. 36) of a lady, by Mr. W. Howard Hazell, is a small but pleasing and able representation of a lady about, we should think, to depart for the opera, the theatre, or a dinner party. *A Child's Head* (No. 37), by Mr. Eugene Lee Ferguson, is capital, but unnecessarily soft, even to mistiness, and giving us the idea that the effect aimed at has been over-accentuated. Other exhibitors besides Mr. Ferguson impress us in a similar manner. A lurid and bloodthirsty person is portrayed by Mr. F. W. Gauntlett in *The Anarchist* (No. 46). It is a clever contrast of light and shadow, and a highly effective portrait study, but Mr. Gauntlett should not use his cleverness for the purpose of tickling the groundlings. Anarchists are not necessarily fierce and wicked-looking. We have seen a great many that are bland and respectable-looking persons, who might, as far as appearances go, be prosperous pork butchers and members of vestries.

We note several portraits by Mr. Hay Cameron which call for no comment but that which we have so many times before bestowed on Mr. Cameron's work; they are mostly uniformly good and natural. Good, too, is the portrait of *Mrs. Bruce* (No. 54), by Mr. J. C. L. Knight Bruce. We seem to be looking at the portrait of a lady in her habit as she lives—a happy and spontaneous production, not the elaborated and excessively careful outcome of a studio *séance*. Mr. Knight Bruce has, as it is customary to say, scored. Mr. Thomas Manly's *Gloriana* (No. 55) is a frightened-looking young person with towzled hair, surrounded by a halo, and the photograph has a bilious-yellow tone. If allegory be the underlying idea of this production, we must own that, in this case, we fail to follow Mr. Manly. What fine scope it offers to the caricaturist, as does Mr. Cameron's *My Uncle John* (No. 63), the original of which would appear to be very startled at the operation of having his photograph taken. The high lights in Mr. James Brown's otherwise effective view, *A Windy Morning* (No. 61), has been apparently produced by a

lavish display of Chinese white. We cordially congratulate Mr. Ralph Robinson on his *Solomon J. Solomon* (No. 70). The popular painter is standing before his easel, and a perfect bit of artist-at-home portraiture is the result. It is really so photographically good that we are surprised the Committee of the Salon did not reject it.

This Exhibition will long remain a surprise to us by reason of the difficulty we experienced in realising or discovering the effects alleged to be present in some of the results shown. Thus, that able worker, Mr. Leslie Selby, is one of the first to baffle us. He calls a charming little view *Evening by the Sea* (No. 64), but, however intently we regard the photograph, we do not realise that it depicts the approach of night. Mr. L. C. Richards is to us equally ambiguous. His *Jolly old Friar* (No. 75), which we have seen before, looks to us like the head of a smiling old *woman* in monk's garb. It is not *mannish* enough. The rubicundity, the rotundity, and general coarseness of the jolly old friar of conventionality are, in our eyes, absent. The pretty and well-favoured young lady, too, in Mr. Burchett's *Poverty* (No. 82) does not bear out the title; and Mr. F. Coop, in *Above the Morning Mists* (No. 83), which is a photograph of a quaint little village, has utilised his abilities to produce a pretty but pointless effect. What is "above" the morning mists? The view? If so, therefore what, Mr. Coop?

Rev. F. C. Lambert is represented by three frames, in one of which is a delightful study of a dear old lady, *Granny* (No. 95). The arrested attitude of the old dame and the shrewd and kindly expression of her aged face have been cleverly taken advantage of to produce an excellent result. *Ruth* (No. 91) is the title of a pleasing study of a young girl, by Mr. Sutcliffe. The effect is that of ease and gracefulness. Mr. Alfred Werner strikes the key of drama in *Evicted* (No. 93), depicting a woman on the country side looking back towards the humble home she is leaving. In *Autumn Morning* (No. 97), Mr. Paul Naudot contrives to impart to his view, with its leafless trees and advancing figures, quite a chilly atmosphere. It is, besides, a crisp, clear, vigorous photograph, decisive in style, and therefore all the more welcome amidst much that is produced to prove how very unlike anything resembling a photograph it is possible to make a photograph.

There is so little humour on the walls of the Dudley Gallery that Mr. J. W. Eadie's *Playmates* (No. 120), two kittens at play, a clever and pretty little photograph, comes as a welcome relief. We have already made reference to Mr. Lionel C. Bennett's absorbing view of a telegraph pole, its proper title being, we observe from the catalogue, *On the Banks* (No. 122). His other works are less eccentric than this, for which he, nevertheless, asks the extraordinary price of 3*l.* (guineas would have *looked* better, Mr. Bennett); but, in our humble opinion, they do not show Mr. Bennett at his best. *An Essex Quay* (No. 123) is perhaps the ablest of the four, although it is difficult for us to decide whether the vessels at the quay side are lying on mud or in water. Last week we overlooked one or two of Mr. E. R. Ashton's Egyptian landscapes, otherwise we should not have charged him with the sin of monotony. His *Egyptian Pastoral* (No. 132) and *Evening near the Pyramids* (No. 133) are both beautiful views, which stamp him as being very versatile in camera work. Mr. R. W. Robinson also sends some very fine landscapes and seascapes, which some few years ago would have been hailed as revelations, now they are accepted as a matter of course. Mr. Robinson, however, well holds his own in portraiture, his *Sir John Everett Millais* (No. 171) meeting with general applause, to which its simplicity and dignity entitle it. In *October Morning* (No. 160) M. Desiré De Clercq has a novel and, we think, hardly natural effect; the light streams down like so many sheets of vapour. The effect is certainly overdone. There is a little hardness in Mr. Burchett's charming study of a flower-decked lady, *Ceres* (No. 198), otherwise it is entirely successful. *Rosebud* (No. 143) is the title given by Mr. H. Irving to an exquisitely modelled, half-draped bit of "statuary;" and some admirable figure studies come from Mr. A. B. Langfield. Mr. E. Atkinson makes the most of an old subject, *The Weed Burner* (No. 162); and, of the many contributions of Mr. Karl Greger, *Gower Shore* (No. 164), with its wonderfully realistic effect of seashore sands, is probably his best. *Cornfields* (No. 176), by Mr. C. Moss, is surely wrong in tone and too heavy and dark for such a subject. *The Potter* (No. 182), by De Clercq, an interior study of a potter at work, is somewhat halated, otherwise it is good *sui generis*. Some admirable portraits by Mr. Van der Weyde—his *Lord Leighton* (No. 215) deserves particular notice; Harold Baker, Hollyer—his *W. E. Henley* (No. 241) is decidedly his best—W. Crooke, and Alfred Geruzet, will, doubtless, attract the visitor's attention. Indeed, in this respect the Salon exhibitions are always particularly worthy of patronage. They are helping slowly but surely to kill the "commercial" portrait of former years—the over-retouched, artificially posed, simpering, wooden, characterless, and manufactured article that has too long passed current as photographic "portraiture."

One of the best things shown is Mr. N. S. Kay's *A Critic* (293). The critic is Trilby, and she is seated, intently scrutinising a picture that she is holding. Alike in skilful arrangement and naturalness of rendering, this photograph appeals to the eye as a sound and satisfying piece of work.

We have mentioned, we think, the salient features of this fine Exhibition, and bare reference to the names of D. W. Wynfield, A. J. Golding, C. J. Berg, J. Bushby, Hall Edwards, Stieglitz, Bremard, G. H. James, J. Bulbeck, W. A. Cadby, H. E. Davis, Frances B. Johnston, Janet Reid, A. Barbichon, Mrs. Hodgson, and F. H. Evans must suffice as a general indication of the other exhibitors whose works most took our fancy. But as we said last week, we consider the work of La Begue, Paul Bergon, C. Puyo, Horsley Hinton, and Craig Annan to be the best shown. It is photographically as well as pictorially good, and therefore appropriates a double claim to our regard.

The Exhibition remains open till November 7, and well deserves to be visited.

PHOTOGRAPHIC CHEMICALS AND THEIR ADULTERATIONS.

II.—Sodium Salts.

Acetate of Soda. — The commercial acetate may contain sulphate of soda, sodium chloride, lime, and traces of calcium sulphate. Seeing that the salt is extremely deliquescent, the percentage of absorbed moisture should, first of all, be determined by drying a weighed portion of the sample in a water bath, and noting the loss of weight. The dried salt is then to be dissolved in as small a volume of water as possible. Should any white residue—consisting of calcium sulphate and a little lime—remain behind, it may be separated by filtration, dried, and weighed. The concentrated solution should then be largely diluted with water, and divided into three equal portions. In the first portion the sulphuric acid is to be determined by precipitation with barium chloride in the usual way. The percentage of anhydrous sulphate of soda is then calculated from the weight of the barium sulphate obtained, 233 grains of the latter being equivalent to 142·4 of the former. In the second portion of the solution chlorine is estimated volumetrically by means of a standard solution of nitrate of silver, similar to that employed in the analysis of potassium bromide. The operation is to be carried out in the manner already described, chromate of potash being employed as an indicator. A hundred measures of the standard solution are equivalent to ·292 grain of sodium chloride. In the third portion of the aqueous solution the dissolved lime must be precipitated, by the addition of ammonia and ammonium oxalate. The precipitate of oxalate is boiled, filtered off, well washed with hot water, dried, and finally strongly incinerated in a porcelain crucible, whereby it is converted into carbonate of lime. Ten grains of the carbonate are equivalent to 5·6 grains of lime. The weight should be added to that of the insoluble lime and calcium sulphate.

Biborate of Soda.—The commercial salt, better known by the name of borax, frequently contains, as impurities, sodium chloride, sulphate of soda or ammonia, and traces of aluminium sulphate, the last-mentioned salt being usually present in the form of an alum. To detect sodium chloride, dissolve a portion of the sample in water, and add in excess a weak solution of nitrate of silver. The precipitate will consist of a mixture of borate, sulphate, and chloride of silver. On treating it with dilute sulphuric acid, added in excess, the borate and sulphate of silver will be completely dissolved, but the chloride, being insoluble in that acid, will remain behind. Should the precipitate dissolve entirely, it is a proof that the sample is free from chloride. The sulphates may be detected by treating the borax aqueous solution with barium chloride. Again, a mixed precipitate will result, this time of the borate and sulphate of barium. Treated with dilute nitric acid, the former will dissolve, leaving the latter as a residue. In this case, after boiling the liquid, the precipitate may be collected on a filter, washed with hot water, dried, ignited in a porcelain crucible, and weighed. The percentage of sulphate or sulphates in the sample may then be calculated. Every 23·3 grains of the precipitate are equivalent to 8 grains of sulphuric anhydride, or to 14·2 grains of anhydrous sodium sulphate. If any alum be present unprecipitated in the solution of the sample, it may be precipitated, in the form of alumina, by the addition of a strong solution of ammonia. The precipitate should be collected on a filter, washed, dried, ignited, and weighed. Every 10·28 grains of the dried precipitate are equivalent to 90·68 grains of crystallised ammonium alum. When alum is present in quantity, a white precipitate is invariably formed when the sample is dissolved in water. This is the borate of alumina, a salt of uncertain composition. It usually contains about 38 per cent. of alumina.

Bicarbonate of Soda.—This salt is seldom so seriously contaminated as to be unfit for use in photographic processes. Samples sometimes contain some neutral carbonate, moisture, and traces of sodium chloride and sulphate. For the detection and estimation of these the reader may

refer to my remarks on the bicarbonate of potash. The solution of oxalic acid, there described, will be found useful for estimating the percentage of pure bicarbonate present in the sample. The volumetric operations with this solution are to be carried out in precisely the same way as in the case of the potassium salt; only, in making the calculation, it must be borne in mind that 1000 grain measures are the equivalent of 8·4 grains of pure bicarbonate of soda.

Carbonate of Soda.—The ordinary carbonate, or "washing soda," is one of the crudest salts in the market. Moreover, as regards its water of constitution, it is a salt of a very variable composition. For photographic purposes the anhydrous carbonate, when it can be procured, is much to be preferred; and, as it may at all times be easily produced by heating the pure bicarbonate to redness, it is surprising that the crude hydrated salt should be so largely employed for developing and other purposes. The complete analysis of the commercial salt is too lengthy and complicated a process to be described in detail. The chief impurities likely to be met with are the following:—Free alkali, sodium chloride, sulphate of soda, sodium sulphide, sulphite of soda, and thiosulphate of soda. The salt last mentioned is, I need hardly say, an impurity of the harmful class, and one of whose absence the photographer must be careful to assure himself when selecting a sample for use. It may be detected by treating the aqueous solution of the carbonate with excess of moderately dilute hydrochloric acid, and boiling in a flask over an Argand burner. If thiosulphate be present, the solution will become turbid from the deposition of sulphur, and sulphurous oxide gas will be given off, and may be recognised by its odour of burning sulphur.

If, however, the odour is that of sulphuretted hydrogen, the presence of sodium sulphide is to be inferred, and may be confirmed by the blackening of an acetate of lead test paper held in the stream of the evolved gas. Lastly, if sulphurous oxide be given off without deposition of sulphur in the liquid, sulphite of soda is present. As a confirmatory test for the latter a scrap of zinc may be added, and, on again heating, sulphuretted hydrogen will be evolved.

Sodium Chloride.—Common salt is often contaminated with magnesium chloride. The presence thereof may be inferred should the sample show signs of deliquescence on prolonged exposure to air. The percentage of the adulteration may be estimated by treating the aqueous solution of the salt with ammonium chloride, ammonia in excess, and solution of phosphate of soda. After stirring the liquid and allowing it to stand for several hours, the precipitate must be collected on a filter, washed with dilute ammonia, dried, ignited, and weighed. The ignited product is pyro phosphate of magnesia, each ten grains of which are equivalent to 8·56 grains of magnesium chloride. Should the sample contain (as it probably will) some silicous or ferruginous matter insoluble in water, this must be separated by filtration, and dried and weighed before precipitating the phosphate. Moisture may be determined in the usual way by heating a weighed portion of the sample in an oven or water bath.

Phosphate of Soda.—The crude phosphate contains sulphate of soda, and occasionally traces of carbonate of soda and phosphate of lime. The sulphate of soda may be estimated by precipitating with barium chloride, and boiling with dilute hydrochloric acid, in order to dissolve the precipitated barium carbonate and any phosphate of lime that may be present, after which the residual sulphate of barium must be filtered off. Phosphate of lime may be detected by its insolubility in water, and carbonate of soda by the effervescence which ensues when the powdered sample is treated with hydrochloric acid.

Sulphite of Soda.—The neutral sulphite of commerce is sometimes contaminated with carbonate and sulphate of soda. The latter is from the photographer's point of view a somewhat objectionable impurity. It may be detected and its amount estimated in exactly the same manner as when present in a sample of phosphate of soda. Another very objectionable impurity of which traces may be found is thiosulphate of soda. This salt is often formed when imperfectly washed sulphurous oxide has been employed in the manufacture of the neutral sulphite. It may be detected by the deposit of sulphur produced on heating the aqueous solution of the sample with dilute hydrochloric acid, and also by the gradual change in colour from white to brownish-black of the precipitate which is produced when nitrate of silver is added.

Thiosulphate of Soda.—The impurities of the commercial salt vary according to the mode of manufacture. It may contain free alkali (soda), sodium sulphide, carbonate, sulphite, and sulphate of soda, besides minute traces of chlorides and earthy oxides. Of these the sulphide of sodium perhaps deserves a place in the class of objectionable or active impurities. Samples containing free alkali should be regarded with suspicion, for in these this impurity is most likely to be found.

The following scheme of analysis may be adopted:—

1. Dissolve fifty grains of the sample in water, and precipitate the thiosulphate and other soluble salts by means of a strong solution of nitrate of lead. Filter off the precipitate, wash with warm water, and add the washings to the filtrate along with enough potassium sulphate solution to precipitate any free lead nitrate. Filter and wash any precipitate formed, add the washings to the filtrate as before, and then titrate the latter with the standard oxalic-acid solution, using litmus as an indicator. One hundred measures of the solution are equivalent to ·31 grain of anhydrous soda. Calculate the amount of alkali present from the number of measures consumed, and multiply the result by 2. The product is the percentage of free alkali in the sample.

2. Dissolve 100 grains of the sample in water, and divide the solution into three equal portions. To each of these add strontium nitrate solution in excess, stir, and allow the precipitates to stand for five or six hours. Call these precipitates A, B, and C.

When the precipitation is complete, collect precipitate A on a dried and weighed filter, and after washing dry it in a water bath. Weigh the dried precipitate and filter, and deduct the weight of the latter. To the filtrate and washings from A add solution of chloride of zinc in slight excess. Stir, and allow the precipitate of hydrated zinc sulphide to subside. If no precipitate is formed, the sample is free from sodium sulphide. Collect any precipitate on a weighed filter, wash, and dry at such a heat as will suffice to expel the molecule of water in combination with the sulphide. Weigh precipitate and filter, and, after deducting the weight of the latter, multiply the remainder by 780, and divide the product by 972. The quotient multiplied by 3 will give the percentage of anhydrous sodium sulphide in the sample.

3. To the vessel containing precipitate B add dilute acetic acid in slight excess, and, to that containing precipitate C, dilute hydrochloric acid.

If, on stirring, both precipitates dissolve, precipitate A consists wholly of strontium carbonate, and therefore the sample contains carbonate of soda, but no sulphate or sulphite. Should precipitate C alone entirely dissolve, the sample may contain carbonate and sulphite, or only the latter. Collect the precipitates on weighed filters, wash, dry in a water bath, weigh, and deduct the weight of the filter in each case. If the weight of A is exactly equal to the weight of B, and that of B in its turn to the weight of C, the precipitate in each case consists wholly of strontium sulphate. If only A and B are equal in weight, each consists of a mixture of strontium sulphate and sulphite, and C of sulphate alone. If A exceeds B, deduct the weight of the latter; the remainder is the weight of the carbonate of strontia in the mixed precipitate.

Deduct C from B. The remainder is the weight of the sulphite in the mixed precipitate, and C itself is the weight of the sulphate. When B and C are equal in weight, no sulphite is present in the sample.

When the weights of A and B are the same, and there is no precipitate C (it having dissolved entirely in hydrochloric acid), each consists wholly of sulphite of strontia.

When, under the same conditions, A exceeds B, deduct the weight of the latter, and the remainder will be the weight of the carbonate, and the weight of B itself that of the sulphite.

4. Multiply the weight of the carbonate precipitate by 1060, and, after dividing the product by 1475, multiply the quotient by 3. The product is the percentage of anhydrous carbonate of soda in the sample.

Multiply the weight of the sulphite precipitate by 1260, and, after dividing the product by 1675, multiply the quotient by 3. The product is the percentage of anhydrous sulphite of soda in the sample.

Multiply the weight of the sulphate precipitate by 1420, and, after dividing the product by 1835, multiply the quotient by 3. The product is the percentage of anhydrous sulphate of soda in the sample.

III.—Ammonium Salts.

Ammonium Chloride.—The commercial chloride nearly always contains ferric chloride and traces of sulphate of ammonia. The former is an impurity of the harmful class. Its presence in a sample may be detected by treating the aqueous solution with ammonium sulphide, when the iron will be precipitated as sulphide of iron. One hundred and seventy-six grains of the dried sulphide are equal to 325 grains of anhydrous ferric chloride. The sample may be purified for photographic purposes by treating its concentrated solution with ammonium sulphide, filtering off the precipitated iron salt, and adding dilute hydrochloric acid to the filtrate. The solution is then heated to expel the hydrogen sulphide, the excess of acid is neutralised with ammonia, and the salt is recrystallised by evaporation. To detect sulphate of ammonia, test the sample with barium chloride solution in the usual way.

Ammonium Bromide. — This salt is one of the few which are to be purchased in a fairly pure state. Occasionally, however, traces of carbonate of ammonia may be detected in low-priced samples. For analytical purposes the percentage of bromide should be estimated volumetrically in the manner prescribed for the bromide of potassium. A hundred grain measures of the standard solution of nitrate of silver are equivalent to ·49 grain of ammonium bromide. Not less than fifty grains of the dried sample should be taken for analysis.

Carbonate of Ammonia.—The commercial salt is an impure sesquicarbonate prepared by dry distillation. It generally contains several of the salts of the ammonia series, among the most common of which may be mentioned the bicarbonate, carbamate, chloride, and sulphate. It may also contain a little oxide of iron. The bicarbonate is insoluble in alcohol. The sesquicarbonate is decomposed by the same solvent, yielding two molecules of insoluble bicarbonate, and one molecule of soluble normal carbonate. The carbonate is converted into normal carbonate when dissolved in water.

These peculiar reactions interfere with the analytical processes for the determination of these impurities, and therefore the true composition of the sample can seldom be exactly ascertained, except by a very skilled chemist. Ammonium chloride may be detected by acidifying the aqueous solution with nitric acid, and adding nitrate of silver, when, if any chloride be present, it will be precipitated. In another portion of the

strongly acidified solution the addition of barium chloride will produce a precipitate if sulphate of ammonia be present. Oxide of iron may be detected by treating the solution with ammonium sulphide, whereby any iron salts will be thrown down in the form of a black powder.

Ammonio-aluminium Sulphate.—The common ammonium alum nearly always contains chlorides. Of these the two chlorides of iron must be ranked as objectionable impurities, and ammonium chloride as a contamination of the harmless class.

To detect the former, add to the boiling aqueous solution of the sample enough solution of caustic potash to dissolve the white precipitate of hydrate which is at first formed. A reddish-brown residue will indicate the presence of iron. If, however, the sample should contain a considerable percentage of ammonium chloride, a double salt will be formed, and the iron will not be precipitated. Therefore, as a confirmatory test, the aqueous solution should be boiled with a little dilute nitric acid, and tested with ferrocyanide of potassium, when, if iron salts be present, a blue precipitate will be formed. The presence of ammonium chloride in the sample may be disregarded, as it does not disqualify it for use in those photographic processes in which the alum is likely to be required.

Ammonium Sulphocyanide. — The composition of the commercial sulphocyanide varies according to the manner in which the salt has been prepared. It sometimes contains a little free sulphur and a small percentage of carbonate of ammonia. The sample may be purified from the former by filtering the aqueous solution and evaporating the filtrate to dryness. To detect the latter, add to a small portion of the filtrate calcium-chloride solution, when any carbonate present will be at once precipitated as carbonate of lime. MATTHEW WILSON.

LOWTHIME'S DEVICE FOR FACILITATING THE INSERTION OF PHOTOGRAPHS IN ALBUMS.

MR. LOWTHIME'S invention relates to an instrument for facilitating the insertion of photographs and the like—particularly those unmounted—in albums, the object being to overcome the difficulty of getting the bottom edge of the photograph or the like to enter the groove at the bottom of the opening.

The patentee says: "According to this invention I take a plate of metal, celluloid, cardboard, or other suitable material, of a width approximate to the width of the photograph to be inserted, and of such a length that, when it is inserted in the recess in the leaf of the album, it stands clear of the top thereof so that it can be conveniently withdrawn. In this plate is cut, firstly, a vertical slot preferably at or about the centre of the plate, and, secondly, two or more small holes adapted to show one or more of the edges of the opening in the leaf when the plate is in position in the recess therein.

"In use this plate is first passed into the recess in the leaf of the album and the photograph is then passed in behind the said plate, which acts as a guide for it past the bottom edge of the opening, and allows it to be easily drawn into position by the finger through the vertical slot in the plate, the other holes therein allowing the manipulator to see that the edges of the photograph are covered by the edges of the opening before withdrawing the plate.

"As a modification the plate may be made with two or more strips on the back, so that the photograph can first be inserted on the back of the plate, and then inserted into the recess in the leaf of the album through the medium of the plate."

"FOREWORDS" TO THE SALON CATALOGUE.

As usual, we take occasion to reprint the "forewords," or introduction, to the catalogue of the Photographic Salon Exhibition. They are based on wholly erroneous assumptions that, prior to the establishment of the Salon, "pictorial work in photography" was unrecognised by then existing Societies, and that now the Salon is the only "place of its own" that pictorial photography possesses. All but a handful of members of the Linked Ring will be highly amused by the blitheness of these "Forewords."

"There has been much talk in recent years concerning the position among the arts which pictorial photography is entitled to occupy.

"The establishment of the Photographic Salon, showing the truer method of using photography as a means of graphic expression, was the signal for persistent attacks upon its supposed pretensions.

"These pretensions were in the minds of those only who built them up. Their method consisted in assailing positions which had never been occupied by the men whose aims they sought to vilify.

"The object of the Photographic Salon is to give to pictorial work in photography a place of its own, and to set a standard of value by which it should be estimated, without reference, of necessity, to the conventions and principles established by other graphic methods.

"The Salon claims for this work a position of independence, and is no longer satisfied that pictorial photography should be called the handmaid of the arts; still less that it should be a hanger-on to the skirts of abstruse science in optics, chemistry, and mathematics.

"The examples here exhibited are submitted to the intelligence of the public, with full confidence in its recognition that the pictorial application of photography need not, as it did for so long a time in its previous career, degrade truth to the level of fact, or be incapable of the power of suggestion and of the intellectual expression of nature, instead of the bare registration of the obviously existent."

The Inquirer.

*** *In this column we from time to time print questions that may be addressed to individual contributors to our pages, or such as are sent to us with the view of eliciting information from a variety of sources. We invite the co-operation of our readers in rendering this feature of the* JOURNAL *useful and instructive.*

ARON'S ELECTRIC LAMP (To S. J. M.).—The Editor of *Apollo* writes: Aron's Electric Lamp may be purchased from the manufacturers, D. R. Muencke, Lusenstrasse 28, Berlin, N.W.

RETOUCHING SURFACE.—JAPHET writes: "I have tried 'Country Professional's' method, as given in last week, but can't get quite enough lead on to the film. Is he sure he has not given a formula for polishing the surface?"

DEFECTIVE PNEUMATIC HOLDER.—GELATINE writes: "Seeing a query about a pneumatic holder in this week's JOURNAL, may I ask advice about mine. It is nearly new and apparently perfect, but it will not hold a plate for more than a few seconds at a time. I have tried all means, wetting the disc, &c., and can find no leak in the bulb, or anywhere. Can you tell me where the fault is?"—See reply to "Collodion" in this column. The leak is no doubt in the metal tube, by which the ball is connected with the frame.

PERISHED INDIARUBBER.—B. W. says, in reply to "Collodion:" "I have a pneumatic holder that has been in my possession at least twenty years, and which was in exactly the same condition as the one described. I disconnected the ball and its tube from the wooden handle, and placed them in warm water—not hot—and in a few hours the ball regained its elasticity. A new disc was obtained from a dealer—cost, about 1s.—and when the thing was put together again it was, and is, equal to new. I was slightly troubled at first by its "losing wind" in use, but, on unscrewing the screw and touching the point with indiarubber paste before putting it together again, the leakage was entirely stopped, and it will now remain attached to a plate for hours.

SPOTTING PRINTS AND NEGATIVES.—SPOTTER writes: "In reply to 'Beaten,' spotting requires both skill and proper materials. In the first place, it is no use trying to work with inferior brushes. The finest and best sables only will answer, such as are capable of taking a perfect point. Then, the colour must be mixed with some suitable adhesive, and for this purpose sticking the brush in the mouth is about the best way of courting failure. With good water colour pure water suffices, but I always prefer to use a little thin starch, or to rub the colour up with starch paste. This will make it adhere nicely. For prints only ordinary skill is required, but spotting out pinholes in negatives is more difficult. I find liquid colour, applied with a crow-quill pen, as convenient as anything."

PURE WATER (To W. Finlay).—The following helped me out of a similar difficulty to yours, and may probably prove as useful to you. I procured, first of all, a large earthenware jar, used, I think, for pickling purposes, something the shape of the oil jars used in "Ali Baba" pantomimes, and holding about five or six gallons. This cost about two shillings, and is fitted with a lid, having a hole in the centre for lifting off. Then I got a large flower-pot, about a foot in diameter at top; this fits comfortably into the larger jar, the lid of which, in turn, fits into the flower-pot, about half way down. Into the hole in the flower-pot a small piece of sponge is plugged; then a layer of well-washed silver sand is placed; over this, a layer of granulated, not powdered, charcoal; and over this, again, more sand until the level of the lid is reached. The latter serves to prevent the sand washing up when water is poured in. The charcoal costs about sixpence per pound, and one pound serves as a charge for the above size, and lasts for a long time—some months. When filtration becomes slow, scoop out the upper surface sand without disturbing the charcoal; wash it well and return it. This will keep me supplied with clean water all day long, but it has to be "dipped" out of the lower jar, which is rather awkward, especially when the flower-pot is pretty full, and consequently heavy. If I were making another, I should get a good wooden barrel and tap.—W. C. HOLMES.

CHROMATE OF POTASH.—There is no great difficulty in the preparation of neutral chromate of potash from the bichromate, but probably J. H. F.'s failure arises from his method. Theoretically, if 8 parts by weight of potassium hydrate be added to 21 parts of the bichromate, the resulting solution will consist of the "neutral" salt, but practically it is better to work with a slight excess of alkali if the product is to be collected in crystals. In this case the proportions of 8 to 20 may be used. Perhaps J. H. F.'s difficulty comes in trying to produce the crystals, as, when the solution is evaporated, there is a strong tendency towards the formation of crystals of the bichromate, and spontaneous evaporation is the only reliable method. Owing to the great difference in solubility of the two salts, if the bichromate be first dissolved, the resulting solution will be so far removed from the point of saturation of the neutral salt that the spontaneous crystallisation will prove a very tedious job. Let the following plan, therefore, be adopted: Dissolve 8 parts of caustic potash in 60 parts of water, and add gradually 20 parts of bichromate in powder. Shake well until dissolved. Although the bichromate would not itself dissolve in the above quantity of water, as it becomes reduced to the neutral condition, its solubility is greatly increased, and, by the time the conversion is complete, it will be found to all go into solution, especially if the vessel be warmed. Then set aside to crystallise.—SYNTAX.

RETOUCHING MEDIUM. — As "Portraitist" does not seem to have received exactly the information he requires, I offer these few hints in the hope that they may be useful to him and others similarly situated. In the first place, he must observe that a retouching medium, to give a uniform surface, must be studied, and all the small points leading to success and failure noted. The very fact that sometimes he obtains a reliable surface proves that the medium is all right, and that, given uniform conditions, success must be assured. After an extended trial of all mediums in the market during the last ten years, I have no hesitation in saying that the very medium against which "Portraitist" is rather severe (I think I have the same as him in my mind) is the very best for retouching *on the film;* but it undoubtedly requires mixing with a greater quantity of *brains* than does an ordinary resin in turps mixture. Let "Portraitist" try this method of application. Make the negative as warm as for varnishing; then, having placed the finger in a piece of soft rag, apply a small quantity of medium by means of cork to rag, and rub over negative in usual manner. This part of the business is the most critical; he must not rub on too much medium or too little, or put it on too thick or too thin, but just the right amount to suit his touch, and this can only be found by trial. Now heat the negative again, and when it cools he should have a surface of the very best; if found not dry enough, heat negative again. If negative is not required to be worked till next day, the first warming will be found sufficient. Use a Hardmuth's "Koh-i-Noor" H pencil for all ordinary and HB for any extra heavy work; *no other pencils* work like these with this medium. Be most careful to keep the cork of the bottle free from "stale" medium, which will accumulate on the sides and the mouth of bottle, and which is so gummy and sticky that if once on the negative it will never dry. Never use the same place in rag twice. The great advantage of this medium, and which places it above all others, is that, with careful varnishing, *it will keep all the work put on,* and only a retoucher can realise what this means. Heat negative slightly when varnishing, and dry up quickly. These remarks apply *only to touching on the film,* for, if applied to the varnished surface, this medium, in my hands, is only a delusion and a snare; and for this latter purpose no better medium can be obtained than that which Mr. Harold Baker offers to send to "Portraitist."—J. E. GOWER.

Our Editorial Table.

CONVENTION REMINISCENCES.

By J. A. Kay, 211, Lord-street, Southport.

MR. KAY modestly terms the photographs he has sent us "a few Reminders of the Convention week." The reminders, however, fill a dainty and artistic little album, and number in all twenty-four. They include views of Fountains Abbey, Ripon Cathedral, York, Studley Royal, Bolton Hall and Woods, Knaresboro', landscape as well as architectural subjects having been chosen. Mr. Kay's work evinces a very high degree of artistic and technical skill, and we shall prize his photographs, not merely as Convention reminders, but for their own intrinsic good qualities.

THE ACME PRINT TRIMMER.

H. J. Redfern, 55, Surrey-street, Sheffield.

THIS wheel trimmer (which sells at 2*s.*) will soon repay the outlay, as it is a handy addition to one's photographic resources. It has a bevelled hollow wheel (Sheffield made), and cuts wet or dry paper

equally well. The wheels and screws are interchangeable, and can be replaced at a small outlay. Again, owing to the wheel being hollow, with the cutting edge flat, it can readily be sharpened to a razor-like edge merely by rubbing on an ordinary oil stone. The Acme Print-trimmer is well and strongly made, and we can recommend it as a capital tool.

PLATES AND PAPERS.

By Dr. STIEFEL. London: Percy Lund & Co.

DR. STIEFEL'S book, which is apparently a translation, deals with the manufacture of the various sensitive papers in photographic use, and treats of their printing, toning, &c. Chapters of the book are also devoted to gelatine dry plates, development, &c. The work might have been condensed, for much of the information, particularly that referring to dry plates, is too meagre to be serviceable, and the translation here and there strikes us as crudely done; but, taken as a whole, the book is useful, and the information relating to the manufacture of collodion, gelatine, and albumen papers is such as is likely to be appreciated by many.

THE SOLAR COLLODIO-CHLORIDE PAPERS.

McGhie & Co., 75, St. Vincent-street, Glasgow.

MESSRS. MCGHIE & CO. have sent us, for inspection, specimen prints on the Solar collodio-chloride papers—"enamel surface" and "matt." The former have all the richness of image and beauty of tone we are apt to associate with good collodion prints, combined with excellence of gradation and purity in the lights. The latter—the "matt"—might easily be taken for surfaced platinum prints, so rich and velvety are the deposits. For the enamel the sulphocyanide and acetate baths are advised; for the matt, the acetate borax gold bath followed by one of potassium chloro-platinite. The directions for using the paper are full, but clear, and, judging by the specimens submitted to us, we have no hesitation in pronouncing the "Solar" collodio-chloride papers capable of yielding results of the highest excellence.

PORTRAITS BY ACETYLENE LIGHT.

John Edward Shaw, Huddersfield.

MR. SHAW, who had noticed our suggestion of last week relative to the adoption by photographers of the acetylene light for portraiture, sends us some portraits taken by the aid of that light. They are soft and harmoniously lighted pictures, equal in every respect to daylight work, and we are obliged to Mr. Shaw for giving us, by means of his excellent work, the opportunity of reiterating our hint to our professional readers to give acetylene their consideration.

ILLUSTRATED CATALOGUE OF THE ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

London: Harrison & Sons, 59, Pall Mall, S.W. Price 6d.

THIS is the second year that the Society has issued an illustrated catalogue, and the success of the experiment has been so marked that we are entitled to expect that the idea will secure permanent adoption. The catalogue this year is in many respects an improvement upon the first issue. A tastefully bound copy lies before us. Artistic head pieces, and a very effective style and arrangement of printing in the catalogue portion have been introduced, and it is interspersed with reproductions of twenty-two pen-and-ink sketches by Mr. Ralph H. Bayley, the cleverness, beauty, and artistic freedom of which we are the more able to appreciate from having compared them with the originals in the Exhibition. Over thirty half-tone blocks (by Meisenbach) of the exhibits are also given. These are very well printed, and the selection has been made with such conspicuously good judgment as to leave no room at all for objection. In recom-

mending each of our readers to purchase a copy of the catalogue, which has a present interest to, and is assured of a lasting esteem by, all lovers of photography, we append, on our own account, the compliment of recognition by name to Mr. R. Child Bayley, the able and devoted Assistant-Secretary of the Society, upon whom the labour of producing the catalogue has fallen.

News and Notes.

WOOLWICH PHOTOGRAPHIC SOCIETY.—The annual business meeting will be held at St. John's Lecture-room on Thursday, October 8, at 8 p.m.

THE DULWICH PHOTOGRAPHIC SOCIETY.—This Society's First Exhibition is to be held on November 12. The Judge is Mr. Leon Warnerke. There is an Open Class, 2*s.* 6*d.* entrance fee.

THE BRISTOL EXHIBITION.—This Exhibition will be held in December and January next. Entry forms may be obtained of the Hon. Secretary of the Bristol and West of England Amateur Photographic Association, 20, Berkeley-square, Clifton, Bristol.

MESSRS. PERKEN, SON, & RAYMENT advise us that their lease of the premises of their Oxford-street branch having lapsed by effluxion of time, that all business will be transacted from their headquarters, 99, Hatton-Garden, Holborn-viadnct, E.C.

THE PHOTOGRAPHIC CLUB.—The next weekly meeting of the Club will be held in the Club-room at Anderton's Hotel, Fleet-street, E.C., at eight o'clock on Wednesday evening, October 7. Mr. A. Horsley Hinton will deliver a lecture, with lantern illustrations, entitled *Pictorial Photography.* This lecture forms one of the series given under the auspices of the Affiliation of Photographic Societies. Visitors are welcome.

THE Brixton and Clapham Camera Club's Sixth Annual Exhibition will be held at the Clarence Rooms, Coldharbour Lane, Brixton, S.W., on Tuesday, Wednesday, Thursday, Friday, and Saturday, October 6 to 10. The members' classes are: A. Prints (direct or enlarged); B. Prints (open only to members who started photography since January 1, 1895); C. Lantern Slides in sets of four. A silver medal is offered for the best collective exhibit in Class A, and a bronze medal for the second best. Two bronze medals will also be placed at the disposal of the Judges for individual prints not included in the medalled collective exhibits. In Class B a bronze medal is offered for the best print, irrespective of subject. In Class C, a silver medal is offered for the best set of four slides, and a bronze medal for the second. The Open Classes are: D. Pictures (not medalled previous to September 21 at any open exhibition); E. Lantern Slides (not medalled previous to September 21 at any open exhibition). One silver and two bronze medals are offered in each class at the discretion of the Judges. The Judges are Messrs. F. P. Cembrano, jun., Colonel J. Gale, and E. J. Wall, F.R.P.S. A ticket of admission will be sent to each exhibitor. Intending exhibitors of apparatus may obtain full particulars on application to the Secretary, Mr. C. F. Archer, 1, Gaudeu-road, Clapham, S.W., of whom entry forms and further information may also be had.

THE Reading magistrates, on Friday, September 25, again investigated the remarkable charge of fraud against a man named Walter Henry Mayers, described as a photographer, who was charged with obtaining sums of money from a number of persons by fraud by means of advertisements inserted in a weekly periodical. The advertisement offered enlarged photographs at 7*s.* each, and also various prizes for those who could make the largest number of words out of the letters comprised in the title of a monthly magazine. Amongst the victims was Mrs. White, wife of a Baptist minister at Taunton, who stated that she sent Messrs. Mayers & Johnson, the supposed firm, 7*s.* and a cabinet photograph of her husband, and at the same time asked for the rules of the competition. She received a competition ticket, but she did not receive any enlargement of the photograph. She subsequently saw an advertisement having reference to a second competition, and promising two dozen *cartes.* She thereupon sent another 7*s.* and a photograph. She received an acknowledgment of the same, and then she wrote asking if words now obsolete, but used by old English authors, might be employed. The reply was that nothing but English pure and simple was to be used. Witness afterwards forwarded a list containing 6691 words. This was on September 6, but she received a letter to the effect that no list must be sent in before October 25. Other witnesses gave similar evidence, and Head Constable Tewaley stated that the prisoner was simply living in an attic at a cottage. Witness also found various documents, and saw the advertisements, in some of which it was stated that 1000*l.* was to be competed for, while another offered as a first prize a house in any part of the country valued at 400*l.* The prisoner was committed for trial.

Patent News.

THE following applications for Patents were made between September 16 and September 23, 1896:—

DRYING PLATES.—No. 20,280. "An Appliance for Quickly Drying Photographic Plates after being Developed and Washed." P. H. SAMUEL and J. SAMUEL.

KINETOSCOPIC PHOTOGRAPHY.—No. 20,307. "New or Improved Apparatus or Means by which Successive Photographs can be Produced." M. SAPPEY.

SLIDE CARRIERS FOR LANTERNS.—No. 20,346. "Improvements in and appertaining to Slide Carriers for Optical Lanterns." F. W. HUDLASS.

HAND CAMERAS.—No. 20,349. "Improvements in Hand Cameras." S. D. MCKELLEN.

RELIEF PHOTOGRAPHS.—No. 20,387. "Producing Photographs in Relief." Complete specification. T. C. MARCEAU.

ROCKING DISHES.—No. 20,430. "Improved Apparatus for Rocking Dishes or Trays for Photographic and other Purposes." Communicated by Valentin Zinsli, France. G. C. MARKS.

REFINING STOVES.—No. 20,695. "Improvements in Refining Stoves for Photographers." Complete specification. D. R. V. RIPER.

SHUTTER.—No. 20,768. "An Improved Photographic Shutter." G. HOUGHTON and W. A. EDWARDS.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK

October.	Name of Society.	Subject.
5	Bradford	*Scamper through Switzerland and Italy.* H. Hibbert.
5	North Middlesex	*Acetylene Gas.* Mr. Hoddle.
5	Richmond	*Photo micrographs.* T. Charters White.
6	Hackney	Members' Lantern Night.
7	Leeds Camera Club	*Enlarging.* Jno A. Hodges.
7	Photographic Club	*Pictorial Photography.* A. Horsley Hinton.
8	Liverpool Amateur	Lantern in Use for Testing Members' Slides.
8	Woolwich Photo. Society	Annual Business Meeting.

ROYAL PHOTOGRAPHIC SOCIETY.

SEPTEMBER 29.—Mr. T. Bolas, F.I.C., F.C.S., in the chair.

Dr. Lindsay Johson sent for inspection two *carte-de-visite* portraits, taken by a Congo native boy, one of a tribe of cannibals in the region of the Stanley Falls. The lad, who had been brought to England by a missionary, had, on his return to his native wilds, been presented by Dr. Johnson with a set of photographic apparatus, and he had now sent to England these specimens, which, the CHAIRMAN remarked, were very creditable.

The meeting was devoted to a demonstration of

THE APPARATUS IN THE EXHIBITION,

most of which has already been described in our columns. It included the Incanto acetylene-gas generator and a lantern fitting for acetylene gas (Messrs. Thorn & Hoddle); the "Memorandum" and 5×4 Frena cameras (Messrs. R. & J. Beck, Limited); the "Scientific" hand camera (Scientific Hand Camera Company); Sanderson's and the "Holborn Combination" cameras, fibre vignetters, printing frames, &c. (Messrs. G. Houghton & Son); "Censabul" focussing chamber and triple-lens finder (Messrs. Adams & Co.); process and enlarging camera, &c. (Messrs. Watson & Sons); several cameras and a "cyclist's" aluminium stand (Messrs. J. F. Shew & Co.); an improved lantern-slide camera (A. E. Biogemann); and a "Chariot Polyposes"—an apparatus for making photographic doubles, or photographs in which the same person appears in several positions, and taking the form of a rectangular frame sliding in front of the focussing screen and dry plate by means of an endless screw (M. Victor Bracq).

Mr. HUGH L. ALDIS, B.A., exhibited the Dallmeyer "Stigmatic" portrait lens, which has been fully described in the columns of THE BRITISH JOURNAL OF PHOTOGRAPHY. He said the principal feature of these lenses was their extreme rapidity, combined with perfect sharpness all over the field, there being complete freedom from spherical aberration at the very large comparative aperture of one-fourth the focal length. He did not think that any portrait lens had yet been introduced which would give such sharp marginal definition over a comparatively large angle. The novelty in construction lay in the fact that the flint lenses were all of lower refractive index than the crown lenses, and it was by this means that the correction for flatness of field, while retaining a very large aperture, had been attained. Spherical aberration could be introduced if required by partially unscrewing the back combination.

The CHAIRMAN remarked that the great advantage of the lens was that it got rid of astigmatism, which was an undesirable description of unsharpness under all circumstances.

Mr. T. R. DALLMEYER said the instrument was particularly suitable for stellar photography, for which purpose it would give crucial flatness of field over an angle of 40°. He thought Mr. Aldis was to be congratulated upon the production of a lens far in advance of the results of foreign competitors.

At the conclusion of the examination of the apparatus Messrs. Watson & Sons gave a demonstration of the X rays by means of a fluorescent screen, in which considerable interest was manifested.

The Hon. Secretary (Mr. Chapman Jones) was unfortunately unable to attend the meeting, as he was suffering from an attack of influenza, the announcement of the fact provoking a general expression of sympathy.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

SEPTEMBER 24.—Mr. A. Haddon in the chair.

Mr. P. EVERITT passed round a number of photographic copies of engravings which he had recently acquired, and which had been done some twenty or thirty years ago. They were printed on plain salted paper, and toned with gold. The salted paper (he was told) had been prepared in a special manner, so as to ensure a certain effect, and he proposed conducting some experiments with a view to discovering something about the procedure peculiar to this paper. He remarked on their state of preservation after such an extended period since their production, and held them as good evidence of the permanence that could be obtained in silver printing. He indicated one which would compare very well with a platinum print. They were copied with a Ross's

symmetrical lens of about 10 inches. He made a present of a print to the Association.

Mr. A. L. HENDERSON said that, in continuation of his experiments as to the cause of certain bands which developed up across plates exposed in particular dark slides, and which in some cases were apparently of an accelerating and, in others, a restraining nature, and the results of which he had communicated recently in a note before the Association, he had compared the effects of fresh with decomposed glue for fixing the cloth hinges. He procured some best Scotch glue, and soaked it in water, when, owing to decomposition, a lot dissolved out, the smell at the same time being unpleasant. With this he glued the hinges and exposed a plate, which showed, on development, an accelerating action. He then precipitated some of the glue with alcohol, washed it in water to free it from the alcohol, and dissolved it at a low temperature. A plate was then subjected for a long time to the influence of a piece of cloth treated with this glue, but without any action whatever, showing at once that the use of decomposed gelatine was decidedly bad. He therefore recommended the precipitation of the glue as above as a means of overcoming the effect produced by exposure to the moisture of the air.

Mr. HADDON said by this process one practically prepared gelatine from the ordinary glue, so why not use gelatine?

Mr. EVERITT said that known as French glue, which was of an amber colour, would, from its great hardness, be superior, as it would not attract moisture so readily.

In consequence of the retirement from office of Mr. Everitt, Mr. T. E. Freshwater will assume, until the next annual meeting, the post of Hon. Secretary, while Mr. E. J. Wall has consented to serve in the capacity of Hon. Recorder until the same date.

PHOTOGRAPHIC CLUB.

SEPTEMBER 23, Mr. E. W. Foxlee in the chair.

Captain HAYES, who was present as a visitor, showed an interesting series of instantaneous photographs of horses. These photographs illustrated the various phases of the canter of an Arab polo pony. They were taken consecutively with a Newman & Guardia camera, fitted with a Zeiss lens working at *f*-6·3, and fitted with a Celeritas shutter working between the lenses at a maximum speed at $\frac{1}{100}$ second. The object of the photographs was to demonstrate that the motion of both the near and the off legs of a horse is similar, and Captain Hayes had succeeded in happily choosing the exact moments at which to make the photographs. He lays it down as a rule that all his pictures of horses shall be made against a clear sky and at right angles to the line of sight, and at a distance of twelve yards from the animal. He stated that he used Paget XXXXX plates, and that he found it advisable with very short exposures to commence development in absolute darkness. Captain Hayes was anxious to have the opinion of the members upon the relative suitability of a focal-plane shutter and such a one as he was using, and suggested that some one might be disposed to take up the question and make a series of practical tests with apparatus identical in all respects except the shutter.

Mr. FRY deprecated such a test. He said he would prefer to rely upon a calculation of the efficiency of such instruments by mathematical means.

Mr. MACKIE supported this position.

Mr. BRIDGE sympathised with Captain Hayes's preference for a practical test.

Mr. FRY said that he had had the advantage of seeing Mr. Newman's apparatus (which he believed he had invented as well as constructed) for the purpose of testing the speed of shutters. He believed that, if the matter were referred to him (Mr. Newman), his instrument would make all the measurements and give all the facts which the Captain required.

Mr. FOXLEE raised several technical points, referring to the distortion, which was, in theory, the weak point of the focal-plane shutter.

Captain HAYES said that his remarks must not be taken in any sense to apply to the makers of apparatus, but simply to principles involved.

Mr. Walker, of Leeds, a visitor, was welcomed by the meeting.

Mr. FOXLEE said that it used to be the habit of the Club to extend an open invitation to country photographers visiting London during the time that the Exhibition of the Royal Photographic Society was open. He thought that the Club (although it was well known they were always pleased to see country photographers) might, by a letter from their Secretary through the press, offer a special invitation at this time.

The SECRETARY said that he had no doubt every one present would agree with Mr. Foxlee, and that he would send a letter to the editors of the several papers.

The meeting then proceeded to the subject of the evening,

HALATION.

Mr. DRAGE mentioned that recently he had seen a recommendation to place one dry plate behind another for the purpose of minimising halation.

Mr. MACKIE said he should like to know how the author of this idea thought it would act. The rays which passed through the back of the plate were not those which caused halation.

Mr. FRY said that the first principle to be observed in backing a plate was to have the backing in optical contact with the back of it. He would expect the method suggested to act detrimentally if at all.

Mr. HAES asked for a definition of halation.

Mr. MACKIE replied that he defined it as the effect upon a film caused by a reflection of certain rays of light from the back of the plate, but many things were called halation which were really a correct reproduction of effects as seen by the eye. In his opinion a full exposure and well-restrained development tended to minimise the effects of halation. The idea was well supported by the results in the Watkins Developing Competition.

Mr. NESBIT had found just as much halation with films as with plates. He thought that halation was due quite as much to the lateral or spreading action of light in the film as to the causes which Mr. Mackie had referred to.

A brief discussion ensued upon the presence of ladies at the Club's Travellers' Nights. The consensus of opinion among the members present was that ladies should be welcomed on those evenings, but that the ordinary regulations as to smoking would be in force.

Croydon Camera Club.—The meeting on Wednesday, 23rd ult., was preliminary to the inauguration of the winter session, which begins on October 7, and which promises to be unusually interesting. Important and useful lectures on various photo-technical matters have been arranged to be given by Messrs. W. Friese-Green, A. Haddon, Horsley Hinton, A. Bellin, the Rev. F. C. Lambert, and other distinguished photograpers. The public lantern shows will be held on the same basis as has given such great satisfaction during the past six years. Amongst the subjects of the first few technical lectures will be a complete demonstration of the latest methods of *Shadowgraphy with X Rays*, also *The Utilisation of the Acetylene Light for Photography*. Mr. Burn was bearer of an invitation from the Dolphin Swimming Club for a party of members to attend and takes flashlights of the competitors at the forthcoming costume entertainment. It was arranged to ask certain members skilled in the above branch of photography to accept the above invitation. The election of the following new members was notified as having taken place since the last meeting:—Mr. H. L. S. Richardson. LL.M., B.A., and Mr. C. Nightingale.

Dulwich Photographic Society.—Mr. H. C. Jackson in the chair.—The Hon. Secretary, Mr. H. J. Ellis, produced a letter from Sir J. Blundell Maple, M.P., the President, expressing his regret at the inability of Lady Maple and himself attending the first Exhibition of the Society, to be held at the Constitutional Club, East Dulwich Grove, on Thursday, November 12. Sir J. Blundell Maple kindly enclosed a cheque towards the expenses of the Exhibition. Mr. S. Withers gave a most successful demonstration of lantern-slide making, the slides afterwards being thrown on the screen, the lantern being kindly lent by H. Jennings, Esq., late proprietor of the historic Greyhound Hotel, Dulwich. Slides were afterwards exhibited by Messrs. F. Thomas, F. F. Thomas, E. W. Beer, G. E. Smith, and H. J. Ellis. The next meeting was arranged for Tuesday, October 6, when the Hon. Secretary will give a demonstration for beginners on *Intensification and Reduction*.

Hackney Photographic Society.—September 22, Mr. R. Beckett presiding.—Lantern Night. A very fine series of slides on the subject of *Travels in Sicily* was shown by Mr. A. L. HENDERSON. The slides were good both in quality and subject, and Mr. Henderson's description was most interesting. Members' slides were shown by Messrs. Guest and Walker.

North Middlesex Photographic Society.—September 28, Mr. S. E. Wall in the chair.—Mr. G. A. Barton, 49, Sussex road, Holloway, and Mr. G. F. Humbly, 2, Gresby-road, Hornsey-lane, were nominated for membership. Messrs. A. J. D. Forster and Henry Crouch were balloted for and duly elected. Mr. E. DOCKREE, of the Brixton and Clapham Camera Club, then read a very practical paper on

LANTERN SLIDES AND THEIR PRODUCTION.

He said he always used gelatino-bromide plates, and maintained that as fine results could be obtained on them as on collodion, with the added advantage of rapidity, which was necessary when slides were produced by reduction in the camera. He always reduced his slides, and said a finer result was so obtained than by contact printing. You could obtain what colour you preferred by regulating the amount of bromide and carbonate of ammonia, giving longer exposure the warmer the tone required. He sometimes found a redeveloper useful, and gave a formula: A. Pyro, 6 grains; citric acid, 15 grains; distilled water, 1 ounce. B. Silver nitrate, 30 grains; distilled water, 1 ounce. Take sufficient of A to cover the plate and add a few drops of B. A thorough washing to remove hypo was necessary before using this. A clearer was sometimes necessary. and hypo, with a few drops of ferridcyanide of potash was very good, but he thought landscapes were sometimes improved by a slight veil. He got all his clouds on the same plate by first using a weak developer and then a stronger restrained one. After a very fair discussion, he passed through a magnificent collection of slides, which were very well received.

Bradford Photographic Society.—On September 21, 1896, Mr. P. R. SALMON delivered a lecture on

FIGURE STUDIES AND PICTORIAL PORTRAITURE

in the Club-rooms, Sunbridge-road. Mr. Salmon, who is well known in photographic circles, is a painstaking worker and constant exhibitor of *genre* studies, managed to entertain his hearers for over two hours, and to impart considerable instruction at the same time. The pictures thrown upon the screen were entirely the lecturer's own work, and included some capital studies of young ladies representing *Little Lord Fauntleroy*, *We are Seven*, *Lucy Gray*, *Song of the Shirt*, &c. At the close of the lecture, a vote of thanks was proposed by the Chairman, Mr. Walter Booth, to which Mr. Salmon responded, mentioning the fact that he was leaving the town, but he hoped that that would be by no means his last lecture before that Society.

Leigh Photographic Society.—The Annual General Meeting was held on the 24th inst. The President (Mr. M. F. Burrows) presided.—The balance-sheet was passed, with the balance of 1*l.* 16*s.* 8*d.* in hand, and the officers elected were:—*President:* Mr. M. F. Burrows, J.P.—*Vice-Presidents:* Dr. Joseph Jones, Messrs. Robert Leigh, T. Lee Syms, James Ward, B.A., J. H. Stephen, W. Hampson, and T. Peters.—*Committee:* Messrs. J. Berry, T. G. Hirst, W. Crouchley, T. Mercer, and P. Seddon.—*Treasurer:* Mr. T. Haddock.—*Secretary:* Mr. W. R. Moore. Rules were discussed, and arrangements were made for the syllabus.

Liverpool Amateur Photographic Association.—September 24, the President (Mr. J. Sirett Brown) in the chair, when eleven new members were elected.—The medal offered by the President in the Dolgelly Excursion Competition was presented to the winner, Mr. F. Anyon. The President drew the attention of members to some of the principal items in the winter programme,

and announced that a complete list wou'd shortly be issued. Dr. LLEWELLYN MORGAN then delivered his lecture, entitled

SUMMER AND WINTER VISITS TO THE ENGLISH LAKES,

the places visited including Windermere Lake, Ambleside, Langdale Valley, Rydal Water, Grasmere, &c. The lecture, which was very interesting, was illustrated by about 130 lantern slides from negatives taken by the lecturer. A hearty vote of thanks to Dr. Morgan concluded the meeting.

FORTHCOMING EXHIBITIONS.

1896.	
Oct. 2-Nov. 7	Photographic Salon, Dudley Gallery, Piccadilly. Alfred Maskell, Dudley Gallery, Piccadilly.
,, 2-Nov. 12	Royal Photographic Society. R. Child Bayley, 12, Hanover-square.
,, 6-10	Brixton and Clapham Camera Club. C. F. Archer, 1 Gauden-road, Clapham, S.W.
November 12	Dulwich Photographic Society.
December 3, 4.....	Aintree Photographic Society. E. P. Heron, 2 Tilney-street, Orrell Park, Aintree, Liverpool.
Dec. 1896-Jan. 1897	Bristol International.

Correspondence.

☞ *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

"SOMETHING FOR NOTHING."

To the EDITORS.

GENTLEMEN,—I enclose you "a puzzle" in the form of a typed letter, received a day or two ago. What is it? and what does it mean?

I was under the impression a picture critic went round the Exhibition or Exhibitions, and picked out there such examples as were thought desirable, and said what there was to be said regarding their faults or otherwise for the benefit of the public, exhibitor, or critic. It would seem I have been mistaken, my own impression of the effusion in question being that it is a piece of "unadulterated cheek," to put it mildly.

Why should I, or any other exhibitor, be called upon to supply "copy" for this F.R.P.S., F.G.S., and the rest of it—copy for which *he is to be paid?* and, forsooth, after going to the trouble and cost of producing them, they are to be, at his sweet discretion, reproduced in either of the publications named by him, or in others of a similar character.

Evidently he is a man of business, for, enclosed with this demand, is a slip advertisement of some book or other written by himself, and on sale; but why it should be sent—the call for print or the advertisement—is a puzzle to

A DISGUSTED RECIPIENT.

September 23, 1896.

"34, *Birdhurst-road, Croydon, September* 16, 1896.

"DEAR SIR,—I have been requested by the respective editors of the (1) *St. James's Budget* and the (2) *Photographic Times* of New York to supply illustrated critiques of the Royal Photographic Society's and the Salon's Exhibitions.

"If you are exhibiting anything likely to be suitable for reproduction, as aforesaid, I should be much obliged by your forwarding me a print, or prints, *with as little delay as possible.*

"Inasmuch as the usual custom, where Exhibition pictures are reproduced along with a critique, is that no fee is offered, unless you explicitly state that you require payment and name the sum, none will be made.

"Any prints sent in will, if suitable, be, at my discretion, reproduced in either of the above-named publications, or in other publications of a similar character, accompanied by a critical notice of the Exhibition, unless I am specially advised by you to the contrary.

"Believe me,

"Yours very faithfully,

"HECTOR MACLEAN.

"P.S.—For the information of such as may not be acquainted with the *Photographic Times*, it may be stated that it is the leading illustrated monthly publication in the world devoted to photography, being notable for the high class of the photographs it reproduces, and for the perfection with which such reproductions are printed. "H. M."

[Having brought the foregoing letter to the notice of Mr. Hector Maclean, he sends us the following reply.—EDS.]

To the EDITORS.

GENTLEMEN,—The letter of "A Disgusted Recipient" shows all the malevolence and inaccuracy which we look for from the hateful anonymous traducer.

Fortunately, along with the above letter, the typed communication of mine referred to is also printed. It supplies a complete refutation of the gratuitous mis-statements of this person, whose syntax is so curious.

By inspection of the last-named document it will be seen that, contrary to your correspondent's allegation, photographers are distinctly invited not only to name the sum they want for permission to reproduce, but also to indicate the publications which they would like their prints to appear in.

At the same time there are many exhibitors who, aware of the extra trouble and expense involved in arranging for illustrated *critiques*, and further, recognising that such articles serve to popularise the photographer's work, to advertise the Exhibition, and, generally, advance the practice of pictorial photography, are desirous of giving every facility for their prints to reach a yet wider circle than the visitors of an exhibition.

Let me take the opportunity of emphasising that it is consequent on such reckless abuse as that under consideration that many who would at the present moment be useful and brilliant, active members of the photographic commonwealth have gone into retirement, fearful of being subject to recurrent showers of ill-bred impertinence.

Personally, I usually take such spiteful attacks for what they are worth, which is nothing. In the present instance I must, however, make an exception, for, thanks to your correspondent, many photographers will be for the first time made aware that I am open to receive prints for the purpose described.

Thanking you for the courtesy extended whereby I am enabled to promptly answer the aspersions cast upon me,—I am, yours, &c.,

September 26, 1896. HECTOR MACLEAN.

THE POISONS EXCITEMENT.

To the EDITORS.

GENTLEMEN,—Your correspondent, "Pharmacian," states that the treatment of this subject in your pages is calculated to afford considerable amusement. I must congratulate him upon his amusing contribution.

He asks, "What is a photographic dealer?" He then refers to "tinkers, tailors," &c., "et hoc genus omne, cheerfully innocent of chemistry, optics, mechanics, and other collateral sciences," the latter part of which applies admirably to the druggists who go in for the photographic trade on the "sell-the goods" principle, but who frequently lack the "smattering of photography." A druggist who, some little time ago, thought of taking up the "photographic trade," asked me one day what was the difference between dry and wet-plate photography. So many of his customers asked him for hypo that he was anxious to know what it was used for. He went in for photography himself some years ago, but never used hypo.

Mr. "Pharmacian," like many other of your correspondents, has tried to drag a red herring across the track of the discussion, and divert our attention from the real points at issue, which I take it are these:—

Firstly, why should the name "chemist" be appropriated by druggists, the majority of whom have little knowledge of chemistry, and denied to those who have a special knowledge of the subject? A complete, full, and particular knowledge of the *materia medica* does not make a chemist, and even many doctors willingly admit that their own knowledge of chemistry, properly so called, is not extensive.

Secondly, why should druggists have a monopoly of the sale of poisons, while others to whom their sale is important should not be allowed to sell them at all? If druggists want to monopolise the sale of opium, they can do so; but there is no reason why they should also monopolise the sale of certain other poisons for which they have practically no demand, and which many of them do not keep.

Thirdly, why is the schedule of poisons so ridiculously incomplete, and, if chemists are so anxious to protect the public, why don't they take steps to have it properly revised? They are making a great fluster over the question of the sale of carbolic acid, *which is an important article of commerce*, but say nothing about other unscheduled poisons, *a monopoly in which would not be so valuable.*

Fourthly, why does the Pharmaceutical Society allow the Poisons Act to be evaded by the free sale of patent preparations containing scheduled poisons? and why do druggists themselves so frequently omit to carry out the regulations of the Poisons Act? How is it that in almost every household we find bottles of spirits of salts and oxalic acid, which are used for cleaning purposes, and can be obtained without any trouble, in spite of the fact that they are frequently used by suicides? I have often bought scheduled poisons from druggists and others, and have never signed a poison book in my life.

A *photographic dealer* once refused to sell me some potassium ferricyanite, because he did not personally know me, and a well-known firm of *manufacturing chemists*, who knew me well as a customer, would not let me have an ounce of mercury bichloride unless I brought a friend as a witness to the transaction. Having no friend handy, I went to a *pharmaceutical and photographic chemist*, who knew me equally well, and simply told him to send it, *which he did.* If ever there is any difficulty about obtaining mercury bichloride, we can always get calomel and convert it.

Our friends the druggists should put their own house in order before interfering with, and prosecuting, other people. Judging by their letters to you, however, they seem to be remarkably well satisfied with themselves and with their own accomplishments; but, apparently, other people—photographers, doctors, and the more educated members of the British public—do not have quite such an exalted opinion of them. The way in which many of them do business is not calculated to inspire confidence. Why, when we take a prescription to be made up, does the pharmaceutical "chemist" ask for details of the particular ailment the medicine is intended for? A doctor once told me to get a certain pre-

paration from a druggist, and also instructed me to tell him *to give me the genuine article, and not something of his own composition!* Why did the doctor give me that advice? and, when I acted upon it, why did the chemist smile so mysteriously? A short time ago an eminent London surgeon remarked to me that no druggist could resist the temptation of becoming a quack. What did he mean?

We have heard a good deal about "cutting" chemists; I have never come across one of this variety. One tried very hard once to get eighteenpence a gallon out of me for some distilled water, but had to put up with eightpence, some plain speaking, and the loss of my custom. At another time I was charged eighteenpence for a bottle of medicine, and a few days after the same man made an audacious attempt to get half-a-crown out of me for a second bottle of the same stuff, but failed ignominiously. His excuse was, that *he had forgotten what he had charged me the first time.* This sort of thing is a common experience; it cannot be described as "cutting," but might, with every excuse, be described as —well—something else.

Druggists, or pharmaceutical "chemists," are, generally speaking, peculiar beings, and they manifest their knowledge and conduct their business in peculiar ways which do not somehow appeal to me, which ways also are quite different to those of other tradesmen. They have a failing that is, unfortunately, rather common to scientific men, that is, bumptiousness, the exhibition of which is generally amusing. Their pet schedule of poisons, as a document, is also amusing; it is superior even to the list of infectious diseases which includes croup and leaves out measles.—I am, yours, &c. NEMO.

September 25, 1896.

THE PHOTOGRAPHIC CLUB: AN INVITATION.

To the EDITORS.

GENTLEMEN,—I shall feel obliged if you will kindly allow me to make your columns a medium for inviting any provincial photographers who may be in London for the Exhibition of the Royal Photographic Society to the meetings of the Photographic Club.

We meet every Wednesday evening at eight o'clock at Anderton's Hotel, Fleet-street, E.C. The following is our programme for October, and we shall be pleased to welcome any of our country friends who may favour us with a visit:—

October 7.—*Pictorial Photography*, with lantern illustrations. Mr. A. Horsley Hinton. October 14.—Demonstration. *Acetylene Gas for ordinary use and lantern projection.* Mr. C. Hoddle. Members' lantern slides, &c. October 21.—Members' Open Night. October 28.—Travellers' Night. *Switzerland*, with lantern illustrations. Mr. T. Charters White.

Thanking you in anticipation, I remain, yours, &c.,

F. A. BRIDGE, *Hon. Secretary pro tem.*

Dalston-lane, London, N.E., September 26, 1896.

Answers to Correspondents.

*** *All matters intended for the text portion of this* JOURNAL, *including queries, must be addressed to* "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2, *York-street, Covent Garden, London. Inattention to this ensures delay.*

*** *Communications relating to Advertisements and general business affairs should be addressed to Messrs.* HENRY GREENWOOD & CO., 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:—

Thomas Bourke, 213, South-street, Perth.—*Photograph of Right Rev. James Smith, bishop of Dunkeld (cabinet, half-length).*

John Spark, 49, York-place, Perth.—*Two photographs of Rev. John Addie, minister of Wilson U. P. Church, Perth. Two photographs of Rev. P. A. G. Clark, minister of Free West Church, Perth. Photograph of Rev. John Symon, minister of Free St. Paul's, Perth.*

RECEIVED.—MOULT BROTHERS, NORMAN, P. STOW, C. H. PRICE, HELIOS. In our next.

STEREOSCOPE.—We will endeavour to get the information for you by next week.

ALFRED WILDMAN and others who send us copies of West of England newspapers referring to Mr. Bennetto's "colour photography" are thanked.

DETENTION OF NEGATIVES.—G. H. STANFORD. A death in the family is, perhaps, responsible for the delay. Can you not get a London friend to call upon the firm for you?

BOOK ON PROCESS WORK.—PROCESS WORKER says: "I would like to know the best book I can purchase on process work."—In reply: *The Half-tone Process*, by J. Verfasser, published by Percy Lund & Co., Amen-corner, E.C.

ASSISTANT *versus* EMPLOYER.—PADDY. To recover the amount claimed, you must proceed in the County Court. We are not sure that you would be successful, and you had therefore better lay your case before some respectable solicitor.

FLASHLIGHT.—F. W. TARSELL. We would suggest the use of two or three flash lamps working simultaneously. Messrs. Marion & Co., we believe, supply such an arrangement, and probably other dealers. You will find a few useful hints in an article published in the JOURNAL of September 11, and in the present number.

LANTERN SLIDES FROM THE OLD MASTERS.—F. B. J. says: "I want some lantern slides of some of the pictures in the National Gallery. Should I be doing wrong in copying some of the photographs of them now being published, as there can be no copyright in the pictures now?"—Yes, doubtless, you would. Although there is no copyright in the paintings, there is in the photographs made from them. You will be quite safe if you copy the paintings, but the reverse if you copy the photographs.

MOUNTING PRINTS. BROMIDE PAPER.—C. F. WYNNE asks: "Would you kindly inform me: 1. Is there any method of removing albumen prints from mounts besides the ordinary soaking in water—mountant made from ordinary starch? 2. I have some bromide paper, Marion's and Ilford, in stock for the past twelve months, kept in a dry place, free from strong light, &c. Now, that I wish to do some enlargements, would like to know from you as to its keeping qualities, if some should be in good condition."—1. The method suggested is the best. 2. Try a piece of the paper, and see if it is in good condition. If it has been properly kept, we should expect it would be found so.

AGREEMENT.—OPERATOR writes: "I made a three-year agreement with the house I am now with, which expires at Christmas. There is a clause in the agreement that I am not to set up in business, or enter the service of another photographer, within half a mile of the studio under a penalty of two hundred and fifty pounds. Now, there is a house to let within a few doors off which I can have, and put up a studio. Can the penalty be enforced, as, if not, it is a good chance for me?"—Certainly it can, and it would be very dishonourable on your part to make an agreement and attempt so deliberately to break it. If you pay the two hundred and fifty pounds, of course you will be at liberty to do what you chose, and no one can find fault with you.

RETOUCHING MEDIUM.—RETOUCHER says: "Mr. Harold Baker's remarks on retouching medium are very interesting. I notice that he does not refer to the mixture of "turpentine and resin" by themselves. Can you tell me what objection, if any there is, to its use, as I know several professionals who use it and prefer it to any other? Some time ago you promised us an article on the "tooth" that is frequently found on the film of a negative without any preparation at all. I have watched for it, but in vain."—The mixture of turpentine and resin is very good indeed. The only objection to it is that, if the negative is varnished, the retouching is disturbed, and, in some cases, entirely removed. The promised article will appear shortly.

TONING DIFFICULTIES.—PERPLEXED PRINTER writes as follows: "I am very perplexed at times over the uneven toning of my prints. I have used several brands of P.O.P. in my time with success, but the firm I am with now use the —— brand. In dry weather it works splendidly, but in damp or hot weather I cannot be at all certain that my prints will be passable. I follow out the maker's instructions to the letter, but I get very uneven tonings, such as yellow half-tones and very red shadows. If I tone the prints for the correct colours in the high lights, the depths are not toned enough, and, if I tone for the correct colours in the shadows, the high lights turn a muddy, yellowish colour. My predecessor used to get a splendid even warm tone, but I know he used a formula of his own. I am in fear of losing my berth if this continues, but try as I may I cannot alter it. Could you help me in this? I have tried using more gold, but that gives a too black a tone, and again a little less gold, but that seems worse than ever. Trusting you will answer this as soon as possible." — Personally we have had no experience with the brand of paper named. Possibly another toning formula than that recommended by the makers would answer better in our correspondent's hands. Probably the employer would substitute one or other of the well known brands for that now used if our correspondent could get on better with them.

EXPENSES IN LAW-SUITS.—EIKONOGEN says: "I have a question that I should like your opinion on. It is this: I have been doing some photographing for a client. He has paid what I charged; but I and my assistant had a subpœna to attend a law case in the London Courts, these photographs having been taken for one side, to show what ought to be done or what ought not. These photographs were for the Judge to see, and I and my assistant were there to answer any question with regard to them, also to swear to the taking of them. But what I want to know is, What is the usual fee in such circumstances? I must explain. I do my own operating, and had to leave my studio without having any one to carry it on. Thus, wanting my assistant operator as well, I arranged as well as I could, but had no one who could take a photograph, and, of course, there was some loss; and it was of no use engaging any one, as the case went for so long, expecting to come on, first in a few days, then weeks waiting. Well, I and my assistant were in London two days, and I charged a fee of 2*l.* 2*s.* for myself per day, and 10*s.* 6*d.* per day for my assistant; for hotel expenses, 21*s.* per day for self, and 10*s.* 6*d.* per day for assistant, they allowing railway fares and cab fares. Now, when I sent in my account for this, they write me that I am not to have any more than 21*s.* per day, including fee and hotel expenses, and 10*s.* 6*d.* for assistant. This seems a ridiculous sum for me to receive for my time and inconvenience, and they say they need really only pay me 16*s.* a day, as that would be all the Court would allow. This for leaving my business and going to London to attend at the Court. They say that I cannot claim as a professional, but I have always been under the impression that photography was a profession."—In reply: It is, and always has been, a vexed point as to whether it is a *profession* or not in law. Our correspondent should have arranged terms with his client before he undertook the work. That is what is done by most experts in photography in similar cases. The charges made seem reasonable; but, whether they can be enforced, we cannot say. We presume our correspondent has been engaged on the losing side, hence the demur to the charges.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1901. Vol. XLIII.—OCTOBER 9, 1896.

Contents.

OUR FORTHCOMING ALMANAC.

The British Journal Photographic Almanac for 1897 is now in an advanced state of preparation. A feature of the volume for the past thirty years has been the co-operation of numerous friends and readers of the Journal, and the Editor takes the opportunity to express the hope that the support so kindly placed at the disposal of his predecessors may be continued to him.

We especially invite contributions on topics of practical interest, and should feel obliged if the articles and any accompanying sketches are sent to us at the earliest possible date.

Secretaries of Societies, and especially of those established since the appearance of the last Almanac, will oblige us by forwarding lists of officers and other details for inclusion in the Directory of Photographic Societies, in order that the list may be made as complete as possible.

The Publishers wish us to remind intending advertisers that the announcement pages of the Almanac are filling rapidly, and that, to ensure insertion and good positions, orders and copy should reach them without delay.

EX CATHEDRÂ.

We are informed that the matter of the Research Fund of the Photographic Convention of the United Kingdom was brought to the notice of the Convention Council last week, with the result that the Research Grants Sub-committee was dissolved, and the Council itself was empowered to make grants in aid of original research, and to invite suitable persons to take up the work. With commendable promptitude the Council at once decided to invite Messrs. Haddon and Grundy to undertake an investigation into the subject of the influence of the strength of the hypo solution on fixation—in other words, the exact strength of hypo solution necessary for perfect fixation.

* * *

We are also pleased to announce that Mr. R. P. Drage has consented to retain the Secretaryship of the Convention. The labours of the position are, at times, extremely heavy, and such as are calculated to damp the ardour of the most enthusiastic official. In future, however, much of the work entailed by the organization of the Convention meetings will probably be shared by individual members of the Council, or possibly Sub-committees, so that Mr. Drage will be relieved of much of the heavier routine and other work, while still retaining the General Secretary and Treasurership. We sincerely hope that, when the details of this highly desirable scheme come to be settled, there will be no lack of willing volunteers to support Mr. Drage.

* * *

The balance-sheet of the Convention Leeds meeting is printed in another part of the Journal, and discloses a very satisfactory state of affairs. The accumulation of money by such an institution as the Convention is obviously not a matter of urgency beyond a point where something more than solvency is assured, and therefore, if future meetings of the Convention are profitable, and the Research scheme continues in active operation—both of which things we hope and believe will come to pass—the reproach that the Convention does nothing for photography will no longer hold good—nay, more, visitors to these pleasant annual gatherings will have the rare happiness of feeling that, in their enjoyment, they are contributing something towards the progress of photographic science.

* * *

We are informed that the secret process for preventing

halation that was recently referred to in these columns, and for which a charge of 5*s.* was asked, consists of the following device: In front of the lens an opaque body is temporarily placed, or held, so that, upon the portion of the plate that is receiving the most brightly lighted, or halated portion of the picture, the illumination is reduced. Will some purchaser say if we have been rightly informed?

* * *

The aggrieved assistant who cannot obtain the return of specimens he has sent when answering advertisements makes his appearance several times during the year in these pages. One of the unfortunate class again addresses us: "You will see in your last week's issue that I was advertising for a situation as operator, dark-room manager, and retoucher, in reply to which I received several letters, asking for particulars and proofs of my work, which I duly sent to them, and up to now I have not received a reply to my letters, nor have my proofs been returned. Do you think, Sir, that these men are answering advertisements appearing in your paper in order to gather a collection of photographs, which their own incompetency will not allow them to produce for themselves, and, in consequence, depriving such as myself of every available specimen from which he hopes to procure a situation? Perhaps I have not given them time to return proofs. Any how, there is a man who, is advertising this week, and is still holding my proofs. If he is seeking the services of other men, why not return my work? His letter is headed by his name, &c., stamped with an indiarubber stamp, which has the appearance of a memorandum got up for the occasion. If he requires so many assistants, and has such an extensive business, why hasn't he printed memoranda? I shall be glad if you will kindly advise me what to do in these matters."

* * *

Our advice to photographic assistants when submitting specimens has been so often given in our columns that we should have imagined there was hardly one of the class who was unaware of our reiterated admonition to write their names and addresses across the photographs with which they are temporarily parting. If this does not always ensure their return, it at any rate interposes an obstacle to the dishonest use of photographs illicitly obtained. We shall at all times be happy to hear from assistants whose specimens are wrongfully detained, and will do our best, if stamped addressed envelopes are enclosed, to secure the return of the photographs. At the same time, we feel it desirable to here state that we have many times taken up cases of alleged improper detention which, upon investigation, have turned out to be caused by the carelessness of the sender of the photographs in failing to give facilities for their identification and return.

DIRECT TRICHROMATIC HALF-TONE NEGATIVES.

That there is a much greater interest being taken at the present time in three-colour work is evident, and the fact that, commercially, the half-tone process is practically the only one used naturally suggests the question as to whether such half-tone negatives cannot be prepared direct in the camera, and thus one operation, if not considerable time, be saved.

Wet collodion probably still holds its own for half-tone negative-making, although, it is being somewhat hardly pushed by the photo-mechanical dry plates, and for three-colour printing, it is absolutely essential, if the former be used, that the plates should be rendered colour sensitive. There is no difficulty in this if certain requirements are fulfilled, and which entail not only considerable care, but also special preparation of the collodion and bath.

Probably every commercial collodion is intended for use with bromo-iodide salts, and it is a fact, well established by the researches of Vogel, Eder, and Schumann, that the iodides do not take kindly to colour sensitising; therefore it is necessary, even if one purchases the collodion, to replace the iodiser by a bromising solution. On the other hand, if the bath or collodion is quite free from iodide, the sensitiveness of the plates is so low as to necessitate an increase of exposure, without any screen, of at least three times that of a normal bromo-iodide wet plate.

Probably the best-known orthochromatic wet process is that suggested by Vogel in 1884, and which has remained almost unaltered to the present time—unaltered and unamended because, in many cases, it has been replaced by the orthochromatic collodion emulsion and gelatine plates.

The raw collodion is best prepared from celloidin, because one can rely upon obtaining it always of constant composition, and free from any traces of acids, which would seriously interfere, if not totally destroy, the action of the dye. A two and a half per cent. collodion solution is to be preferred, though, for those who prefer a thin, flowing collodion, this may be reduced to two per cent., but it will be found, when the bromiser is added, that the more viscous collodion is not too thick.

The bromiser is made by dissolving 200 grains of cadmium bromide in 5 ounces of absolute alcohol, and filtering.

One part of this bromiser is mixed with three parts of a two and a half per cent. collodion. If only a two per cent. collodion be used, then the cadmium bromide must be reduced to 160 grains for the 5 ounces.

The silver bath is not quite of the usual formula, and, in fact, it must at once be recognised that a fresh silver bath must be made up and reserved for these colour-sensitive plates alone; the ordinary silver bath, whether new or old, is practically useless, and, further than that, if it is used, cannot be again used for ordinary work.

The best silver bath for this work is:—

Silver nitrate	480 grains.
Distilled water	10 ounces.
Solution of potassium iodide (one per cent.)	14 ,,
Glacial acetic acid	*quant. suff.*
Absolute alcohol	½ ounce.

So far, there is no particular difficulty; but we now have the question of colour sensitising to consider. We are dealing with a silver haloid, which is sensitive mainly to the dark blue about G, whereas we require a sensitiveness extending entirely through the spectrum. In its unorthochromatised condition, this collodion will give us very well the negative from which we shall prepare our yellow-printing plate, and, if a screen of methyl violet is used, it will be quite satisfactory, with one exception, to which we shall refer after. The violet screen may be prepared by making first a 1 : 300 solution of methyl violet, and adding from 40 to 50 minims of this to every ounce of plain enamel collodion.

To sensitise the plate for green and yellow, eosine (yellowish) is the most satisfactory; and the solution is prepared as follows: 4 grains of pure yellowish eosine should be added to 3 ounces

of absolute alcohol, well shaken, and allowed to stand at least three days, with constant shaking, and should then be carefully filtered. To sensitise the collodion, five per cent. of this dye solution should be added to the bromised collodion.

For use with this collodion a green screen is made, either by adding 80 minims of a 1 : 200 alcoholic solution of malachite green to every ounce of enamel collodion, or, preferably, by using half this quantity of naphthol green and naphthol yellow alcoholic solution.

The third negative, which will give us our printing plate in blue, is the most troublesome to make, for it is difficult to satisfactorily sensitise the collodion for red. Cyanine is the most satisfactory, in that clearer prints are obtained, though it is doubtful whether cærulean S could not be used with better effects, the only point being that acids set free sulphurous acid from this compound, which might naturally act prejudicially, not only on the silver bath, but also on the clearness of the resulting negative.

Cyanine may be used in exactly the same way as eosine, and, in fact, equal quantities of the two dye solutions should be mixed and added to the collodion in the proportion of five per cent. of each.

With this collodion an orange red screen should be used, which may be prepared by using about 40 minims of 1 : 500 solution of aurantia, and 40 minims of 1 : 500 solution of chrysoldine extra to the ounce of enamel collodion.

The formulæ given for these screens are but approximate, and they must really be adjusted by means of a spectroscope.

To sensitise plates coated with the above collodion, the necessary length of stay in the silver bath is nearly twice as long as for an ordinary bromo-iodised plate.

There are one or two points which require a little explanation. The first is, as to the use of acetic instead of nitric acid in the silver bath. Nitric acid immediately decomposes eosine and cyanine, and not only is considerable colour sensitiveness lost, but the plates are foggy.

The second point is as to the preparation of the yellow-plate negative. Theoretically the red and blue, assuming that we are photographing the spectrum, should be equally opaque, and the yellow only bare glass, but practically the red end may be ignored, as any failure here is compensated for by the use of a carmine ink.

That three-colour negatives can be made direct in the camera by the wet-plate process is proved, but is the game worth the candle? If we take as unity for exposure that required to make a good half-tone negative on ordinary wet collodion from a print, or, better still, a transparency made by contact printing from one of the three negatives made on gelatine plates in the ordinary way, we shall find that we have first an increase of exposure of three times in consequence of the slowness of the colour-sensitised collodion, and then an increase of about three times again for the violet screen, an increase of about thirty for the green, and 180 for the orange screen; and we are compelled to arrive at the conclusion that direct three-colour half-tone negatives on wet collodion are not practicable so far as time-saving goes, and, unless we are using extremely powerful arc lamps for illuminating our subjects, the exposures will be so unduly prolonged as to introduce the trouble of the plates partly drying.

Then, again, if the half-tone negatives are made direct, we certainly lose one very valuable aid to successful reproduction; for, if we use dry plates in the first instance, and from these negatives make transparencies, either by contact or in the camera, we may alter considerably the tonality of the results by making these transparencies harder or softer. Unless absolutely correct negatives can be guaranteed the first time, it will be more satisfactory to make our three negatives in the ordinary way, and then the half-tone negatives, than to make the latter direct in the camera, whether on dry plates or wet collodion.

For those who wish to use collodion there is no better process than that of Hübl, described by Herr Pretzl in our issue of August 28.

Memorial to Fox Talbot.—We learn that, as a memorial to this distinguished man to whom photography is so much indebted, it is proposed to restore the chancel of Lacock Church, Wiltshire. Those of our readers who attended the Bath Photographic Convention will remember one of the excursions was in this direction.

Marvellous Röntgen Work.—According to accounts received from Berlin, Herr Dormann has obtained Röntgen sciographs through plates of iron twenty-two centimetres (about nine inches) thick, and has already taken upwards of fifty of such photographs. The experiments are to be continued by Professor Seaby, of the Charlottenburg Polytechnic Academy, he having taken a great interest in them.

Hypo-phosphorescence.—This term has been devised by Professor Silvanus P. Thompson to express the production by rays of light of vibrations more rapid than their own. As an example of this newly discovered state of vibration, he found that the rays of an arc light could so act upon a piece of "pine" as to cause a shadow to be produced by an object placed on the other side of the wood and against a sensitive plate; but, if a thin plate of aluminium were to be substituted for the pine, there was no action upon the plate.

Testing for the Presence of Acetylene.—Professor Clowes, in a paper read at the recent British Association meeting stated that this gas could not, when in a state of purity, be readily detected by its smell, and the smell would not, in any case, furnish a means of measuring the proportion present in the air; but the detection could be easily carried out by an adaptation of his method of ascertaining the presence of fire damp and coal gas in air. A small hydrogen flame showed a pale but well-defined "cup" in air containing any proportion of acetylene lower than the lowest explosive proportion. When the hydrogen flame was exposed to air, to be tested for acetylene in a darkened space, it was at once tinged yellowish-green.

Surveying by Photography.—As the same meeting was described a method for utilising photographs taken with an ordinary camera for filling in the details of a map. Mr. John Coles pointed out that the Surveyor-General of Canada had adopted the plan, and had produced good useful work by its means. In the discussion it was, however, pointed out that the weather was so important a factor in the matter that photography could never be depended upon for surveying of the highest character, though it would be very valuable in the surveying of mountainous districts and new countries.

Amusing Queries.—An evening contemporary that has a column devoted to queries and answers often has some very amusing ones as regards photography, and we have on one or two occasions treated our readers to a sample. Here are a couple more that appeared a few days ago, which are evidently photographic, though there is nothing to indicate to the readers that they in any way relate to photography. We here give them *verbatim*. "PLATES.—What are isochromatic and orthochromatic plates?—*W. B.*" "STAINS.—Is there a way of taking out pyro and also fixing stains

on clothes?—*Stains.*" It may be presumed, as the word "pyro" is used, that this is a photographic query, though it may be doubtful, inasmuch as most photographers are more interested in the removal of stains than in fixing them upon their clothes.

Conveyance of Gas Cylinders.—The lantern season is now well upon us, and we are sorry to see at some of the railway stations the same notices with reference to the carriage of charged gas cylinders that were issued last year. How far those restrictions will be carried out this season we are at present unaware. Up to the present, on some lines at least, the report of the committee of experts appointed by the Home Office seems to have had no effect. Of course, as we have said before, the railway companies can make their own rules and regulations, and need not be influenced by the committee's report. It is to be hoped, however, that the stringent regulations still prevailing on some lines will be, to some extent at least, relaxed. If they are not, there is little doubt that cylinders will often be carried surreptitiously as personal luggage, as we know was sometimes done last season.

The Rain in September.—Those amateur photographers who put off their annual holiday till September have had good cause to regret it. September is, however, as a rule, one of the best months of the year for outdoor photography. Some of the best pictures of the late Mr. Vernon Heath were taken in that month. This year's September has been an exceptional one, as the rainfall has been more than two and a half times its average, and has been accompanied by exceptionally heavy gales and storms. In London, 5·31 in. of rain was registered, and it is not since 1875 that 5 in. has been registered at Greenwich in a September, and only five times since 1841. The total rainfall for the summer, from April to September, was, at Greenwich, 11·10 in., and of this very nearly one-half fell in the latter month.

Apropos of the rough weather of last month, the gales must have sorely tried the roofs of many photographic studios, particularly those of the old type, and developed many leaks that were but little suspected before. When one journeys to town by rail, especially from the southern and eastern suburbs, where the trains are on a level with the housetops, one cannot help noticing the number of more or less dilapidated studios perched on the tops of houses or outbuildings, erected in the days of glass positives or Daguerreotypes, and at the same time wondering how they have withstood the elements for so long a period. One would surmise that, if the district surveyors in some of these neighbourhoods were as vigilant as they are in others when a new studio is to be built, many of these "glass houses" would be condemned as being unsafe, as many undoubtedly are, in a heavy gale of wind.

Ideal Statues.—At the unveiling, at Paisley, of a statue of the famous Scottish poet Burns, Lord Rosebery, who performed the ceremony, remarked that, manifold as are the statues of Burns, of busts or statues taken from life, there is not one, nor is there even a cast, taken after death. "We have," he said, "to some extent, therefore, to idealise our statues of Burns, though not so much as in the case of the statue of Highland Mary, which was erected the other day—a graceful tribute to a charming character, but one of whom we possess no likeness whatever. Still, of Burns we have nothing but canvas, and canvas that is not wholly satisfactory." Now, to many matter-of-fact people, it seems a little irrational to erect a statue of an individual of whom no portrait or likeness whatever exists. Yet idealised statues exist almost everywhere. Probably, however, if the parents of the individuals could again visit this earth, they would fail to recognise their own children.

In reading Lord Rosebery's speech we were forcibly reminded of an anecdote that has done duty in several different forms since its birth in the Daguerreotype days. It is this: An old lady waited on the artist saying she wanted a "daggeratype" of her son taken. Upon being told to bring the son to the studio, she replied she could not, as he was dead, but she had a very good description of him in an old passport, and she supposed that would do as well. Not only are statues idealised every day, but paintings also, and very differently, by different artists. One has only to walk through our National Gallery, or any of the Continental ones, and note the scores of, say, *Madonnas and Infants*, to see how wonderfully different each artist has idealised the portraits, no two being alike. Every painter has his own ideas as to what the Madonna was, or should have been like, and paints the features accordingly; so with sculptors, they portray a bust or a statue by idealisation according to their individual conceptions.

Photographic Lens-testing at Kew.—Our readers have on a previous occasion been put in possession of the methods adopted in Kew for testing photographic lenses. Just as by sending a thermometer, or a watch, &c., any one can, after paying a small fee, receive a clear statement as to its exactitude or its variations therefrom, so can the sender of a lens be informed of all its faults and excellences. Much was expected of this new departure at the time of its introduction; but, judging by figures, very few have availed themselves of the opportunities offered. According to the Report of the Kew Committee, just published in the proceedings of the Royal Society, the year 1894 saw no more than twenty-seven lenses submitted; and last year only about half that small number, fourteen being the tabulated figures. This must be very disappointing to the introducers of the system, which involves a very considerable amount of personal attention being given to each lens examined.

Rejuvenation of Defective Crookes' Tubes.—Mr. Ralph McNeill, of New York, says: "A little point which I have found out about focussing Crookes' tubes may be of interest, as I have not seen it in print. In use, the vacuum of the tube runs up, necessitating increasing the power of the coil to get the same results, and, after this increase becomes impracticable, heating the tube is resorted to. This is apt to destroy the tube by cracking it, unless very carefully done, and, even if safely done, it soon loses its power to restore the tube. It occurred to me that the increase of vacuum was due to the absorption of gases by the platinum anode, and, knowing that the negative pole threw off gas, I reversed the polarity of the tube. After working it in that way for half an hour, the tube was restored to full power, and I have practised this process for the past two months with perfect success and without injury to the tube. After an hour's run with the X rays I reversed it as above, and it is ready for another hour's run. The coil should be cut down in power when reversed, as there is danger of disintegrating the platinum and depositing it on the glass. I cut out half the battery power. The tube-makers recommend that very high vacuum tubes be sent them to have air admitted and repumped; but my method appears preferable, and, besides, saves their charge of three dollars and the time."

Gold and Silver in Sea Water.—For many years past enthusiasts have discussed the probability of extracting in paying quantities the silver, long known to be present, from sea water. More lately gold also has been shown to be a constituent of salt water. Quite recently our contemporary, the *Chemical News*, has been reprinting in its columns a paper by Mr. A. Liversidge, M.A., read before the Royal Society of New South Wales upon this subject. He has treated it in such an exhaustive manner that it is scarcely likely to be resuscitated after the *coup-de-grace* he has, unconsciously it may be, delivered. Photographers need feel no hopes that any project can be devised that will give them either cheap silver or cheap gold. To give some idea of the amount present, we may say that Mr. Liversidge found, for example, in three samples from Southern waters, quantities ranging from half a grain to just over a grain of gold per ton. His final verdict is that "at the present day it would probably not pay to extract the gold by itself, although it might as a by-product in the manufacture of salt, bromine," &c.; rather disappointing after, in the same paragraph, reckoning up the actual amount present in the whole of the ocean. Thus, reckoning on the above basis, and the most modern calculation

as to the bulk of the ocean, he points out that there would be, in all the seas and oceans of the globe, 75,000,000,000 tons of gold!

Photography at Balmoral.—The Queen's photographer at Ballater, Mr. Mylne, who had the honour of being summoned by Her Majesty, must have had a good business line at Balmoral last week. We read that the whole of one forenoon was taken up in photographing their Imperial Majesties and the Royal guests, so that the shooting party, which was to have started in the morning, did not go out till the afternoon. One of the principal groups taken included the Queen, the Emperor and Empress of Russia, the Prince of Wales, and the Grand Duchess Olga. Another group included the Princess of Wales, the Princess Victoria, Prince and Princess Charles of Denmark, the Emperor and Empress of Russia, the Duke and Duchess of Connaught, and several other Royal personages Other groups with the same illustrious personages in different costumes were taken; also groups of the Russian household, as well as the members of the Queen's household. It is seldom that any photographer has had the honour of taking such a number of negatives of Royal personages as were taken on this occasion. One of the daily papers takes quite a third of a column in enumerating the groups taken, and the dresses worn by those who figure in them. The day before, the detachment of the Scots Greys, of which the Czar is Honorary Colonel, that formed the military escort of the Emperor and Empress, was paraded on the green at Ballater and photographed. A day or two after, the Guard of Honour (Black Watch) were also photographed, Her Majesty being desirous that both these groups should be kept as mementoes of the Czar's visit to Scotland. On the visit to Mar Lodge, while the royal carriages were passing along the avenue, and when the party was being received by their host and hostess, "animatograph" photographs were taken at the rate, so it is said, of twelve hundred in ten seconds. Altogether, there has been no lack of photography at Balmoral during the past week.

BY THE WAY.

I HAVE had another rather rambling letter from Mr. A. Robertson, in which, *inter alia*, he gets the German Emperor and the Transvaal hopelessly mixed up with amateurs, professionals, and photographic dealers. The only material point of interest that I can gather from his communication is that he has discovered that I am a "traveller for the trade, and therefore have a foot on each of the two horses, as in the circus." Passing by the entirely novel revelation to me that photographic dealers send their travellers round the country on circus horses, it may interest Mr. Robertson to know that I have not the slightest commercial interest in photography, either as dealer, professional, or "shamateur," but have written on this subject purely from the common-sense point of view.

Mr. Robertson objects to my view that there is no legal barrier to prevent dealers and so-called amateurs trespassing on the domains of the legitimate professional if they so please, and he is great on the point of giving and receiving "fair play," as well as on the importance of the "trade" combining to put a stop to the nefarious practices of which he complains. Now, the trade *has* tried to combine to prevent its members running down prices so low as to make living impossible, and I will put the matter to him in another way by asking him if it is quite in consonance with his ideas of "fair play" to go dead against the wish of his fellow professionals by offering a single cabinet for one shilling, for this is what he offers, I notice, from the business card sent to me. It rather seems to me that his idea of fair play is somewhat one-sided—he may do as he pleases, but others may not. A far more manly view of the question is taken by a correspondent in a recent JOURNAL, "One of the Poor Slaughtered Ones," who openly declares for doing as he likes and letting others do the same.

Turning to another matter alluded to in my last—the pharmaceutical chemist and his vagaries, I cordially agree with one of your correspondents, that the "silly season" has been in full swing. It is always more or less "on," but it seems to me this year it began to grow in intensity on August 14, when the Pharmaceutical Society was heard for the first time through its humble agent, "W. Hampson;" and it culminated on September 11, when the same individual so freely took the bait held out for him, for I must confess that I had a strong suspicion that my mental picture of the average "chemist" would pretty closely fit the individual who exhibited such an indignant interest in the status of the Pharmaceutical Society. It was silly in the extreme on the part of an individual member, however eminent, to exhibit so much irritation on behalf of the Society as Mr. Hampson did in his first letter; it was sillier still to so hopelessly "give himself away" as he did in his second, by descending, as he did, from the lofty pedestal first assumed to the shop floor and broom, and to the performance of other duties that form no part whatever of the business of a pharmaceutical chemist as such.

I am not at all concerned in the mere verbiage that forms the greater part of Mr. Hampson's letter on page 591, but I should like to say a word or two in reply to his allusion to the "other subjects" in the chemists' (?) "exam." In my last communication I spoke of "*quasi* botany and *materia medica*" as being the only two subjects really essential for the apprentice to specially study, since—in the old days, at least—during his seven years of service, if any good at all, he would pick up a really practical knowledge of all the operative chemistry that it was ever intended the "pharmacist" should require. In the old days—I do not know how it may be now—most of the tinctures, powders, and preparations, as well as many of the salts used in pharmacy, were made on the premises, and the careful and industrious apprentice acquired an intimate and practical aequaintance with the preparation and composition of such things that would carry him through the exam. without any further "cramming." Now that the majority of such preparations come direct from the wholesale houses, the apprentice, and after him the full-blown chemist, has to rely mainly upon a book knowledge of their composition and characters, and this, as I stated previously, is most likely "crammed" into him with other matters during the last few months of his "time." What wonder, then, that in too many cases it is nearly all forgotten twelve months after the examination is passed?

I am quite aware that practical and analytical chemistry form a part, but not a very essential part, of the modern curriculum, but there is just where the trouble comes. A youth who manages to scrape through an examination in these subjects, that might possibly "satisfy the examiners" in the third and fourth form of an ordinary science school, straightway blossoms forth into an "analytical and pharmaceutical chemist by examination," all in large letters; and mark that the "analytical" comes first, because it is what puzzles him most, and therefore it looks most important. At the next stage he proceeds to the "making of analysis" of urine—*vide* Mr. Hampson—and other matters to his own satisfaction, no doubt, but possibly not to anybody else's. An old friend of my own was really worried into his grave by one of this class, who, by the mis-manipulation of some sulphate of copper and caustic potash and subsequent prescribing, first persuaded him that he was in the last stage of diabetes, and then tried to cure what he had not got! On the whole, I should be inclined to make answer to Mr. Hampson's query as to "our" knowledge of such subjects that they are never—cannot possibly be—"thorough," more possibly *quasi*, whatever he may mean by that; but, *most* probably, in the majority of cases, "none at all."

What has Mr. Hampson added to our knowledge of the subject under discussion, and what does his championship of the Pharmaceutical Society teach us? Simply that, while the Society, as was first alleged, keeps its eyes very wide open to any little infringements of its own "exclusive" rights, it works at if it does not openly encourage its members in embarking in branches of business which are none of theirs, and with which the much-boasted "charter" has nothing to do. Worse, the only two champions it can find appear to openly justify their undertaking work which is absolutely illegal. But, if Mr. Hampson is ready to "glory in his shame," what are we to think of a "member of the medical profession" who is ready to intrust his analytical work, however simple it may be, to a druggist who fills in the remainder of his time in the manner stated? I think the

medical men of Leigh, in Lancashire, owe it to themselves individually and collectively to repudiate the insinuation.

Mr. J. Pike's championship takes a much less objectionable form, and he attacks the question from an entirely different point of view, as he speaks in favour of the chemist individually rather than of the Society. It is quite true, as he says, that the business of the chemist abounds in anomalies; but who is to blame for them? Surely no one but the chemist himself, or his Society; and, to prove this, I need go no further than one of Mr. Pike's own instances, which is so comically absurd, as an argument from *his* side, that I can scarcely help thinking he intended it for a joke. Amongst other things, he complains of the public asking "for *liquorice* powder when they mean a compound of sulphur, senna, fennel, and sugar, &c." The "&c." he might have added, representing the liquorice. I turn up the first book of reference that comes to hand—*Gray's Supplement to the Pharmacopœia*, edited by no less an authority than Dr. Theophilus Redwood, Professor of Chemistry to the Pharmaceutical Society—and I find this mixture there described as "*Pulvis glycyrrhizæ compositus*," "*Pulvis pectoralis kurellæ*" ("compound liquorice powder"). These are the only names it bears, and I want to know what else Mr. Pike expects an innocent public to call it if they want to get it?

If the Pharmaceutical Society or chemists individually choose to name a compound after one of its ingredients, which forms only a sixth part of the whole, and which is perhaps the least active portion of the mixture, it does not seem fair that they should charge the public with introducing anomalies into their business. Who but the chemist, too, is chargeable with degrading carbonate of soda to simple "soda," dropping even the popular prefix of "washing," and bicarbonate to carbonate? Who but the *pharmaceutical*—I lay stress on the word—would think of selling or describing red oxide of iron as "*ferri carbonas*" or "carbonate of iron?" And I wonder, supposing I wanted carbonate of iron and received powdered hæmatite ore instead, whether I should have any ground of action against the "chemist" who sold it to me. Not a great while back I wanted some ferrous oxide, and went to the "chemist's" for it. I was told he had none, so I asked for "carbonate of iron," and got what I wanted; but I was surprised to find that the chemist himself thought, until he turned up his pharmacopœia, that, so far as this great and important corporation is concerned, the terms are synonymous.

But Mr. Pike's defence of the practice of chemists prescribing is a direct argument in favour of the other side. It was "Cosmos," not I, who mentioned this little weakness of the "poor chemist," and here we have its *raison-d'être;* like selling lenses, extracting teeth, making analysis, and a thousand-and-one other jobs that pertain to somebody else's business, it is avowedly to keep the money from going anywhere else, which is just what the poor chemist has all along been charged with. But even that explanation does not render an illegal action legal, and prescribing by chemists *is* illegal. It reminds me of the burglar's defence when asked what he had to say for himself: "If 'e's such a mug as to leave 'is door open all night, I should be a bigger to go past without sneaking something."

On the whole, however, Mr. Pike takes a more reasonable view of things than Mr. Hampson, and does not pretend to ignore undoubted facts. It is the high-and-mighty, omniscient side of the chemist's character that makes him such an objectionable and dangerous object, when his peculiarities are well marked, and it is not too much to say that the modern "chemist by examination" generally feels himself competent to undertake anything from dispensing to analysis or even the management of a plate factory. He is the sort of man, who, if you ask for bicarbonate of soda, could not think of serving it without labelling it "monosodic carbonate." It looks better, don't you know. That is, if he has been properly taught, but, as likely as not, he would give it you as di-sodic carbonate, as actually occurred to me, just to mention one more instance that recalls itself, and no amount of argument would convince the two learned young gentlemen of the difference between the terms "*di-acid*" and "di-sodic." A writer on the alkaline toning bath in the pages of the JOURNAL some years ago—who must, I think, have been a chemist of the pharmaceutical kind—gave his readers the valuable information that bicarbonate of soda, as compared with the ordinary carbonate, *contained twice the quantity of alkali*, and must therefore be used more sparingly.

Looking at the matter in a dispassionate manner, I don't think the Pharmaceutical Society's defenders have done it much good. Mr. Hampson has treated us to a number of mixed metaphors including that of the two horses yoked to opposite ends of the coach who "look foolish" because they accomplish so little. Following his lead, I would suggest that, when the two horses hitch themselves on to the tailboard of the pharmaceutical coach, they must both look and feel foolish at the vast amount of work they can jointly accomplish in the wrong direction.

The poor chemist has proved such an interesting subject that I have left myself no space to say a few words, as I had intended, on another topic of the day—artists or painters as Judges. I am sorry for this, because at the time I write the results of their deliberations over the exhibits in Hanover-square are not yet known, and could not therefore have in any way influenced my remarks. However, if the subject is not overdone in the interim, I will defer my views until next month.

DOGBERRY.

FOREIGN NEWS AND NOTES.

Line of Sight and Facial Angle.—An interesting article on this question, by Jean Paar, is published in the *Photographische Correspondenz*. Kampfer's method of determining the facial angle is by two crossed lines, one of them in the direction of the base of the forehead and the incisor teeth, and the other from the ear passage to the lower part of the nostril. The angle formed by these crossed lines is 90° in the higher races, 65° in the lower races, and 45° in the apes. The angle exceeds 90° in the Apollo Belvidere, and in the profile of the Zeus of Otricoli it exceeds 100°. Kaempfer explains this abnormal or superhuman angle by attributing to the sculptors a desire to express the superhuman intelligence of the gods by a superhuman facial angle. On the other hand, Professor Vogel, in his *Handbook of Photography*, maintains that the lofty profile adopted by antique sculptors depends upon practical considerations. Jean Paar thinks there is some confirmation of this in the head of Hermes by Phidias. But Paar advances a theory of his own, based upon considerations of perspective. In the Apollo Belvidere the line of sight was important. The statue was intended to be placed on a moderately low pedestal, and the sculptor apparently intended that it should be viewed with the line of sight directed centrally. The larger facial angle, if intentionally designed, would then apparently give the warlike god of light an expression of higher intelligence. But art and nature seem strangely at variance, and Paar remarks that Voltaire, Neander, and many others, were object-lessons for the Darwinian theory. The facial angle in the two first-mentioned men was probably between 60° and 70°, but in the brains of both was stored up more intelligence than in many a dozen specimens of the bovine type with facial angle of 90°.

Röntgen and Lenard.—In the *Photographisches Wochenblatt*, R. Ed. Liesegang discusses the question whether the Röntgen and the cathode rays are related to each other or not. Battelli and Garbasso have come to the conclusion "that it is not logical to believe that the cathode rays, which cannot be diverted by the magnet, are different from the Röntgen rays. Real characteristic differences are wanting. The simplest conclusion is that the cathode rays do not differ from each other in their essential properties more than, for example, two flames of different colour." Röntgen, in his treatise, affirmed as an important difference that Lenard's rays were only perceptible at a few centimetres' distance from the tube, whereas his own could be observed at a distance of several metres; also that the cathode rays were subject to magnetic influence, whilst the new rays were not. Neither of these statements will hold water. Lenard has been able to observe the cathode rays at a considerable distance under favourable conditions, and Goldstein has shown that there are cathode rays that are uninfluenced by the magnet. As both do not agree in all respects, it may be read between the lines of what has been published that there may be a difference in wavelength after the manner of red and blue light. But this is incorrect, the difference being more like that between white and monochromatic light. The properties of the cathode rays indicate that we have to deal with a mixture of different sorts of rays, more or less, or not at all, influenced by the magnet, in the same way that white

light is broken up by the prism. As the blue rays are a component of white light, so the Röntgen rays form part of the cathode rays. If we make a piece of iron red hot, it emits red light only. Heat it until white-hot, and it will then emit red, green, and blue light. It is the same with a Crookes' tube, the degree of exhaustion acts similarly to the creation of light by heat. A low vacuum will permit the emission of only those rays corresponding to red light, and strongly influenced by the magnet. They contain few Röntgen rays, and penetrate the glass very badly, and for this reason Lenard had to use an aluminium window. Röntgen used a higher vacuum, and obtained the rays uninfluenced by the magnet corresponding to blue light. If we hold a blue glass in front of the red-hot iron, the latter is invisible, but if we hold it before the white-hot iron we see blue light. Röntgen similarly separates the rays which are susceptible to the magnet from those which are not by allowing them to pass through the thickness of glass. By means of a magnet a species of cathode spectrum may be obtained. In this way it may become possible to isolate a special kind of ray.

Granularity in Carbon Printing.—Besides the usual method of coating with collodion for avoidance of this trouble, Raimund Rapp, in *Die Photographie*, recommends the use of gelatine and chrome alum. A five per cent. gelatine solution is prepared by first soaking in cold water for an hour and then raising the temperature to 35° or 40° C. Into this is dropped with constant vigorous stirring sufficient of a six per cent. chrome alum solution until it thickens. For half a litre of gelatine solution about thirteen to sixteen cubic centimetres of the chrome alum solution are necessary. Now add drop by drop sufficient glacial acetic acid until the whole is again brought into a fluid state, and then filter. Before the cleaned glass plates are coated with the solution, they should be given a narrow edging. When this is dry, the plates are levelled and coated in a room free from dust. If the fault arises from too rapid drying of the tissue, it may be obviated by placing a few saucers of water in the drying room. In warm weather it is advisable to cool the water in which the prints are soaked with ice; also be careful to keep the tissue below the surface of the water.

A New Developer.—The *Photographisches Archiv* states that E. Ackermann has discovered that a strong reducing fluid, suitable for development, may be formed by heating in a closed vessel for ten hours, at 100 C., 2 grammes of sulphate of quinine, 8 grammes of powdered zinc, and 40 cubic centimetres of water.

The Fire at Montpellier.—Referring to the unfortunate destruction of the Montpellier Exhibition by fire, Mr. Léon Vidal, in *le Moniteur de la Photographie*, draws attention to the irreparable loss of valuable documents, paintings, and other works of art from such causes. It is usually said "the loss was covered by insurance," but no insurance can repair damage of this kind. Ought not photographs to be made of all precious documents, and copies deposited in various collections? It would then, at least, be possible to reproduce, in a measure, the original, should they be lost by fire or other misadventure. In France there is a Museum of Photographic Documents, which assists this end, but it is unimportant where such collections are preserved, provided proper catalogues are kept and the works are accessible to those interested in them. This is a matter requiring serious and urgent attention.

Rules for Printing.—In the *Photographische Mittheilungen*, P. Hanneke criticises the usual instructions to print until the shadows begin to bronze and the high lights are affected. It would be more correct to say that the prints should be taken from the frame when they are rather darker than required when toned; but one should be careful not to print too slowly, and to tone directly after printing, unless the combined bath is used. The frames also should not be opened in a temperature different from where the printing takes place. If the prints are printed too slowly, or if they are kept any time between printing and toning, it will be difficult to produce bluish tones, especially with albumenised paper. For blue tones on collodio-chloride paper a preliminary bath, to which ammonia is added, is frequently recommended. In this way a fine, warm blue, with a trace of purple in it, can be obtained, but the prints must be well washed before toning. Fresh paper should be printed rather deeper than old, and yellowish paper should be left longer in the fixing bath. The normal time for fixing is fifteen minutes.

A Good Cat Story.—In the *Bulletin du Photo Club de Paris* we read of the following incident at the château of Dobroslawitz. Count W—— is an enthusiastic amateur photographer, and has trained some of his servants to undertake some of the minor functions of the laboratory assistant. One of the valets was in the habit of leaving candle ends about and remnants of food. This attracted the rats from the stables, and caused much trouble and annoyance. Infallible traps were ordered from Paris, but to no purpose. Phosphorus paste and other poisons were not to be had; but a visitor, finding a stuffed cat, a former favourite of the household, he thus ingeniously defeated the wary rodents. The eyes of the cat were removed and replaced by a couple of lenses from a toy microscope. The Count's Secretary placed two small incandescent lamps behind the lenses. These were connected with a battery, and the cat, thus equipped, was placed in the laboratory near the suspected entrance of the rats. A very delicate connexion was made with the lamps, and covered with a cake made of flour, melted fat, oil, and powdered sugar. This was placed in such a manner that a rat seizing it would immediately pass the current into pussy's eyes. The Count had no faith in the arrangement, but the watchman undertook to keep an eye on the laboratory, and the first night the cat won a complete victory. The rats had scarcely touched the cake when the eyes of the cat were illuminated with a greenish light, and terrified the devastators so utterly that they fled stupefied and never returned again. An electric bell was rung at the same time as the eyes were illuminated. The watchman was immediately upon the spot, found the cake partly gone, and the eyes of the cat still glowing with their deathly light.

A ROYAL ALBUM.

We have had the opportunity of examining an album of photographs that has been presented to Her Majesty the Queen by Messrs. Johnston & Hoffman, the well-known photographers of Calcutta, who intrusted the binding and the illumination of the pages to Messrs. Marcus Ward & Co., of London and Belfast. The album contains fifty-seven 12 × 10 portraits in platinum of the ruling princes of India, taken especially for the purpose by Messrs. Johnston & Hoffman, and sixty-six smaller views in the various states, interiors of palaces, &c. The photographs are of extremely good quality, aside of the very great interest attaching to them.

The mounting, lettering, and binding are the work of Messrs. Marcus Ward & Co., who also executed the very tasteful Oriental illumination surrounding the smaller photographs. The front cover of the album is in cashmere silver *repoussé* work, the back cover being gold embroidery with a silver rim. The back of the cover is in royal blue Levant morocco. The inscription on a silver plate states that the album is presented by permission to Her Majesty. The panels of the casket in which the album is contained are in Bombay inlaid carved black wood, lined with blue silk, and the sides and front of the casket fall down, so that the album need not be taken from it when it is desired to examine it. The album is a splendid production, and reflects great credit on Messrs. Johnston & Hoffman.

CALCIUM CARBIDE AND ACETYLENE.*

This compound has created an enormous sensation in the financial world, or at least in the speculative part of it, during the last year or so. As far as its discovery in America goes it appears to have been a mere matter of chance, an invention in the literal meaning of the word. The formation of calcium carbide from carbon and lime seems to be a mere question of temperature, and to have nothing to do with electrolysis. It may be that lime and carbon do not react until the lime is fused or the carbon volatilised, and that the temperature of the electric furnace is needed to bring this result about. It is probable, however, that the very high temperature is necessary to bring about the reaction, apart altogether from getting the lime and carbon into contact. I have tried some experiments with an oxygen furnace, and have not succeeded in making calcium carbide even when I used a solvent for the lime, so that there was no doubt that it came into contact with the carbon. These experiments were not tried thoroughly enough to be conclusive, but they tend to show that an exceedingly high temperature is needed. It is hardly necessary to say that an oxygen furnace, that is to say, an injection furnace fed with an oxygen and coal-gas blowpipe, gives a pretty high temperature.

The future of calcium carbide depends very largely on its cost of manufacture. It is, of course, very absurd to take the cost of coal, lime, and energy, and, calling that the cost of the carbide, to compare the cost of a candle-power-hour with that of gas as charged to the consumer.

* From a Cantor Lecture on *Applied Electro-Chemistry*, delivered at the Society of Arts.

The prime cost of gas delivered into the "hydraulic main" would be the right thing to compare in such a case, and would tell a very different story. On the other hand, the distribution of acetylene may well be much more simple in proportion than that of coal gas. If it is to be delivered by pipes, its only advantage, as far as distribution is concerned, is that the pipes will be smaller. This would make but little difference in the total cost of distribution, as it only reduces the capital sunk in mains a little. The cost of laying them would not be very much reduced.

The first thing is to get some idea of the cost of calcium carbide. The estimates given vary enormously, as very little has been published as to actual cost of manufacture. It seems probable, however, that the cost of manufacture—that is to say, the cost of lime, coke, carbons, labour, and energy, taking everything at a farthing per kilowatt hour, will be a little over 6*l*. If water is used, the price comes out a little lower; but, as already explained, water power must not be reckoned upon too much, as rents will probably go up soon. It is best to be on the safe side, so we may perhaps take 10*l*. a ton as the final price of electrically made calcium carbide, capable of giving five cubic feet of acetylene per pound, packed and delivered on rail, after paying manufacturers' profits and all charges. This seems a low price, and it may be said that the various aluminium works have all the plant ready, and know exactly the cost of manufacture, and have reduced the price as far as it will go already. The business has really hardly commenced, however, and there is little doubt that the processes will be cheapened. At present it is the roughest and crudest method imaginable.

Let us assume the final price to be 10*l*. a ton, and see exactly what its future may be at that figure. Allowing five cubic feet of acetylene per pound, this gives, in round numbers, 18*s*. per 1000 cubic feet. Calcium carbide is not acetylene, however. Suppose the treatment with water raises the acetylene to 20*s*., and that it gives 20 times as much light as coal gas, it would then correspond with gas at 1*s*. per 1000 cubic feet. Now let us look at the price of gas. A ton of coal at, say, 10*s*., gives 10,000 cubic feet of gas, so gas should be 1*s*. per 1000 cubic feet; but the ton of coal gives 15 cwt. or so of gas coke, which is worth something, and over 100 lbs. of tar, which is valuable, and 20 gallons or so of ammonia liquor. Some of the 15 cwt. of coke is used to heat the retort benches, and labour, &c., has to be paid for, but still the actual value of gas at the hydraulic main is really only a few pence per 1000 cubic feet, and acetylene has no chance in comparison. The common practice of taking the price—generally the prime cost—of carbide of calcium, reckoning from it the price of acetylene, and comparing it with the price of delivered coal gas, is absurd. In addition, the great difference in lighting power comes in when the acetylene burner, though using little gas, is giving a very powerful light. Except in sitting-rooms, people want small lights about their houses, and they want to be able to turn them down at will.

Acetylene may be used for enriching coal gas. Whether it will pay depends very much on the local conditions. Cannel coal is usually employed when enrichment is necessary. The prime cost of gas at any works depends on the price of coal and labour, and on the selling price of coke, tar, and ammonia. The cost of scrubbing and purifying would have to be incurred in making acetylene on the large scale, and the cost of distribution by pipes and collection would be about the same in both cases. It is impossible, however, to give any answer as to whether it would pay to enrich coal gas, unless one knows the real cost price of gas in a given case. Thus, to take a rough example, suppose crude gas costs 6*d*. a thousand cubic feet, so that acetylene costs forty times as much. Adding 3 per cent. of acetylene would about double its lighting power, so that to replace 1000 cubic feet of gas we would have 500 cubic feet costing 3*d*., and 15 of acetylene costing over 3½*d*. It is, therefore, clear that it will not pay to enrich with 3 per cent. of acetylene at these prices. I have not worked out figures to find the best enrichment for each relation of values of acetylene and coal gas, for it seems clear that, unless the cost of carbide is much less, or the cost of crude gas much greater than here assumed, there is no chance of its being utilised in that way. A public company does not make improvements if it can help it, and of all public companies, gas companies, owing to their constitution and the sliding-scale arrangement, are least likely to adopt such methods as enriching gas, even with the by-products of electric lighting companies, who make carbide to get decent load factors.

In addition to this, gas is not used only for lighting. It is very largely used now for heating purposes, and the incandescent mantle has come to stay, and people with stoves and Welsbach burners would strongly object to having their gas bills doubled, and their gas contaminated with a body which necessitates their renewing all their gas fittings and removing all copper and brass taps and couplings.

It does not look, therefore, as if acetylene will compete with gas at present. It may be a different matter in other countries. In the United States, for instance, gas is generally very dear. I had charge of works in Boston some years ago, and we paid 10*s*. per 1000 for gas. One shudders to think what it must cost in outlying districts. The enormous strides made by the electric light in America is not owing to the good electrical engineers, but to the bad gas-producers. Perhaps the gas works are run by the urban authorities; this would account for anything. If sulphate of ammonia does not fetch good prices in America, and if tar distilling and the manufacture of dyes is not brought to the perfection they are in Europe, it is quite probable that acetylene has a much greater future there than over here, especially as, in proportion to the inhabitants, water power is much more plentiful, so that power prices may remain low for a very long time.
